

PROBLEM 1.1

KNOWN: Thermal conductivity, thickness and temperature difference across a sheet of rigid extruded insulation.

FIND: (a) The heat flux through a $2\text{ m} \times 2\text{ m}$ sheet of the insulation, and (b) The heat rate through the sheet.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x -direction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: From Equation 1.2 the heat flux is

$$q_x'' = -k \frac{dT}{dx} = k \frac{T_1 - T_2}{L}$$

Solving,

$$q_x'' = 0.029 \frac{\text{W}}{\text{m} \cdot \text{K}} \times \frac{10 \text{ K}}{0.02 \text{ m}}$$

$$q_x'' = 14.5 \frac{\text{W}}{\text{m}^2} \quad <$$

The heat rate is

$$q_x = q_x'' \cdot A = 14.5 \frac{\text{W}}{\text{m}^2} \times 4 \text{ m}^2 = 58 \text{ W} \quad <$$

COMMENTS: (1) Be sure to keep in mind the important distinction between the heat flux (W/m^2) and the heat rate (W). (2) The direction of heat flow is from hot to cold. (3) Note that a temperature *difference* may be expressed in kelvins or degrees Celsius.

PROBLEM 1.2

KNOWN: Inner surface temperature and thermal conductivity of a concrete wall.

FIND: Heat loss by conduction through the wall as a function of outer surface temperatures ranging from -15 to 38°C .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x -direction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: From Fourier's law, if q''_x and k are each constant it is evident that the gradient, $dT/dx = -q''_x/k$, is a constant, and hence the temperature distribution is linear. The heat flux must be constant under one-dimensional, steady-state conditions; and k is approximately constant if it depends only weakly on temperature. The heat flux and heat rate when the outside wall temperature is $T_2 = -15^\circ\text{C}$ are

$$q''_x = -k \frac{dT}{dx} = k \frac{T_1 - T_2}{L} = 1 \text{ W/m}\cdot\text{K} \frac{25^\circ\text{C} - (-15^\circ\text{C})}{0.30 \text{ m}} = 133.3 \text{ W/m}^2. \quad (1)$$

$$q_x = q''_x \times A = 133.3 \text{ W/m}^2 \times 20 \text{ m}^2 = 2667 \text{ W}. \quad (2) \quad \leftarrow$$

Combining Eqs. (1) and (2), the heat rate q_x can be determined for the range of outer surface temperature, $-15 \leq T_2 \leq 38^\circ\text{C}$, with different wall thermal conductivities, k .

For the concrete wall, $k = 1 \text{ W/m}\cdot\text{K}$, the heat loss varies linearly from $+2667 \text{ W}$ to -867 W and is zero when the inside and outer surface temperatures are the same. The magnitude of the heat rate increases with increasing thermal conductivity.

COMMENTS: Without steady-state conditions and constant k , the temperature distribution in a plane wall would not be linear.

PROBLEM 1.3

KNOWN: Dimensions, thermal conductivity and surface temperatures of a concrete slab. Efficiency of gas furnace and cost of natural gas.

FIND: Daily cost of heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady state, (2) One-dimensional conduction, (3) Constant properties.

ANALYSIS: The rate of heat loss by conduction through the slab is

$$q = k(LW) \frac{T_1 - T_2}{t} = 1.4\text{ W/m}\cdot\text{K} (11\text{ m} \times 8\text{ m}) \frac{7^\circ\text{C}}{0.20\text{ m}} = 4312\text{ W} \quad <$$

The daily cost of natural gas that must be combusted to compensate for the heat loss is

$$C_d = \frac{q C_g}{\eta_f} (\Delta t) = \frac{4312\text{ W} \times \$0.01/\text{MJ}}{0.9 \times 10^6\text{ J/MJ}} (24\text{ h/d} \times 3600\text{ s/h}) = \$4.14/\text{d} \quad <$$

COMMENTS: The loss could be reduced by installing a floor covering with a layer of insulation between it and the concrete.

PROBLEM 1.4

KNOWN: Heat flux and surface temperatures associated with a wood slab of prescribed thickness.

FIND: Thermal conductivity, k , of the wood.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x -direction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: Subject to the foregoing assumptions, the thermal conductivity may be determined from Fourier's law, Eq. 1.2. Rearranging,

$$k = q''_x \frac{L}{T_1 - T_2} = 40 \frac{\text{W}}{\text{m}^2} \frac{0.05 \text{ m}}{(40 - 20)^\circ \text{C}}$$

$$k = 0.10 \text{ W / m} \cdot \text{K}.$$

<

COMMENTS: Note that the $^\circ \text{C}$ or K temperature units may be used interchangeably when evaluating a temperature difference.

PROBLEM 1.5

KNOWN: Inner and outer surface temperatures of a glass window of prescribed dimensions.

FIND: Heat loss through window.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x -direction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: Subject to the foregoing conditions the heat flux may be computed from Fourier's law, Eq. 1.2.

$$q''_x = k \frac{T_1 - T_2}{L}$$
$$q''_x = 1.4 \frac{\text{W}}{\text{m}\cdot\text{K}} \frac{(15-5)^\circ\text{C}}{0.005\text{m}}$$
$$q''_x = 2800\text{ W/m}^2.$$

Since the heat flux is uniform over the surface, the heat loss (rate) is

$$q = q''_x \times A$$
$$q = 2800\text{ W/m}^2 \times 3\text{m}^2$$
$$q = 8400\text{ W}.$$

<

COMMENTS: A linear temperature distribution exists in the glass for the prescribed conditions.

PROBLEM 1.6

KNOWN: Width, height, thickness and thermal conductivity of a single pane window and the air space of a double pane window. Representative winter surface temperatures of single pane and air space.

FIND: Heat loss through single and double pane windows.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction through glass or air, (2) Steady-state conditions, (3) Enclosed air of double pane window is stagnant (negligible buoyancy induced motion).

ANALYSIS: From Fourier's law, the heat losses are

$$\text{Single Pane: } q_g = k_g A \frac{T_1 - T_2}{L} = 1.4 \text{ W/m} \cdot \text{K} \left(2 \text{ m}^2 \right) \frac{35^\circ \text{C}}{0.005 \text{ m}} = 19,600 \text{ W} \quad <$$

$$\text{Double Pane: } q_a = k_a A \frac{T_1 - T_2}{L} = 0.024 \left(2 \text{ m}^2 \right) \frac{25^\circ \text{C}}{0.010 \text{ m}} = 120 \text{ W} \quad <$$

COMMENTS: Losses associated with a single pane are unacceptable and would remain excessive, even if the thickness of the glass were doubled to match that of the air space. The principal advantage of the double pane construction resides with the low thermal conductivity of air (~ 60 times smaller than that of glass). For a fixed ambient outside air temperature, use of the double pane construction would also increase the surface temperature of the glass exposed to the room (inside) air.

PROBLEM 1.7

KNOWN: Dimensions of freezer compartment. Inner and outer surface temperatures.

FIND: Thickness of styrofoam insulation needed to maintain heat load below prescribed value.

SCHEMATIC:

ASSUMPTIONS: (1) Perfectly insulated bottom, (2) One-dimensional conduction through 5 walls of area $A = 4\text{m}^2$, (3) Steady-state conditions, (4) Constant properties.

ANALYSIS: Using Fourier's law, Eq. 1.2, the heat rate is

$$q = q'' \cdot A = k \frac{\Delta T}{L} A_{\text{total}}$$

Solving for L and recognizing that $A_{\text{total}} = 5 \times W^2$, find

$$L = \frac{5 k \Delta T W^2}{q}$$

$$L = \frac{5 \times 0.03 \text{ W/m} \cdot \text{K} [35 - (-10)]^\circ \text{C} (4\text{m}^2)}{500 \text{ W}}$$

$$L = 0.054\text{m} = 54\text{mm}.$$

<

COMMENTS: The corners will cause local departures from one-dimensional conduction and a slightly larger heat loss.

PROBLEM 1.8

KNOWN: Dimensions and thermal conductivity of food/beverage container. Inner and outer surface temperatures.

FIND: Heat flux through container wall and total heat load.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer through bottom wall, (3) Uniform surface temperatures and one-dimensional conduction through remaining walls.

ANALYSIS: From Fourier's law, Eq. 1.2, the heat flux is

$$q'' = k \frac{T_2 - T_1}{L} = \frac{0.023 \text{ W/m} \cdot \text{K} (20 - 2)^\circ \text{C}}{0.025 \text{ m}} = 16.6 \text{ W/m}^2 \quad <$$

Since the flux is uniform over each of the five walls through which heat is transferred, the heat load is

$$q = q'' \times A_{\text{total}} = q'' [H(2W_1 + 2W_2) + W_1 \times W_2]$$
$$q = 16.6 \text{ W/m}^2 [0.6\text{m}(1.6\text{m} + 1.2\text{m}) + (0.8\text{m} \times 0.6\text{m})] = 35.9 \text{ W} \quad <$$

COMMENTS: The corners and edges of the container create local departures from one-dimensional conduction, which increase the heat load. However, for $H, W_1, W_2 \gg L$, the effect is negligible.

PROBLEM 1.9

KNOWN: Masonry wall of known thermal conductivity has a heat rate which is 80% of that through a composite wall of prescribed thermal conductivity and thickness.

FIND: Thickness of masonry wall.

SCHEMATIC:

ASSUMPTIONS: (1) Both walls subjected to same surface temperatures, (2) One-dimensional conduction, (3) Steady-state conditions, (4) Constant properties.

ANALYSIS: For steady-state conditions, the conduction heat flux through a one-dimensional wall follows from Fourier's law, Eq. 1.2,

$$q'' = k \frac{\Delta T}{L}$$

where ΔT represents the difference in surface temperatures. Since ΔT is the same for both walls, it follows that

$$L_1 = L_2 \frac{k_1}{k_2} \cdot \frac{q_2''}{q_1''}.$$

With the heat fluxes related as

$$q_1'' = 0.8 q_2''$$

$$L_1 = 100 \text{ mm} \frac{0.75 \text{ W/m}\cdot\text{K}}{0.25 \text{ W/m}\cdot\text{K}} \times \frac{1}{0.8} = 375 \text{ mm.} \quad <$$

COMMENTS: Not knowing the temperature difference across the walls, we cannot find the value of the heat rate.

PROBLEM 1.10

KNOWN: Thickness, diameter and inner surface temperature of bottom of pan used to boil water. Rate of heat transfer to the pan.

FIND: Outer surface temperature of pan for an aluminum and a copper bottom.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction through bottom of pan.

ANALYSIS: From Fourier's law, the rate of heat transfer by conduction through the bottom of the pan is

$$q = kA \frac{T_1 - T_2}{L}$$

Hence,

$$T_1 = T_2 + \frac{qL}{kA}$$

where $A = \pi D^2 / 4 = \pi (0.2\text{m})^2 / 4 = 0.0314 \text{ m}^2$.

$$\text{Aluminum: } T_1 = 110^\circ\text{C} + \frac{600\text{W}(0.005 \text{ m})}{240 \text{ W/m} \cdot \text{K} (0.0314 \text{ m}^2)} = 110.40^\circ\text{C} \quad <$$

$$\text{Copper: } T_1 = 110^\circ\text{C} + \frac{600\text{W}(0.005 \text{ m})}{390 \text{ W/m} \cdot \text{K} (0.0314 \text{ m}^2)} = 110.24^\circ\text{C} \quad <$$

COMMENTS: Although the temperature drop across the bottom is slightly larger for aluminum (due to its smaller thermal conductivity), it is sufficiently small to be negligible for both materials. To a good approximation, the bottom may be considered *isothermal* at $T \approx 110^\circ\text{C}$, which is a desirable feature of pots and pans.

PROBLEM 1.11

KNOWN: Dimensions and thermal conductivity of a chip. Power dissipated on one surface.

FIND: Temperature drop across the chip.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Uniform heat dissipation, (4) Negligible heat loss from back and sides, (5) One-dimensional conduction in chip.

ANALYSIS: All of the electrical power dissipated at the back surface of the chip is transferred by conduction through the chip. Hence, from Fourier's law,

$$P = q = kA \frac{\Delta T}{t}$$

or

$$\Delta T = \frac{t \cdot P}{kW^2} = \frac{0.001 \text{ m} \times 4 \text{ W}}{150 \text{ W/m} \cdot \text{K} (0.005 \text{ m})^2}$$

$$\Delta T = 1.1^\circ \text{ C.}$$

<

COMMENTS: For fixed P, the temperature drop across the chip decreases with increasing k and W, as well as with decreasing t.

PROBLEM 1.12

KNOWN: Heat flux gage with thin-film thermocouples on upper and lower surfaces; output voltage, calibration constant, thickness and thermal conductivity of gage.

FIND: (a) Heat flux, (b) Precaution when sandwiching gage between two materials.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat conduction in gage, (3) Constant properties.

ANALYSIS: (a) Fourier's law applied to the gage can be written as

$$q'' = k \frac{\Delta T}{\Delta x}$$

and the gradient can be expressed as

$$\frac{\Delta T}{\Delta x} = \frac{\Delta E/N}{S_{AB}d}$$

where N is the number of differentially connected thermocouple junctions, S_{AB} is the Seebeck coefficient for type K thermocouples (A-chromel and B-alumel), and $\Delta x = d$ is the gage thickness. Hence,

$$q'' = \frac{k\Delta E}{NS_{AB}d}$$

$$q'' = \frac{1.4 \text{ W/m} \cdot \text{K} \times 350 \times 10^{-6} \text{ V}}{5 \times 40 \times 10^{-6} \text{ V/}^\circ\text{C} \times 0.25 \times 10^{-3} \text{ m}} = 9800 \text{ W/m}^2.$$

<

(b) The major precaution to be taken with this type of gage is to match its thermal conductivity with that of the material on which it is installed. If the gage is bonded between laminates (see sketch above) and its thermal conductivity is significantly different from that of the laminates, one dimensional heat flow will be disturbed and the gage will read incorrectly.

COMMENTS: If the thermal conductivity of the gage is lower than that of the laminates, will it indicate heat fluxes that are systematically high or low?

PROBLEM 1.13

KNOWN: Hand experiencing convection heat transfer with moving air and water.

FIND: Determine which condition feels colder. Contrast these results with a heat loss of 30 W/m^2 under normal room conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Temperature is uniform over the hand's surface, (2) Convection coefficient is uniform over the hand, and (3) Negligible radiation exchange between hand and surroundings in the case of air flow.

ANALYSIS: The hand will feel colder for the condition which results in the larger heat loss. The heat loss can be determined from Newton's law of cooling, Eq. 1.3a, written as

$$q'' = h(T_s - T_{\infty})$$

For the air stream:

$$q''_{\text{air}} = 40 \text{ W/m}^2 \cdot \text{K} [30 - (-5)] \text{ K} = 1,400 \text{ W/m}^2 \quad <$$

For the water stream:

$$q''_{\text{water}} = 900 \text{ W/m}^2 \cdot \text{K} (30 - 10) \text{ K} = 18,000 \text{ W/m}^2 \quad <$$

COMMENTS: The heat loss for the hand in the water stream is an order of magnitude larger than when in the air stream for the given temperature and convection coefficient conditions. In contrast, the heat loss in a normal room environment is only 30 W/m^2 which is a factor of 400 times less than the loss in the air stream. In the room environment, the hand would feel comfortable; in the air and water streams, as you probably know from experience, the hand would feel uncomfortably cold since the heat loss is excessively high.

PROBLEM 1.14

KNOWN: Power required to maintain the surface temperature of a long, 25-mm diameter cylinder with an imbedded electrical heater for different air velocities.

FIND: (a) Determine the convection coefficient for each of the air velocity conditions and display the results graphically, and (b) Assuming that the convection coefficient depends upon air velocity as $h = CV^n$, determine the parameters C and n .

SCHEMATIC:

ASSUMPTIONS: (1) Temperature is uniform over the cylinder surface, (2) Negligible radiation exchange between the cylinder surface and the surroundings, (3) Steady-state conditions.

ANALYSIS: (a) From an overall energy balance on the cylinder, the power dissipated by the electrical heater is transferred by convection to the air stream. Using Newton's law of cooling on a per unit length basis,

$$P'_e = h(\pi D)(T_s - T_\infty)$$

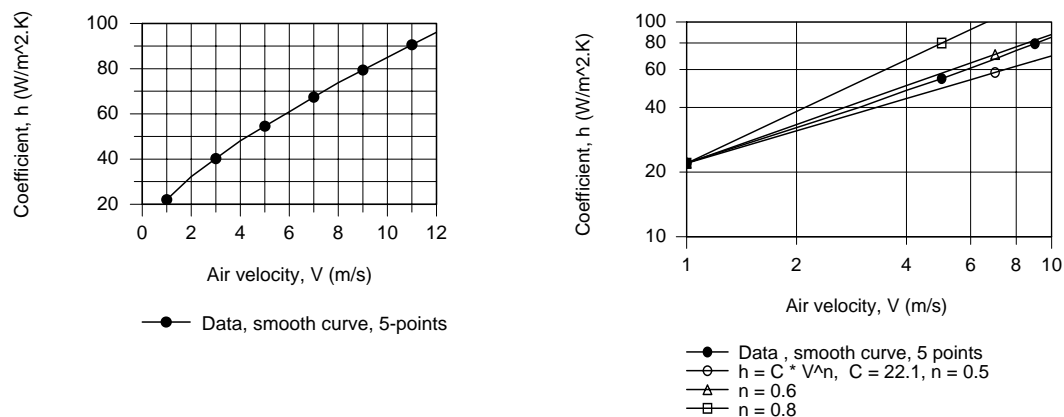

where P'_e is the electrical power dissipated per unit length of the cylinder. For the $V = 1$ m/s condition, using the data from the table above, find

$$h = 450 \text{ W/m} / \pi \times 0.025 \text{ m} (300 - 40)^\circ \text{C} = 22.0 \text{ W/m}^2 \cdot \text{K}$$

Repeating the calculations, find the convection coefficients for the remaining conditions which are tabulated above and plotted below. Note that h is not linear with respect to the air velocity.

(b) To determine the (C, n) parameters, we plotted h vs. V on log-log coordinates. Choosing $C = 22.12$ W/m²·K(s/m) ^{n} , assuring a match at $V = 1$, we can readily find the exponent n from the slope of the h vs. V curve. From the trials with $n = 0.8, 0.6$ and 0.5 , we recognize that $n = 0.6$ is a reasonable choice.

Hence, $C = 22.12$ and $n = 0.6$.

COMMENTS: Radiation may not be negligible, depending on surface emissivity.

PROBLEM 1.15

KNOWN: Long, 30mm-diameter cylinder with embedded electrical heater; power required to maintain a specified surface temperature for water and air flows.

FIND: Convection coefficients for the water and air flow convection processes, h_w and h_a , respectively.

SCHEMATIC:

ASSUMPTIONS: (1) Flow is cross-wise over cylinder which is very long in the direction normal to flow.

ANALYSIS: The convection heat rate from the cylinder per unit length of the cylinder has the form

$$q' = h(\pi D) (T_s - T_\infty)$$

and solving for the heat transfer convection coefficient, find

$$h = \frac{q'}{\pi D (T_s - T_\infty)}.$$

Substituting numerical values for the water and air situations:

$$\text{Water} \quad h_w = \frac{28 \times 10^3 \text{ W/m}}{\pi \times 0.030 \text{ m} (90 - 25)^\circ \text{ C}} = 4,570 \text{ W/m}^2 \cdot \text{K} <$$

$$\text{Air} \quad h_a = \frac{400 \text{ W/m}}{\pi \times 0.030 \text{ m} (90 - 25)^\circ \text{ C}} = 65 \text{ W/m}^2 \cdot \text{K}. <$$

COMMENTS: Note that the air velocity is 10 times that of the water flow, yet

$$h_w \approx 70 \times h_a.$$

These values for the convection coefficient are typical for forced convection heat transfer with liquids and gases. See Table 1.1.

PROBLEM 1.16

KNOWN: Dimensions of a cartridge heater. Heater power. Convection coefficients in air and water at a prescribed temperature.

FIND: Heater surface temperatures in water and air.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) All of the electrical power is transferred to the fluid by convection, (3) Negligible heat transfer from ends.

ANALYSIS: With $P = q_{\text{conv}}$, Newton's law of cooling yields

$$P = hA(T_s - T_\infty) = h\pi DL(T_s - T_\infty)$$

$$T_s = T_\infty + \frac{P}{h\pi DL}$$

In water,

$$T_s = 20^\circ\text{C} + \frac{2000\text{ W}}{5000\text{ W/m}^2\cdot\text{K} \times \pi \times 0.02\text{ m} \times 0.200\text{ m}}$$

$$T_s = 20^\circ\text{C} + 31.8^\circ\text{C} = 51.8^\circ\text{C}.$$

<

In air,

$$T_s = 20^\circ\text{C} + \frac{2000\text{ W}}{50\text{ W/m}^2\cdot\text{K} \times \pi \times 0.02\text{ m} \times 0.200\text{ m}}$$

$$T_s = 20^\circ\text{C} + 3183^\circ\text{C} = 3203^\circ\text{C}.$$

<

COMMENTS: (1) Air is much less effective than water as a heat transfer fluid. Hence, the cartridge temperature is much higher in air, so high, in fact, that the cartridge would melt. (2) In air, the high cartridge temperature would render radiation significant.

PROBLEM 1.17

KNOWN: Length, diameter and calibration of a hot wire anemometer. Temperature of air stream. Current, voltage drop and surface temperature of wire for a particular application.

FIND: Air velocity

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer from the wire by natural convection or radiation.

ANALYSIS: If all of the electric energy is transferred by convection to the air, the following equality must be satisfied

$$P_{\text{elec}} = EI = hA(T_s - T_\infty)$$

$$\text{where } A = \pi DL = \pi(0.0005\text{m} \times 0.02\text{m}) = 3.14 \times 10^{-5} \text{m}^2.$$

Hence,

$$h = \frac{EI}{A(T_s - T_\infty)} = \frac{5\text{V} \times 0.1\text{A}}{3.14 \times 10^{-5} \text{m}^2 (50^\circ\text{C})} = 318 \text{ W/m}^2 \cdot \text{K}$$

$$V = 6.25 \times 10^{-5} h^2 = 6.25 \times 10^{-5} (318 \text{ W/m}^2 \cdot \text{K})^2 = 6.3 \text{ m/s} \quad <$$

COMMENTS: The convection coefficient is sufficiently large to render buoyancy (natural convection) and radiation effects negligible.

PROBLEM 1.18

KNOWN: Chip width and maximum allowable temperature. Coolant conditions.

FIND: Maximum allowable chip power for air and liquid coolants.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer from sides and bottom, (3) Chip is at a uniform temperature (isothermal), (4) Negligible heat transfer by radiation in air.

ANALYSIS: All of the electrical power dissipated in the chip is transferred by convection to the coolant. Hence,

$$P = q$$

and from Newton's law of cooling,

$$P = hA(T - T_\infty) = hW^2(T - T_\infty).$$

In *air*,

$$P_{\text{max}} = 200\text{ W/m}^2\cdot\text{K}(0.005\text{ m})^2(85 - 15)^\circ\text{C} = 0.35\text{ W}. \quad <$$

In the *dielectric liquid*

$$P_{\text{max}} = 3000\text{ W/m}^2\cdot\text{K}(0.005\text{ m})^2(85 - 15)^\circ\text{C} = 5.25\text{ W}. \quad <$$

COMMENTS: Relative to liquids, air is a poor heat transfer fluid. Hence, in air the chip can dissipate far less energy than in the dielectric liquid.

PROBLEM 1.19

KNOWN: Length, diameter and maximum allowable surface temperature of a power transistor. Temperature and convection coefficient for air cooling.

FIND: Maximum allowable power dissipation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer through base of transistor, (3) Negligible heat transfer by radiation from surface of transistor.

ANALYSIS: Subject to the foregoing assumptions, the power dissipated by the transistor is equivalent to the rate at which heat is transferred by convection to the air. Hence,

$$P_{\text{elec}} = q_{\text{conv}} = hA(T_s - T_\infty)$$

$$\text{where } A = \pi \left(DL + D^2 / 4 \right) = \pi \left[0.012\text{m} \times 0.01\text{m} + (0.012\text{m})^2 / 4 \right] = 4.90 \times 10^{-4} \text{ m}^2.$$

For a maximum allowable surface temperature of 85°C , the power is

$$P_{\text{elec}} = 100 \text{ W/m}^2 \cdot \text{K} \left(4.90 \times 10^{-4} \text{ m}^2 \right) (85 - 25)^\circ\text{C} = 2.94 \text{ W} \quad <$$

COMMENTS: (1) For the prescribed surface temperature and convection coefficient, radiation will be negligible relative to convection. However, conduction through the base could be significant, thereby permitting operation at a larger power.

(2) The *local* convection coefficient varies over the surface, and *hot spots* could exist if there are locations at which the local value of h is substantially smaller than the prescribed average value.

PROBLEM 1.20

KNOWN: Air jet impingement is an effective means of cooling logic chips.

FIND: Procedure for measuring convection coefficients associated with a 10 mm × 10 mm chip.

SCHEMATIC:

ASSUMPTIONS: Steady-state conditions.

ANALYSIS: One approach would be to use the actual chip-substrate system, Case (a), to perform the measurements. In this case, the electric power dissipated in the chip would be transferred from the chip by radiation and conduction (to the substrate), as well as by convection to the jet. An energy balance for the chip yields $q_{elec} = q_{conv} + q_{cond} + q_{rad}$. Hence, with $q_{conv} = hA(T_s - T_\infty)$, where $A = 100 \text{ mm}^2$ is the surface area of the chip,

$$h = \frac{q_{elec} - q_{cond} - q_{rad}}{A(T_s - T_\infty)} \quad (1)$$

While the electric power (q_{elec}) and the jet (T_∞) and surface (T_s) temperatures may be measured, losses from the chip by conduction and radiation would have to be estimated. Unless the losses are negligible (an unlikely condition), the accuracy of the procedure could be compromised by uncertainties associated with determining the conduction and radiation losses.

A second approach, Case (b), could involve fabrication of a heater assembly for which the conduction and radiation losses are controlled and minimized. A 10 mm × 10 mm copper block ($k \sim 400 \text{ W/m}\cdot\text{K}$) could be inserted in a poorly conducting substrate ($k < 0.1 \text{ W/m}\cdot\text{K}$) and a patch heater could be applied to the back of the block and insulated from below. If conduction to both the substrate and insulation could thereby be rendered negligible, heat would be transferred almost exclusively through the block. If radiation were rendered negligible by applying a low emissivity coating ($\epsilon < 0.1$) to the surface of the copper block, virtually all of the heat would be transferred by convection to the jet. Hence, q_{cond} and q_{rad} may be neglected in equation (1), and the expression may be used to accurately determine h from the known (A) and measured (q_{elec} , T_s , T_∞) quantities.

COMMENTS: Since convection coefficients associated with gas flows are generally small, concurrent heat transfer by radiation and/or conduction must often be considered. However, jet impingement is one of the more effective means of transferring heat by convection and convection coefficients well in excess of $100 \text{ W/m}^2\cdot\text{K}$ may be achieved.

PROBLEM 1.21

KNOWN: Upper temperature set point, T_{set} , of a bimetallic switch and convection heat transfer coefficient between clothes dryer air and exposed surface of switch.

FIND: Electrical power for heater to maintain T_{set} when air temperature is $T_{\infty} = 50^{\circ}\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Electrical heater is perfectly insulated from dryer wall, (3) Heater and switch are isothermal at T_{set} , (4) Negligible heat transfer from sides of heater or switch, (5) Switch surface, A_s , loses heat only by convection.

ANALYSIS: Define a control volume around the bimetallic switch which experiences heat input from the heater and convection heat transfer to the dryer air. That is,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$q_{\text{elec}} - hA_s(T_{\text{set}} - T_{\infty}) = 0.$$

The electrical power required is,

$$q_{\text{elec}} = hA_s(T_{\text{set}} - T_{\infty})$$

$$q_{\text{elec}} = 25 \text{ W/m}^2 \cdot \text{K} \times 30 \times 10^{-6} \text{ m}^2 (70 - 50) \text{ K} = 15 \text{ mW}.$$

<

COMMENTS: (1) This type of controller can achieve variable operating air temperatures with a single set-point, inexpensive, bimetallic-thermostatic switch by adjusting power levels to the heater.

(2) Will the heater power requirement increase or decrease if the insulation pad is other than perfect?

PROBLEM 1.22

KNOWN: Hot vertical plate suspended in cool, still air. Change in plate temperature with time at the instant when the plate temperature is 225°C.

FIND: Convection heat transfer coefficient for this condition.

SCHEMATIC:

ASSUMPTIONS: (1) Plate is isothermal, (2) Negligible radiation exchange with surroundings, (3) Negligible heat lost through suspension wires.

ANALYSIS: As shown in the cooling curve above, the plate temperature decreases with time. The condition of interest is for time t_0 . For a control surface about the plate, the conservation of energy requirement is

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$$

$$-2hA_s(T_s - T_\infty) = Mc_p \frac{dT}{dt}$$

where A_s is the surface area of one side of the plate. Solving for h , find

$$h = \frac{Mc_p}{2A_s(T_s - T_\infty)} \left(\frac{-dT}{dt} \right)$$

$$h = \frac{3.75 \text{ kg} \times 2770 \text{ J/kg}\cdot\text{K}}{2 \times (0.3 \times 0.3) \text{ m}^2} \times 0.022 \text{ K/s} = 6.3 \text{ W/m}^2 \cdot \text{K} \quad <$$

COMMENTS: (1) Assuming the plate is very highly polished with emissivity of 0.08, determine whether radiation exchange with the surroundings at 25°C is negligible compared to convection.

(2) We will later consider the criterion for determining whether the isothermal plate assumption is reasonable. If the thermal conductivity of the present plate were high (such as aluminum or copper), the criterion would be satisfied.

PROBLEM 1.23

KNOWN: Width, input power and efficiency of a transmission. Temperature and convection coefficient associated with air flow over the casing.

FIND: Surface temperature of casing.

SCHEMATIC:

ASSUMPTIONS: (1) Steady state, (2) Uniform convection coefficient and surface temperature, (3) Negligible radiation.

ANALYSIS: From Newton's law of cooling,

$$q = hA_s (T_s - T_{\infty}) = 6hW^2 (T_s - T_{\infty})$$

where the output power is ηP_i and the heat rate is

$$q = P_i - P_o = P_i (1 - \eta) = 150 \text{ hp} \times 746 \text{ W / hp} \times 0.07 = 7833 \text{ W}$$

Hence,

$$T_s = T_{\infty} + \frac{q}{6 h W^2} = 30^{\circ}\text{C} + \frac{7833 \text{ W}}{6 \times 200 \text{ W / m}^2 \cdot \text{K} \times (0.3 \text{ m})^2} = 102.5^{\circ}\text{C} \quad <$$

COMMENTS: There will, in fact, be considerable variability of the local convection coefficient over the transmission case and the prescribed value represents an average over the surface.

PROBLEM 1.24

KNOWN: Air and wall temperatures of a room. Surface temperature, convection coefficient and emissivity of a person in the room.

FIND: Basis for difference in comfort level between summer and winter.

SCHEMATIC:

ASSUMPTIONS: (1) Person may be approximated as a small object in a large enclosure.

ANALYSIS: Thermal comfort is linked to heat loss from the human body, and a *chilled* feeling is associated with excessive heat loss. Because the temperature of the room air is fixed, the different summer and winter comfort levels cannot be attributed to convection heat transfer from the body. In both cases, the heat flux is

Summer and Winter: $q''_{\text{conv}} = h(T_s - T_{\infty}) = 2 \text{ W/m}^2 \cdot \text{K} \times 12^{\circ}\text{C} = 24 \text{ W/m}^2$

However, the heat flux due to radiation will differ, with values of

Summer: $q''_{\text{rad}} = \varepsilon\sigma(T_s^4 - T_{\text{sur}}^4) = 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (305^4 - 300^4) \text{ K}^4 = 28.3 \text{ W/m}^2$

Winter: $q''_{\text{rad}} = \varepsilon\sigma(T_s^4 - T_{\text{sur}}^4) = 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (305^4 - 287^4) \text{ K}^4 = 95.4 \text{ W/m}^2$

There is a significant difference between winter and summer radiation fluxes, and the chilled condition is attributable to the effect of the colder walls on radiation.

COMMENTS: For a representative surface area of $A = 1.5 \text{ m}^2$, the heat losses are $q_{\text{conv}} = 36 \text{ W}$, $q_{\text{rad}}(\text{summer}) = 42.5 \text{ W}$ and $q_{\text{rad}}(\text{winter}) = 143.1 \text{ W}$. The winter time radiation loss is significant and if maintained over a 24 h period would amount to 2,950 kcal.

PROBLEM 1.25

KNOWN: Diameter and emissivity of spherical interplanetary probe. Power dissipation within probe.

FIND: Probe surface temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation incident on the probe.

ANALYSIS: Conservation of energy dictates a balance between energy generation within the probe and radiation emission from the probe surface. Hence, at any instant

$$-\dot{E}_{\text{out}} + \dot{E}_g = 0$$

$$\varepsilon A_s \sigma T_s^4 = \dot{E}_g$$

$$T_s = \left(\frac{\dot{E}_g}{\varepsilon \pi D^2 \sigma} \right)^{1/4}$$

$$T_s = \left(\frac{150 \text{ W}}{0.8 \pi (0.5 \text{ m})^2 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4}$$

$$T_s = 254.7 \text{ K.}$$

<

COMMENTS: Incident radiation, as, for example, from the sun, would increase the surface temperature.

PROBLEM 1.26

KNOWN: Spherical shaped instrumentation package with prescribed surface emissivity within a large space-simulation chamber having walls at 77 K.

FIND: Acceptable power dissipation for operating the package surface temperature in the range $T_s = 40$ to 85°C . Show graphically the effect of emissivity variations for 0.2 and 0.3.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform surface temperature, (2) Chamber walls are large compared to the spherical package, and (3) Steady-state conditions.

ANALYSIS: From an overall energy balance on the package, the internal power dissipation P_e will be transferred by radiation exchange between the package and the chamber walls. From Eq. 1.7,

$$q_{rad} = P_e = \varepsilon A_s \sigma (T_s^4 - T_{sur}^4)$$

For the condition when $T_s = 40^\circ\text{C}$, with $A_s = \pi D^2$ the power dissipation will be

$$P_e = 0.25 \left(\pi \times 0.10^2 \text{ m}^2 \right) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times \left[(40 + 273)^4 - 77^4 \right] \text{ K}^4 = 4.3 \text{ W} \quad <$$

Repeating this calculation for the range $40 \leq T_s \leq 85^\circ\text{C}$, we can obtain the power dissipation as a function of surface temperature for the $\varepsilon = 0.25$ condition. Similarly, with 0.2 or 0.3, the family of curves shown below has been obtained.

COMMENTS: (1) As expected, the internal power dissipation increases with increasing emissivity and surface temperature. Because the radiation rate equation is non-linear with respect to temperature, the power dissipation will likewise not be linear with surface temperature.

(2) What is the maximum power dissipation that is possible if the surface temperature is not to exceed 85°C ? What kind of a coating should be applied to the instrument package in order to approach this limiting condition?

PROBLEM 1.27

KNOWN: Hot plate suspended in vacuum and surroundings temperature. Mass, specific heat, area and time rate of change of plate temperature.

FIND: (a) The emissivity of the plate, and (b) The rate at which radiation is emitted from the plate.

SCHEMATIC:

ASSUMPTIONS: (1) Plate is isothermal and at uniform temperature, (2) Large surroundings, (3) Negligible heat loss through suspension wires.

ANALYSIS: For a control volume about the plate, the conservation of energy requirement is

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st} \quad (1)$$

$$\text{where } \dot{E}_{st} = Mc_p \frac{dT}{dt} \quad (2)$$

$$\text{and for large surroundings } \dot{E}_{in} - \dot{E}_{out} = A\epsilon\sigma(T_{sur}^4 - T_s^4) \quad (3)$$

Combining Eqns. (1) through (3) yields

$$\epsilon = \frac{Mc_p \frac{dT}{dt}}{A\sigma (T_{sur}^4 - T_s^4)}$$

Noting that $T_{sur} = 25^\circ\text{C} + 273\text{ K} = 298\text{ K}$ and $T_s = 225^\circ\text{C} + 273\text{ K} = 498\text{ K}$, we find

$$\epsilon = \frac{3.75\text{ kg} \times 2770 \frac{\text{J}}{\text{kg}\cdot\text{K}} \times (-0.022 \frac{\text{K}}{\text{s}})}{2 \times 0.3\text{ m} \times 0.3\text{ m} \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} (498^4 - 298^4)\text{ K}^4} = 0.42 <$$

The rate at which radiation is emitted from the plate is

$$q_{rad,e} = \epsilon A \sigma T_s^4 = 0.42 \times 2 \times 0.3\text{ m} \times 0.3\text{ m} \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times (498\text{ K})^4 = 264\text{ W} <$$

COMMENTS: Note the importance of using kelvins when working with radiation heat transfer.

PROBLEM 1.28

KNOWN: Length, diameter, surface temperature and emissivity of steam line. Temperature and convection coefficient associated with ambient air. Efficiency and fuel cost for gas fired furnace.

FIND: (a) Rate of heat loss, (b) Annual cost of heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steam line operates continuously throughout year, (2) Net radiation transfer is between small surface (steam line) and large enclosure (plant walls).

ANALYSIS: (a) From Eqs. (1.3a) and (1.7), the heat loss is

$$q = q_{\text{conv}} + q_{\text{rad}} = A \left[h(T_s - T_{\infty}) + \varepsilon \sigma (T_s^4 - T_{\text{sur}}^4) \right]$$

where $A = \pi DL = \pi(0.1\text{m} \times 25\text{m}) = 7.85\text{m}^2$.

Hence,

$$q = 7.85\text{m}^2 \left[10\text{ W/m}^2 \cdot \text{K} (150 - 25)\text{K} + 0.8 \times 5.67 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4 (423^4 - 298^4)\text{K}^4 \right]$$

$$q = 7.85\text{m}^2 (1,250 + 1,095)\text{ W/m}^2 = (9813 + 8592)\text{ W} = 18,405\text{ W} \quad <$$

(b) The annual energy loss is

$$E = qt = 18,405\text{ W} \times 3600\text{ s/h} \times 24\text{h/d} \times 365\text{ d/y} = 5.80 \times 10^{11}\text{ J}$$

With a furnace energy consumption of $E_f = E/\eta_f = 6.45 \times 10^{11}\text{ J}$, the annual cost of the loss is

$$C = C_g E_f = 0.01\text{ \$/MJ} \times 6.45 \times 10^5\text{ MJ} = \$6450 \quad <$$

COMMENTS: The heat loss and related costs are unacceptable and should be reduced by insulating the steam line.

PROBLEM 1.29

KNOWN: Exact and approximate expressions for the linearized radiation coefficient, h_r and $h_{r,a}$, respectively.

FIND: (a) Comparison of the coefficients with $\varepsilon = 0.05$ and 0.9 and surface temperatures which may exceed that of the surroundings ($T_{\text{sur}} = 25^\circ\text{C}$) by 10 to 100°C ; also comparison with a free convection coefficient correlation, (b) Plot of the relative error $(h_r - h_{r,a})/h_r$ as a function of the furnace temperature associated with a workpiece at $T_s = 25^\circ\text{C}$ having $\varepsilon = 0.05, 0.2$ or 0.9 .

ASSUMPTIONS: (1) Furnace walls are large compared to the workpiece and (2) Steady-state conditions.

ANALYSIS: (a) The linearized radiation coefficient, Eq. 1.9, follows from the radiation exchange rate equation,

$$h_r = \varepsilon \sigma (T_s + T_{\text{sur}}) (T_s^2 + T_{\text{sur}}^2)$$

If $T_s \approx T_{\text{sur}}$, the coefficient may be approximated by the simpler expression

$$h_{r,a} = 4\varepsilon \sigma \bar{T}^3 \quad \bar{T} = (T_s + T_{\text{sur}})/2$$

For the condition of $\varepsilon = 0.05$, $T_s = T_{\text{sur}} + 10 = 35^\circ\text{C} = 308\text{ K}$ and $T_{\text{sur}} = 25^\circ\text{C} = 298\text{ K}$, find that

$$h_r = 0.05 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (308 + 298) (308^2 + 298^2) \text{ K}^3 = 0.32 \text{ W/m}^2 \cdot \text{K} <$$

$$h_{r,a} = 4 \times 0.05 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 ((308 + 298)/2)^3 \text{ K}^3 = 0.32 \text{ W/m}^2 \cdot \text{K} <$$

The free convection coefficient with $T_s = 35^\circ\text{C}$ and $T_\infty = T_{\text{sur}} = 25^\circ\text{C}$, find that

$$h = 0.98 \Delta T^{1/3} = 0.98 (T_s - T_\infty)^{1/3} = 0.98 (308 - 298)^{1/3} = 2.1 \text{ W/m}^2 \cdot \text{K} <$$

For the range $T_s - T_{\text{sur}} = 10$ to 100°C with $\varepsilon = 0.05$ and 0.9 , the results for the coefficients are tabulated below. For this range of surface and surroundings temperatures, the radiation and free convection coefficients are of comparable magnitude for moderate values of the emissivity, say $\varepsilon > 0.2$. The approximate expression for the linearized radiation coefficient is valid within 2% for these conditions.

(b) The above expressions for the radiation coefficients, h_r and $h_{r,a}$, are used for the workpiece at $T_s = 25^\circ\text{C}$ placed inside a furnace with walls which may vary from 100 to 1000°C . The relative error, $(h_r - h_{r,a})/h_r$, will be independent of the surface emissivity and is plotted as a function of T_{sur} . For $T_{\text{sur}} > 200^\circ\text{C}$, the approximate expression provides estimates which are in error more than 5%. The approximate expression should be used with caution, and only for surface and surrounding temperature differences of 50 to 100°C .

T_s ($^\circ\text{C}$)	ε	Coefficients ($\text{W/m}^2 \cdot \text{K}$)		
		h_r	$h_{r,a}$	h
35	0.05	0.32	0.32	2.1
	0.9	5.7	5.7	
135	0.05	0.51	0.50	4.7
	0.9	9.2	9.0	

PROBLEM 1.30

KNOWN: Chip width, temperature, and heat loss by convection in air. Chip emissivity and temperature of large surroundings.

FIND: Increase in chip power due to radiation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Radiation exchange between small surface and large enclosure.

ANALYSIS: Heat transfer from the chip due to net radiation exchange with the surroundings is

$$q_{\text{rad}} = \varepsilon W^2 \sigma (T^4 - T_{\text{sur}}^4)$$

$$q_{\text{rad}} = 0.9(0.005 \text{ m})^2 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (358^4 - 288^4) \text{ K}^4$$

$$q_{\text{rad}} = 0.0122 \text{ W.}$$

The percent increase in chip power is therefore

$$\frac{\Delta P}{P} \times 100 = \frac{q_{\text{rad}}}{q_{\text{conv}}} \times 100 = \frac{0.0122 \text{ W}}{0.350 \text{ W}} \times 100 = 3.5\%.$$

<

COMMENTS: For the prescribed conditions, radiation effects are small. Relative to convection, the effect of radiation would increase with increasing chip temperature and decreasing convection coefficient.

PROBLEM 1.31

KNOWN: Width, surface emissivity and maximum allowable temperature of an electronic chip. Temperature of air and surroundings. Convection coefficient.

FIND: (a) Maximum power dissipation for free convection with $h(\text{W/m}^2 \cdot \text{K}) = 4.2(T - T_\infty)^{1/4}$, (b) Maximum power dissipation for forced convection with $h = 250 \text{ W/m}^2 \cdot \text{K}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Radiation exchange between a small surface and a large enclosure, (3) Negligible heat transfer from sides of chip or from back of chip by conduction through the substrate.

ANALYSIS: Subject to the foregoing assumptions, electric power dissipation by the chip must be balanced by convection and radiation heat transfer from the chip. Hence, from Eq. (1.10),

$$P_{\text{elec}} = q_{\text{conv}} + q_{\text{rad}} = hA(T_s - T_\infty) + \varepsilon A \sigma (T_s^4 - T_{\text{sur}}^4)$$

where $A = L^2 = (0.015\text{m})^2 = 2.25 \times 10^{-4} \text{ m}^2$.

(a) If heat transfer is by natural convection,

$$q_{\text{conv}} = C A (T_s - T_\infty)^{5/4} = 4.2 \text{ W/m}^2 \cdot \text{K}^{5/4} \left(2.25 \times 10^{-4} \text{ m}^2 \right) (60\text{K})^{5/4} = 0.158 \text{ W}$$

$$q_{\text{rad}} = 0.60 \left(2.25 \times 10^{-4} \text{ m}^2 \right) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(358^4 - 298^4 \right) \text{K}^4 = 0.065 \text{ W}$$

$$P_{\text{elec}} = 0.158 \text{ W} + 0.065 \text{ W} = 0.223 \text{ W} \quad <$$

(b) If heat transfer is by forced convection,

$$q_{\text{conv}} = hA(T_s - T_\infty) = 250 \text{ W/m}^2 \cdot \text{K} \left(2.25 \times 10^{-4} \text{ m}^2 \right) (60\text{K}) = 3.375 \text{ W}$$

$$P_{\text{elec}} = 3.375 \text{ W} + 0.065 \text{ W} = 3.44 \text{ W} \quad <$$

COMMENTS: Clearly, radiation and natural convection are inefficient mechanisms for transferring heat from the chip. For $T_s = 85^\circ\text{C}$ and $T_\infty = 25^\circ\text{C}$, the natural convection coefficient is $11.7 \text{ W/m}^2 \cdot \text{K}$. Even for forced convection with $h = 250 \text{ W/m}^2 \cdot \text{K}$, the power dissipation is well below that associated with many of today's processors. To provide acceptable cooling, it is often necessary to attach the chip to a highly conducting substrate and to thereby provide an additional heat transfer mechanism due to conduction from the back surface.

PROBLEM 1.32

KNOWN: Vacuum enclosure maintained at 77 K by liquid nitrogen shroud while baseplate is maintained at 300 K by an electrical heater.

FIND: (a) Electrical power required to maintain baseplate, (b) Liquid nitrogen consumption rate, (c) Effect on consumption rate if aluminum foil ($\epsilon_p = 0.09$) is bonded to baseplate surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) No heat losses from backside of heater or sides of plate, (3) Vacuum enclosure large compared to baseplate, (4) Enclosure is evacuated with negligible convection, (5) Liquid nitrogen (LN2) is heated only by heat transfer to the shroud, and (6) Foil is intimately bonded to baseplate.

PROPERTIES: Heat of vaporization of liquid nitrogen (given): 125 kJ/kg.

ANALYSIS: (a) From an energy balance on the baseplate,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_{elec} - q_{rad} = 0$$

and using Eq. 1.7 for radiative exchange between the baseplate and shroud,

$$q_{elec} = \epsilon_p A_p \sigma (T_p^4 - T_{sh}^4).$$

Substituting numerical values, with $A_p = (\pi D_p^2 / 4)$, find

$$q_{elec} = 0.25 \left(\pi (0.3 \text{ m})^2 / 4 \right) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300^4 - 77^4) \text{ K}^4 = 8.1 \text{ W}. \quad <$$

(b) From an energy balance on the enclosure, radiative transfer heats the liquid nitrogen stream causing evaporation,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_{rad} - \dot{m}_{LN2} h_{fg} = 0$$

where \dot{m}_{LN2} is the liquid nitrogen consumption rate. Hence,

$$\dot{m}_{LN2} = q_{rad} / h_{fg} = 8.1 \text{ W} / 125 \text{ kJ/kg} = 6.48 \times 10^{-5} \text{ kg/s} = 0.23 \text{ kg/h}. \quad <$$

(c) If aluminum foil ($\epsilon_p = 0.09$) were bonded to the upper surface of the baseplate,

$$q_{rad, foil} = q_{rad} (\epsilon_f / \epsilon_p) = 8.1 \text{ W} (0.09 / 0.25) = 2.9 \text{ W}$$

and the liquid nitrogen consumption rate would be reduced by

$$(0.25 - 0.09) / 0.25 = 64\% \text{ to } 0.083 \text{ kg/h}. \quad <$$

PROBLEM 1.33

KNOWN: Width, input power and efficiency of a transmission. Temperature and convection coefficient for air flow over the casing. Emissivity of casing and temperature of surroundings.

FIND: Surface temperature of casing.

SCHEMATIC:

ASSUMPTIONS: (1) Steady state, (2) Uniform convection coefficient and surface temperature, (3) Radiation exchange with large surroundings.

ANALYSIS: Heat transfer from the case must balance heat dissipation in the transmission, which may be expressed as $q = P_i - P_o = P_i (1 - \eta) = 150 \text{ hp} \times 746 \text{ W/hp} \times 0.07 = 7833 \text{ W}$. Heat transfer from the case is by convection and radiation, in which case

$$q = A_s \left[h (T_s - T_\infty) + \varepsilon \sigma (T_s^4 - T_{\text{sur}}^4) \right]$$

where $A_s = 6 \text{ W}^2$. Hence,

$$7833 \text{ W} = 6(0.30 \text{ m})^2 \left[200 \text{ W/m}^2 \cdot \text{K} (T_s - 303 \text{ K}) + 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_s^4 - 303^4) \text{ K}^4 \right]$$

A trial-and-error solution yields

$$T_s \approx 373 \text{ K} = 100^\circ\text{C}$$

<

COMMENTS: (1) For $T_s \approx 373 \text{ K}$, $q_{\text{conv}} \approx 7,560 \text{ W}$ and $q_{\text{rad}} \approx 270 \text{ W}$, in which case heat transfer is dominated by convection, (2) If radiation is neglected, the corresponding surface temperature is $T_s = 102.5^\circ\text{C}$.

PROBLEM 1.34

KNOWN: Resistor connected to a battery operating at a prescribed temperature in air.

FIND: (a) Considering the resistor as the system, determine corresponding values for \dot{E}_{in} (W), \dot{E}_g (W), \dot{E}_{out} (W) and \dot{E}_{st} (W). If a control surface is placed about the entire system, determine the values for \dot{E}_{in} , \dot{E}_g , \dot{E}_{out} , and \dot{E}_{st} . (b) Determine the volumetric heat generation rate within the resistor, \dot{q} (W/m³), (c) Neglecting radiation from the resistor, determine the convection coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Electrical power is dissipated uniformly within the resistor, (2) Temperature of the resistor is uniform, (3) Negligible electrical power dissipated in the lead wires, (4) Negligible radiation exchange between the resistor and the surroundings, (5) No heat transfer occurs from the battery, (5) Steady-state conditions in the resistor.

ANALYSIS: (a) Referring to Section 1.3.1, the conservation of energy requirement for a control volume at an instant of time, Equation 1.11c, is

$$\dot{E}_{in} + \dot{E}_g - \dot{E}_{out} = \dot{E}_{st}$$

where \dot{E}_{in} , \dot{E}_{out} correspond to *surface* inflow and outflow processes, respectively. The energy generation term \dot{E}_g is associated with conversion of some other energy form (chemical, electrical, electromagnetic or nuclear) to thermal energy. The energy storage term \dot{E}_{st} is associated with changes in the internal, kinetic and/or potential energies of the matter in the control volume. \dot{E}_g , \dot{E}_{st} are *volumetric* phenomena. The electrical power delivered by the battery is $P = VI = 24V \times 6A = 144$ W.

Control volume: Resistor.

$$\begin{array}{ll} \dot{E}_{in} = 0 & \dot{E}_{out} = 144 \text{ W} \\ \dot{E}_g = 144 \text{ W} & \dot{E}_{st} = 0 \end{array} \quad \leftarrow$$

The \dot{E}_g term is due to conversion of electrical energy to thermal energy. The term \dot{E}_{out} is due to convection from the resistor surface to the air.

Continued...

PROBLEM 1.34 (Cont.)

Control volume: Battery-Resistor System.

$$\begin{array}{ll} \dot{E}_{in} = 0 & \dot{E}_{out} = 144 \text{ W} \\ \dot{E}_g = 144 \text{ W} & \dot{E}_{st} = 0 \end{array} <$$

Since we are considering conservation of thermal and mechanical energy, the conversion of chemical energy to electrical energy in the battery is irrelevant, and including the battery in the control volume doesn't change the thermal and mechanical energy terms

(b) From the energy balance on the resistor with volume, $\forall = (\pi D^2/4)L$,

$$\dot{E}_g = \dot{q}\forall \quad 144 \text{ W} = \dot{q} \left(\pi (0.06 \text{ m})^2 / 4 \times 0.25 \text{ m} \right) \quad \dot{q} = 2.04 \times 10^5 \text{ W/m}^3 <$$

(c) From the energy balance on the resistor and Newton's law of cooling with $A_s = \pi DL + 2(\pi D^2/4)$,

$$\dot{E}_t = \dot{q}_{cv} = hA_s (T_s - T_\infty)$$

$$144 \text{ W} = h \left[\pi \times 0.06 \text{ m} \times 0.25 \text{ m} + 2 \left(\pi \times (0.06 \text{ m})^2 / 4 \right) \right] (95 - 25)^\circ \text{C}$$

$$144 \text{ W} = h [0.0471 + 0.0057] \text{ m}^2 (95 - 25)^\circ \text{C}$$

$$h = 39.0 \text{ W/m}^2 \cdot \text{K} <$$

COMMENTS: (1) In using the conservation of energy requirement, Equation 1.11c, it is important to recognize that \dot{E}_{in} and \dot{E}_{out} will always represent *surface* processes and \dot{E}_g and \dot{E}_{st} , *volumetric* processes. The generation term \dot{E}_g is associated with a *conversion* process from some form of energy to *thermal energy*. The storage term \dot{E}_{st} represents the rate of change of *internal kinetic, and potential energy*.

(2) From Table 1.1 and the magnitude of the convection coefficient determined from part (c), we conclude that the resistor is experiencing forced, rather than free, convection.

PROBLEM 1.35

KNOWN: Thickness and initial temperature of an aluminum plate whose thermal environment is changed.

FIND: (a) Initial rate of temperature change, (b) Steady-state temperature of plate, (c) Effect of emissivity and absorptivity on steady-state temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible end effects, (2) Uniform plate temperature at any instant, (3) Constant properties, (4) Adiabatic bottom surface, (5) Negligible radiation from surroundings, (6) No internal heat generation.

ANALYSIS: (a) Applying an energy balance, Eq. 1.11c, at an instant of time to a control volume about the plate, $\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$, it follows for a unit surface area.

$$\alpha_S G_S (1 \text{ m}^2) - E (1 \text{ m}^2) - q''_{conv} (1 \text{ m}^2) = (d/dt)(McT) = \rho (1 \text{ m}^2 \times L) c (dT/dt).$$

Rearranging and substituting from Eqs. 1.3 and 1.5, we obtain

$$dT/dt = (1/\rho Lc) [\alpha_S G_S - \epsilon \sigma T_i^4 - h(T_i - T_\infty)].$$

$$dT/dt = \left(2700 \text{ kg/m}^3 \times 0.004 \text{ m} \times 900 \text{ J/kg} \cdot \text{K} \right)^{-1} \times \left[0.8 \times 900 \text{ W/m}^2 - 0.25 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298 \text{ K})^4 - 20 \text{ W/m}^2 \cdot \text{K} (25 - 20)^\circ \text{C} \right]$$

$$dT/dt = 0.052^\circ \text{C/s}.$$

(b) Under steady-state conditions, $\dot{E}_{st} = 0$, and the energy balance reduces to

$$\alpha_S G_S = \epsilon \sigma T^4 + h(T - T_\infty) \quad (2)$$

$$0.8 \times 900 \text{ W/m}^2 = 0.25 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times T^4 + 20 \text{ W/m}^2 \cdot \text{K} (T - 293 \text{ K})$$

The solution yields $T = 321.4 \text{ K} = 48.4^\circ \text{C}$.

(c) Using the IHT *First Law Model* for an *Isothermal Plane Wall*, parametric calculations yield the following results.

COMMENTS: The surface radiative properties have a significant effect on the plate temperature, which decreases with increasing ϵ and decreasing α_S . If a low temperature is desired, the plate coating should be characterized by a large value of ϵ/α_S . The temperature also decreases with increasing h .

PROBLEM 1.36

KNOWN: Blood inlet and outlet temperatures and flow rate. Dimensions of tubing.

FIND: Required rate of heat addition and estimate of kinetic and potential energy changes.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible liquid with negligible kinetic and potential energy changes, (3) Blood has properties of water.

PROPERTIES: Table A.6, Water ($\bar{T} \approx 300 \text{ K}$): $c_{p,f} = 4179 \text{ J/kg} \cdot \text{K}$, $\rho_f = 1/v_f = 997 \text{ kg/m}^3$.

ANALYSIS: From an overall energy balance, Equation 1.11e,

$$q = \dot{m}c_p(T_{out} - T_{in})$$

where

$$\dot{m} = \rho_f \dot{V} = 997 \text{ kg/m}^3 \times 200 \text{ ml/min} \times 10^{-6} \text{ m}^3/\text{ml} / 60 \text{ s/min} = 3.32 \times 10^{-3} \text{ kg/s}$$

Thus

$$q = 3.32 \times 10^{-3} \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} \times (37^\circ\text{C} - 10^\circ\text{C}) = 375 \text{ W} \quad <$$

The velocity in the tube is given by

$$V = \dot{V}/A_c = 200 \text{ ml/min} \times 10^{-6} \text{ m}^3/\text{ml} / (60 \text{ s/min} \times 6.4 \times 10^{-3} \text{ m} \times 1.6 \times 10^{-3} \text{ m}) = 0.33 \text{ m/s}$$

The change in kinetic energy is

$$\dot{m}\left(\frac{1}{2}V^2 - 0\right) = 3.32 \times 10^{-3} \text{ kg/s} \times \frac{1}{2} \times (0.33 \text{ m/s})^2 = 1.8 \times 10^{-4} \text{ W} \quad <$$

The change in potential energy is

$$\dot{m}gz = 3.32 \times 10^{-3} \text{ kg/s} \times 9.8 \text{ m/s}^2 \times 2 \text{ m} = 0.065 \text{ W} \quad <$$

COMMENT: The kinetic and potential energy changes are both negligible relative to the thermal energy change.

PROBLEM 1.37

KNOWN: Daily hot water consumption for a family of four and temperatures associated with ground water and water storage tank. Unit cost of electric power. Heat pump COP.

FIND: Annual heating requirement and costs associated with using electric resistance heating or a heat pump.

SCHEMATIC:

ASSUMPTIONS: (1) Process may be modelled as one involving heat addition in a closed system, (2) Properties of water are constant.

PROPERTIES: Table A-6, Water ($T_{\text{avg}} = 308 \text{ K}$): $\rho = v_f^{-1} = 993 \text{ kg/m}^3$, $c_{p,f} = 4.178 \text{ kJ/kg}\cdot\text{K}$.

ANALYSIS: From Eq. 1.11a, the daily heating requirement is $Q_{\text{daily}} = \Delta U_t = Mc\Delta T = \rho Vc(T_f - T_i)$. With $V = 100 \text{ gal}/264.17 \text{ gal/m}^3 = 0.379 \text{ m}^3$,

$$Q_{\text{daily}} = 993 \text{ kg/m}^3 (0.379 \text{ m}^3) 4.178 \text{ kJ/kg}\cdot\text{K} (40^\circ\text{C}) = 62,900 \text{ kJ}$$

The annual heating requirement is then, $Q_{\text{annual}} = 365 \text{ days} (62,900 \text{ kJ/day}) = 2.30 \times 10^7 \text{ kJ}$, or, with $1 \text{ kWh} = 1 \text{ kJ/s} (3600 \text{ s}) = 3600 \text{ kJ}$,

$$Q_{\text{annual}} = 6380 \text{ kWh} \quad <$$

With electric resistance heating, $Q_{\text{annual}} = Q_{\text{elec}}$ and the associated cost, C , is

$$C = 6380 \text{ kWh} (\$0.08/\text{kWh}) = \$510 \quad <$$

If a heat pump is used, $Q_{\text{annual}} = \text{COP}(W_{\text{elec}})$. Hence,

$$W_{\text{elec}} = Q_{\text{annual}}/(\text{COP}) = 6380 \text{ kWh}/(3) = 2130 \text{ kWh}$$

The corresponding cost is

$$C = 2130 \text{ kWh} (\$0.08/\text{kWh}) = \$170 \quad <$$

COMMENTS: Although annual operating costs are significantly lower for a heat pump, corresponding capital costs are much higher. The feasibility of this approach depends on other factors such as geography and seasonal variations in COP, as well as the time value of money.

PROBLEM 1.38

KNOWN: Initial temperature of water and tank volume. Power dissipation, emissivity, length and diameter of submerged heaters. Expressions for convection coefficient associated with natural convection in water and air.

FIND: (a) Time to raise temperature of water to prescribed value, (b) Heater temperature shortly after activation and at conclusion of process, (c) Heater temperature if activated in air.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss from tank to surroundings, (2) Water is *well-mixed* (at a uniform, but time varying temperature) during heating, (3) Negligible changes in thermal energy storage for heaters, (4) Constant properties, (5) Surroundings afforded by tank wall are large relative to heaters.

ANALYSIS: (a) Application of conservation of energy to a closed system (the water) at an instant, Equation (1.11c), with

$$\dot{E}_{st} = dU_t/dt, \quad \dot{E}_{in} = 3q_1, \quad \dot{E}_{out} = 0, \quad \text{and} \quad \dot{E}_g = 0,$$

$$\text{yields } \frac{dU_t}{dt} = 3q_1 \quad \text{and} \quad \rho V c \frac{dT}{dt} = 3q_1$$

$$\text{Hence, } \int_0^t dt = (\rho V c / 3q_1) \int_{T_i}^{T_f} dT$$

$$t = \frac{990 \text{ kg/m}^3 \times 10 \text{ gal} \left(3.79 \times 10^{-3} \text{ m}^3 / \text{gal} \right) 4180 \text{ J/kg} \cdot \text{K}}{3 \times 500 \text{ W}} (335 - 295) \text{ K} = 4180 \text{ s} \quad <$$

(b) From Equation (1.3a), the heat rate by convection from each heater is

$$q_1 = Aq_1'' = Ah(T_s - T) = (\pi DL) 370(T_s - T)^{4/3}$$

$$\text{Hence, } T_s = T + \left(\frac{q_1}{370\pi DL} \right)^{3/4} = T + \left(\frac{500 \text{ W}}{370 \text{ W/m}^2 \cdot \text{K}^{4/3} \times \pi \times 0.025 \text{ m} \times 0.250 \text{ m}} \right)^{3/4} = (T + 24) \text{ K}$$

With water temperatures of $T_i \approx 295 \text{ K}$ and $T_f = 335 \text{ K}$ shortly after the start of heating and at the end of heating, respectively, $T_{s,i} = 319 \text{ K}$ and $T_{s,f} = 359 \text{ K}$ <

(c) From Equation (1.10), the heat rate in air is

$$q_1 = \pi DL \left[0.70(T_s - T_\infty)^{4/3} + \varepsilon \sigma (T_s^4 - T_{sur}^4) \right]$$

Substituting the prescribed values of q_1 , D , L , $T_\infty = T_{sur}$ and ε , an iterative solution yields

$$T_s = 830 \text{ K} \quad <$$

COMMENTS: In part (c) it is presumed that the heater can be operated at $T_s = 830 \text{ K}$ without experiencing burnout. The much larger value of T_s for air is due to the smaller convection coefficient. However, with q_{conv} and q_{rad} equal to 59 W and 441 W, respectively, a significant portion of the heat dissipation is effected by radiation.

PROBLEM 1.39

KNOWN: Power consumption, diameter, and inlet and discharge temperatures of a hair dryer.

FIND: (a) Volumetric flow rate and discharge velocity of heated air, (b) Heat loss from case.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant air properties, (3) Negligible potential and kinetic energy changes of air flow, (4) Negligible work done by fan, (5) Negligible heat transfer from casing of dryer to ambient air (Part (a)), (6) Radiation exchange between a small surface and a large enclosure (Part (b)).

ANALYSIS: (a) For a control surface about the air flow passage through the dryer, conservation of energy for an open system reduces to

$$\dot{m}(u + pv)_i - \dot{m}(u + pv)_o + q = 0$$

where $u + pv = i$ and $q = P_{\text{elec}}$. Hence, with $\dot{m}(i_i - i_o) = \dot{m}c_p(T_i - T_o)$,

$$\dot{m}c_p(T_o - T_i) = P_{\text{elec}}$$

$$\dot{m} = \frac{P_{\text{elec}}}{c_p(T_o - T_i)} = \frac{500 \text{ W}}{1007 \text{ J/kg} \cdot \text{K}(25^\circ\text{C})} = 0.0199 \text{ kg/s}$$

$$\dot{V} = \frac{\dot{m}}{\rho} = \frac{0.0199 \text{ kg/s}}{1.10 \text{ kg/m}^3} = 0.0181 \text{ m}^3/\text{s} \quad <$$

$$V_o = \frac{\dot{V}}{A_c} = \frac{4\dot{V}}{\pi D^2} = \frac{4 \times 0.0181 \text{ m}^3/\text{s}}{\pi(0.07 \text{ m})^2} = 4.7 \text{ m/s} \quad <$$

(b) Heat transfer from the casing is by convection and radiation, and from Equation (1.10)

$$q = hA_s(T_s - T_\infty) + \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4)$$

where $A_s = \pi DL = \pi(0.07 \text{ m} \times 0.15 \text{ m}) = 0.033 \text{ m}^2$. Hence,

$$q = 4 \text{ W/m}^2 \cdot \text{K}(0.033 \text{ m}^2)(20^\circ\text{C}) + 0.8 \times 0.033 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4(313^4 - 293^4) \text{ K}^4$$

$$q = 2.64 \text{ W} + 3.33 \text{ W} = 5.97 \text{ W} \quad <$$

The heat loss is much less than the electrical power, and the assumption of negligible heat loss is justified.

COMMENTS: Although the mass flow rate is invariant, the volumetric flow rate increases because the air is heated in its passage through the dryer, causing a reduction in the density. However, for the prescribed temperature rise, the change in ρ , and hence the effect on \dot{V} , is small.

PROBLEM 1.40

KNOWN: Speed, width, thickness and initial and final temperatures of 304 stainless steel in an annealing process. Dimensions of annealing oven and temperature, emissivity and convection coefficient of surfaces exposed to ambient air and large surroundings of equivalent temperatures. Thickness of pad on which oven rests and pad surface temperatures.

FIND: Oven operating power.

SCHEMATIC:

ASSUMPTIONS: (1) steady-state, (2) Constant properties, (3) Negligible changes in kinetic and potential energy.

PROPERTIES: Table A.1, St.St.304 ($\bar{T} = (T_i + T_o)/2 = 775 \text{ K}$): $\rho = 7900 \text{ kg/m}^3$, $c_p = 578 \text{ J/kg}\cdot\text{K}$;
Table A.3, Concrete, $T = 300 \text{ K}$: $k_c = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: The rate of energy addition to the oven must balance the rate of energy transfer to the steel sheet and the rate of heat loss from the oven. Viewing the oven as an open system, Equation (1.11e) yields

$$P_{\text{elec}} - q = \dot{m}c_p(T_o - T_i)$$

where q is the heat transferred from the oven. With $\dot{m} = \rho V_s (W_s t_s)$ and

$$q = (2H_o L_o + 2H_o W_o + W_o L_o) \times \left[h(T_s - T_\infty) + \varepsilon_s \sigma (T_s^4 - T_{\text{sur}}^4) \right] + k_c (W_o L_o) (T_s - T_b) / t_c,$$

it follows that

$$P_{\text{elec}} = \rho V_s (W_s t_s) c_p (T_o - T_i) + (2H_o L_o + 2H_o W_o + W_o L_o) \times \left[h(T_s - T_\infty) + \varepsilon_s \sigma (T_s^4 - T_{\text{sur}}^4) \right] + k_c (W_o L_o) (T_s - T_b) / t_c$$

$$P_{\text{elec}} = 7900 \text{ kg/m}^3 \times 0.01 \text{ m/s} (2 \text{ m} \times 0.008 \text{ m}) 578 \text{ J/kg}\cdot\text{K} (1250 - 300) \text{ K} \\ + (2 \times 2 \text{ m} \times 25 \text{ m} + 2 \times 2 \text{ m} \times 2.4 \text{ m} + 2.4 \text{ m} \times 25 \text{ m}) [10 \text{ W/m}^2 \cdot \text{K} (350 - 300) \text{ K} \\ + 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (350^4 - 300^4) \text{ K}^4] + 1.4 \text{ W/m}\cdot\text{K} (2.4 \text{ m} \times 25 \text{ m}) (350 - 300) \text{ K} / 0.5 \text{ m}$$

$$P_{\text{elec}} = 694,000 \text{ W} + 169.6 \text{ m}^2 (500 + 313) \text{ W/m}^2 + 8400 \text{ W} \\ = (694,000 + 84,800 + 53,100 + 8400) \text{ W} = 840 \text{ kW}$$

COMMENTS: Of the total energy input, 83% is transferred to the steel while approximately 10%, 6% and 1% are lost by convection, radiation and conduction from the oven. The convection and radiation losses can both be reduced by adding insulation to the side and top surfaces, which would reduce the corresponding value of T_s .

PROBLEM 1.41

KNOWN: Hot plate-type wafer thermal processing tool based upon heat transfer modes by conduction through gas within the gap and by radiation exchange across gap.

FIND: (a) Radiative and conduction heat fluxes across gap for specified hot plate and wafer temperatures and gap separation; initial time rate of change in wafer temperature for each mode, and (b) heat fluxes and initial temperature-time change for gap separations of 0.2, 0.5 and 1.0 mm for hot plate temperatures $300 < T_h < 1300^\circ\text{C}$. Comment on the relative importance of the modes and the influence of the gap distance. Under what conditions could a wafer be heated to 900°C in less than 10 seconds?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions for flux calculations, (2) Diameter of hot plate and wafer much larger than gap spacing, approximating plane, infinite planes, (3) One-dimensional conduction through gas, (4) Hot plate and wafer are blackbodies, (5) Negligible heat losses from wafer backside, and (6) Wafer temperature is uniform at the onset of heating.

PROPERTIES: Wafer: $\rho = 2700 \text{ kg/m}^3$, $c = 875 \text{ J/kg}\cdot\text{K}$; Gas in gap: $k = 0.0436 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) The radiative heat flux between the hot plate and wafer for $T_h = 600^\circ\text{C}$ and $T_w = 20^\circ\text{C}$ follows from the rate equation,

$$q''_{\text{rad}} = \sigma (T_h^4 - T_w^4) = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left((600 + 273)^4 - (20 + 273)^4 \right) \text{ K}^4 = 32.5 \text{ kW/m}^2 <$$

The conduction heat flux through the gas in the gap with $L = 0.2 \text{ mm}$ follows from Fourier's law,

$$q''_{\text{cond}} = k \frac{T_h - T_w}{L} = 0.0436 \text{ W/m}\cdot\text{K} \frac{(600 - 20) \text{ K}}{0.0002 \text{ m}} = 126 \text{ kW/m}^2 <$$

The initial time rate of change of the wafer can be determined from an energy balance on the wafer at the instant of time the heating process begins,

$$\dot{E}''_{\text{in}} - \dot{E}''_{\text{out}} = \dot{E}''_{\text{st}} \quad \dot{E}''_{\text{st}} = \rho c d \left(\frac{dT_w}{dt} \right)_i$$

where $\dot{E}''_{\text{out}} = 0$ and $\dot{E}''_{\text{in}} = q''_{\text{rad}}$ or q''_{cond} . Substituting numerical values, find

$$\left(\frac{dT_w}{dt} \right)_{i,\text{rad}} = \frac{q''_{\text{rad}}}{\rho c d} = \frac{32.5 \times 10^3 \text{ W/m}^2}{2700 \text{ kg/m}^3 \times 875 \text{ J/kg}\cdot\text{K} \times 0.00078 \text{ m}} = 17.6 \text{ K/s} <$$

$$\left(\frac{dT_w}{dt} \right)_{i,\text{cond}} = \frac{q''_{\text{cond}}}{\rho c d} = 68.6 \text{ K/s} <$$

Continued

PROBLEM 1.41 (Cont.)

(b) Using the foregoing equations, the heat fluxes and initial rate of temperature change for each mode can be calculated for selected gap separations L and range of hot plate temperatures T_h with $T_w = 20^\circ\text{C}$.

In the left-hand graph, the conduction heat flux increases linearly with T_h and inversely with L as expected. The radiative heat flux is independent of L and highly non-linear with T_h , but does not approach that for the highest conduction heat rate until T_h approaches 1200°C .

The general trends for the initial temperature-time change, $(dT_w/dt)_i$, follow those for the heat fluxes. To reach 900°C in 10 s requires an average temperature-time change rate of 90 K/s . Recognizing that (dT_w/dt) will decrease with increasing T_w , this rate could be met only with a very high T_h and the smallest L .

PROBLEM 1.42

KNOWN: Silicon wafer, radiantly heated by lamps, experiencing an annealing process with known backside temperature.

FIND: Whether temperature difference across the wafer thickness is less than 2°C in order to avoid damaging the wafer.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in wafer, (3) Radiation exchange between upper surface of wafer and surroundings is between a small object and a large enclosure, and (4) Vacuum condition in chamber, no convection.

PROPERTIES: Wafer: $k = 30 \text{ W/m}\cdot\text{K}$, $\varepsilon = \alpha_\ell = 0.65$.

ANALYSIS: Perform a surface energy balance on the upper surface of the wafer to determine $T_{w,u}$. The processes include the absorbed radiant flux from the lamps, radiation exchange with the chamber walls, and conduction through the wafer.

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' = 0$$

$$\alpha_\ell q''_s - q''_{\text{rad}} - q''_{\text{cd}} = 0$$

$$\alpha_\ell q''_s - \varepsilon \sigma (T_{w,u}^4 - T_{\text{sur}}^4) - k \frac{T_{w,u} - T_{w,l}}{L} = 0$$

$$0.65 \times 3.0 \times 10^5 \text{ W/m}^2 - 0.65 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(T_{w,u}^4 - (27 + 273)^4 \right) - 30 \text{ W/m}\cdot\text{K} \left[T_{w,u} - (997 + 273) \right] \text{ K} / 0.00078 \text{ m} = 0$$

$$T_{w,u} = 1273 \text{ K} = 1000^\circ\text{C}$$

<

COMMENTS: (1) The temperature difference for this steady-state operating condition, $T_{w,u} - T_{w,l}$, is larger than 2°C. Warping of the wafer and inducing slip planes in the crystal structure could occur.

(2) The radiation exchange rate equation requires that temperature must be expressed in kelvin units. Why is it permissible to use kelvin or Celsius temperature units in the conduction rate equation?

(3) Note how the surface energy balance, Eq. 1.12, is represented schematically. It is essential to show the control surfaces, and then identify the rate processes associated with the surfaces. Make sure the directions (in or out) of the process are consistent with the energy balance equation.

PROBLEM 1.43

KNOWN: Silicon wafer positioned in furnace with top and bottom surfaces exposed to hot and cool zones, respectively.

FIND: (a) Initial rate of change of the wafer temperature corresponding to the wafer temperature $T_{w,i} = 300 \text{ K}$, and (b) Steady-state temperature reached if the wafer remains in this position. How significant is convection for this situation? Sketch how you'd expect the wafer temperature to vary as a function of vertical distance.

SCHEMATIC:

ASSUMPTIONS: (1) Wafer temperature is uniform, (2) Transient conditions when wafer is initially positioned, (3) Hot and cool zones have uniform temperatures, (3) Radiation exchange is between small surface (wafer) and large enclosure (chamber, hot or cold zone), and (4) Negligible heat losses from wafer to mounting pin holder.

ANALYSIS: The energy balance on the wafer illustrated in the schematic above includes convection from the upper (u) and lower (l) surfaces with the ambient gas, radiation exchange with the hot- and cool-zone (chamber) surroundings, and the rate of energy storage term for the transient condition.

$$\dot{E}_{in}'' - \dot{E}_{out}'' = \dot{E}_{st}''$$

$$q''_{rad,h} + q''_{rad,c} - q''_{conv,u} - q''_{conv,l} = \rho c d \frac{dT_w}{dt}$$

$$\epsilon \sigma (T_{sur,h}^4 - T_w^4) + \epsilon \sigma (T_{sur,c}^4 - T_w^4) - h_u (T_w - T_\infty) - h_l (T_w - T_\infty) = \rho c d \frac{dT_w}{dt}$$

(a) For the initial condition, the time rate of temperature change of the wafer is determined using the energy balance above with $T_w = T_{w,i} = 300 \text{ K}$,

$$0.65 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1500^4 - 300^4) \text{ K}^4 + 0.65 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (330^4 - 300^4) \text{ K}^4$$

$$-8 \text{ W/m}^2 \cdot \text{K} (300 - 700) \text{ K} - 4 \text{ W/m}^2 \cdot \text{K} (300 - 700) \text{ K} =$$

$$2700 \text{ kg/m}^3 \times 875 \text{ J/kg} \cdot \text{K} \times 0.00078 \text{ m} (dT_w/dt)_i$$

$$(dT_w/dt)_i = 104 \text{ K/s}$$

<

(b) For the steady-state condition, the energy storage term is zero, and the energy balance can be solved for the steady-state wafer temperature, $T_w = T_{w,ss}$.

Continued

PROBLEM 1.43 (Cont.)

$$0.65\sigma(1500^4 - T_{w,ss}^4)K^4 + 0.65\sigma(330^4 - T_{w,ss}^4)K^4$$

$$-8W/m^2 \cdot K(T_{w,ss} - 700)K - 4W/m^2 \cdot K(T_{w,ss} - 700)K = 0$$

$$T_{w,ss} = 1251 \text{ K}$$

<

To determine the relative importance of the convection processes, re-solve the energy balance above ignoring those processes to find $(dT_w/dt)_i = 101 \text{ K/s}$ and $T_{w,ss} = 1262 \text{ K}$. We conclude that the radiation exchange processes control the initial time rate of temperature change and the steady-state temperature.

If the wafer were elevated above the present operating position, its temperature would increase, since the lower surface would begin to experience radiant exchange with progressively more of the hot zone chamber. Conversely, by lowering the wafer, the upper surface would experience less radiant exchange with the hot zone chamber, and its temperature would decrease. The temperature-distance trend might appear as shown in the sketch.

PROBLEM 1.44

KNOWN: Radial distribution of heat dissipation in a cylindrical container of radioactive wastes. Surface convection conditions.

FIND: Total energy generation rate and surface temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible temperature drop across thin container wall.

ANALYSIS: The rate of energy generation is

$$\begin{aligned}\dot{E}_g &= \int \dot{q} dV = \dot{q}_o \int_0^{r_o} \left[1 - (r/r_o)^2 \right] 2\pi r L dr \\ \dot{E}_g &= 2\pi L \dot{q}_o \left(r_o^2/2 - r_o^2/4 \right)\end{aligned}$$

or per unit length,

$$\dot{E}'_g = \frac{\pi \dot{q}_o r_o^2}{2}.$$

Performing an energy balance for a control surface about the container yields, at an instant,

$$\dot{E}'_g - \dot{E}'_{out} = 0$$

and substituting for the convection heat rate per unit length,

$$\frac{\pi \dot{q}_o r_o^2}{2} = h(2\pi r_o)(T_s - T_\infty)$$

$$T_s = T_\infty + \frac{\dot{q}_o r_o}{4h}.$$

COMMENTS: The temperature within the radioactive wastes increases with decreasing r from T_s at r_o to a maximum value at the centerline.

PROBLEM 1.45

KNOWN: Rod of prescribed diameter experiencing electrical dissipation from passage of electrical current and convection under different air velocity conditions. See Example 1.3.

FIND: Rod temperature as a function of the electrical current for $0 \leq I \leq 10$ A with convection coefficients of 50, 100 and $250 \text{ W/m}^2 \cdot \text{K}$. Will variations in the surface emissivity have a significant effect on the rod temperature?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform rod temperature, (3) Radiation exchange between the outer surface of the rod and the surroundings is between a small surface and large enclosure.

ANALYSIS: The energy balance on the rod for steady-state conditions has the form,

$$q'_{\text{conv}} + q'_{\text{rad}} = \dot{E}'_{\text{gen}}$$

$$\pi D h (T - T_{\infty}) + \pi D \varepsilon \sigma (T^4 - T_{\text{sur}}^4) = I^2 R'_e$$

Using this equation in the Workspace of IHT, the rod temperature is calculated and plotted as a function of current for selected convection coefficients.

COMMENTS: (1) For forced convection over the cylinder, the convection heat transfer coefficient is dependent upon air velocity approximately as $h \sim V^{0.6}$. Hence, to achieve a 5-fold change in the convection coefficient (from 50 to $250 \text{ W/m}^2 \cdot \text{K}$), the air velocity must be changed by a factor of nearly 15.

Continued

PROBLEM 1.45 (Cont.)

(2) For the condition of $I = 4 \text{ A}$ with $h = 50 \text{ W/m}^2 \cdot \text{K}$ with $T = 63.5^\circ\text{C}$, the convection and radiation exchange rates per unit length are, respectively, $q'_{\text{conv}} = 5.7 \text{ W/m}$ and $q'_{\text{rad}} = 0.67 \text{ W/m}$. We conclude that convection is the dominant heat transfer mode and that changes in surface emissivity could have only a minor effect. Will this also be the case if $h = 100$ or $250 \text{ W/m}^2 \cdot \text{K}$?

(3) What would happen to the rod temperature if there was a “loss of coolant” condition where the air flow would cease?

(4) The Workspace for the IHT program to calculate the heat losses and perform the parametric analysis to generate the graph is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results. It is also good practice to show plots in *customary* units, that is, the units used to prescribe the problem. As such the graph of the rod temperature is shown above with Celsius units, even though the calculations require temperatures in kelvins.

PROBLEM 1.46

KNOWN: Long bus bar of prescribed diameter and ambient air and surroundings temperatures. Relations for the electrical resistivity and free convection coefficient as a function of temperature.

FIND: (a) Current carrying capacity of the bus bar if its surface temperature is not to exceed 65°C; compare relative importance of convection and radiation exchange heat rates, and (b) Show graphically the operating temperature of the bus bar as a function of current for the range $100 \leq I \leq 5000$ A for bus-bar diameters of 10, 20 and 40 mm. Plot the ratio of the heat transfer by convection to the total heat transfer for these conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Bus bar and conduit are very long, (3) Uniform bus-bar temperature, (4) Radiation exchange between the outer surface of the bus bar and the conduit is between a small surface and a large enclosure.

PROPERTIES: Bus-bar material, $\rho_e = \rho_{e,o} [1 + \alpha(T - T_o)]$, $\rho_{e,o} = 0.0171 \mu\Omega \cdot m$, $T_o = 25^\circ\text{C}$, $\alpha = 0.00396 \text{ K}^{-1}$.

ANALYSIS: An energy balance on the bus-bar for a unit length as shown in the schematic above has the form

$$\begin{aligned} \dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_{gen} &= 0 \\ -q'_{rad} - q'_{conv} + I^2 R'_e &= 0 \\ -\varepsilon \pi D \sigma (T^4 - T_{sur}^4) - h \pi D (T - T_\infty) + I^2 \rho_e / A_c &= 0 \end{aligned}$$

where $R'_e = \rho_e / A_c$ and $A_c = \pi D^2 / 4$. Using the relations for $\rho_e(T)$ and $h(T,D)$, and substituting numerical values with $T = 65^\circ\text{C}$, find

$$q'_{rad} = 0.85 \pi (0.020 \text{ m}) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left([65 + 273]^4 - [30 + 273]^4 \right) \text{ K}^4 = 223 \text{ W/m} \quad <$$

$$q'_{conv} = 7.83 \text{ W/m}^2 \cdot \text{K} \pi (0.020 \text{ m}) (65 - 30) \text{ K} = 17.2 \text{ W/m} \quad <$$

$$\text{where } h = 1.21 \text{ W} \cdot \text{m}^{-1.75} \cdot \text{K}^{-1.25} (0.020 \text{ m})^{-0.25} (65 - 30)^{0.25} = 7.83 \text{ W/m}^2 \cdot \text{K}$$

$$I^2 R'_e = I^2 (198.2 \times 10^{-6} \Omega \cdot \text{m}) / \pi (0.020)^2 \text{ m}^2 / 4 = 6.31 \times 10^{-5} I^2 \text{ W/m}$$

$$\text{where } \rho_e = 0.0171 \times 10^{-6} \Omega \cdot \text{m} \left[1 + 0.00396 \text{ K}^{-1} (65 - 25) \text{ K} \right] = 198.2 \mu\Omega \cdot \text{m}$$

The maximum allowable current capacity and the ratio of the convection to total heat transfer rate are

$$I = 1950 \text{ A} \quad q'_{cv} / (q'_{cv} + q'_{rad}) = q'_{cv} / q'_{tot} = 0.072 \quad <$$

For this operating condition, convection heat transfer is only 7.2% of the total heat transfer.

(b) Using these equations in the Workspace of IHT, the bus-bar operating temperature is calculated and plotted as a function of the current for the range $100 \leq I \leq 5000$ A for diameters of 10, 20 and 40 mm. Also shown below is the corresponding graph of the ratio (expressed in percentage units) of the heat transfer by convection to the total heat transfer, q'_{cv} / q'_{tot} .

Continued

PROBLEM 1.46 (Cont.)

COMMENTS: (1) The trade-off between current-carrying capacity, operating temperature and bar diameter is shown in the first graph. If the surface temperature is not to exceed 65°C, the maximum current capacities for the 10, 20 and 40-mm diameter bus bars are 960, 1950, and 4000 A, respectively.

(2) From the second graph with q'_{cv} / q'_{tot} vs. T , note that the convection heat transfer rate is always a small fraction of the total heat transfer. That is, radiation is the dominant mode of heat transfer. Note also that the convection contribution increases with increasing diameter.

(3) The Workspace for the IHT program to perform the parametric analysis and generate the graphs is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results.

```

PROBLEM 1.47

KNOWN: Elapsed times corresponding to a temperature change from 15 to 14°C for a reference sphere and test sphere of unknown composition suddenly immersed in a stirred water-ice mixture. Mass and specific heat of reference sphere.

FIND: Specific heat of the test sphere of known mass.

SCHEMATIC:

ASSUMPTIONS: (1) Spheres are of equal diameter, (2) Spheres experience temperature change from 15 to 14°C, (3) Spheres experience same convection heat transfer rate when the time rates of surface temperature are observed, (4) At any time, the temperatures of the spheres are uniform, (5) Negligible heat loss through the thermocouple wires.

PROPERTIES: Reference-grade sphere material: $c_r = 447 \text{ J/kg} \cdot \text{K}$.

ANALYSIS: Apply the conservation of energy requirement at an instant of time, Equation 1.11c, after a sphere has been immersed in the ice-water mixture at T_∞ .

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$$

$$-q_{\text{conv}} = Mc \frac{dT}{dt}$$

where $q_{\text{conv}} = h A_s (T - T_\infty)$. Since the temperatures of the spheres are uniform, the change in energy storage term can be represented with the time rate of temperature change, dT/dt . The convection heat rates are equal at this instant of time, and hence the change in energy storage terms for the reference (r) and test (t) spheres must be equal.

$$M_r c_r \left(\frac{dT}{dt} \right)_r = M_t c_t \left(\frac{dT}{dt} \right)_t$$

Approximating the instantaneous differential change, dT/dt , by the difference change over a short period of time, $\Delta T/\Delta t$, the specific heat of the test sphere can be calculated.

$$0.515 \text{ kg} \times 447 \text{ J/kg} \cdot \text{K} \times \frac{(15 - 14) \text{ K}}{6.35 \text{ s}} = 1.263 \text{ kg} \times c_t \times \frac{(15 - 14) \text{ K}}{4.59 \text{ s}}$$

$$c_t = 132 \text{ J/kg} \cdot \text{K}$$

<

COMMENTS: Why was it important to perform the experiments with the reference and test spheres over the same temperature range (from 15 to 14°C)? Why does the analysis require that the spheres have uniform temperatures at all times?

PROBLEM 1.48

KNOWN: Inner surface heating and new environmental conditions associated with a spherical shell of prescribed dimensions and material.

FIND: (a) Governing equation for variation of wall temperature with time. Initial rate of temperature change, (b) Steady-state wall temperature, (c) Effect of convection coefficient on canister temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible temperature gradients in wall, (2) Constant properties, (3) Uniform, time-independent heat flux at inner surface.

PROPERTIES: Table A.1, Stainless Steel, AISI 302: $\rho = 8055 \text{ kg/m}^3$, $c_p = 535 \text{ J/kg}\cdot\text{K}$.

ANALYSIS: (a) Performing an energy balance on the shell at an instant of time, $\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$.

Identifying relevant processes and solving for dT/dt ,

$$q_i''(4\pi r_i^2) - h(4\pi r_o^2)(T - T_\infty) = \rho \frac{4}{3}\pi(r_o^3 - r_i^3) c_p \frac{dT}{dt}$$

$$\frac{dT}{dt} = \frac{3}{\rho c_p (r_o^3 - r_i^3)} [q_i'' r_i^2 - h r_o^2 (T - T_\infty)].$$

Substituting numerical values for the initial condition, find

$$\left. \frac{dT}{dt} \right|_i = \frac{3 \left[10^5 \frac{\text{W}}{\text{m}^2} (0.5\text{m})^2 - 500 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (0.6\text{m})^2 (500 - 300) \text{K} \right]}{8055 \frac{\text{kg}}{\text{m}^3} 535 \frac{\text{J}}{\text{kg} \cdot \text{K}} [(0.6)^3 - (0.5)^3] \text{m}^3}$$

$$\left. \frac{dT}{dt} \right|_i = -0.084 \text{ K/s}.$$

(b) Under steady-state conditions with $\dot{E}_{st} = 0$, it follows that

$$q_i''(4\pi r_i^2) = h(4\pi r_o^2)(T - T_\infty)$$

$$T = T_\infty + \frac{q_i''}{h} \left(\frac{r_i}{r_o} \right)^2 = 300\text{K} + \frac{10^5 \text{ W/m}^2}{500 \text{ W/m}^2 \cdot \text{K}} \left(\frac{0.5\text{m}}{0.6\text{m}} \right)^2 = 439\text{K}$$

Continued

PROBLEM 1.48 (Cont.)

(c) Parametric calculations were performed using the IHT *First Law Model* for an *Isothermal Hollow Sphere*. As shown below, there is a sharp increase in temperature with decreasing values of $h < 1000 \text{ W/m}^2\cdot\text{K}$. For $T > 380 \text{ K}$, boiling will occur at the canister surface, and for $T > 410 \text{ K}$ a condition known as film boiling (Chapter 10) will occur. The condition corresponds to a precipitous reduction in h and increase in T .

Although the canister remains well below the melting point of stainless steel for $h = 100 \text{ W/m}^2\cdot\text{K}$, boiling should be avoided, in which case the convection coefficient should be maintained at $h > 1000 \text{ W/m}^2\cdot\text{K}$.

COMMENTS: The governing equation of part (a) is a first order, nonhomogenous differential equation with constant coefficients. Its solution is $\theta = (S/R)(1 - e^{-Rt}) + \theta_i e^{-Rt}$, where $\theta \equiv T - T_\infty$,

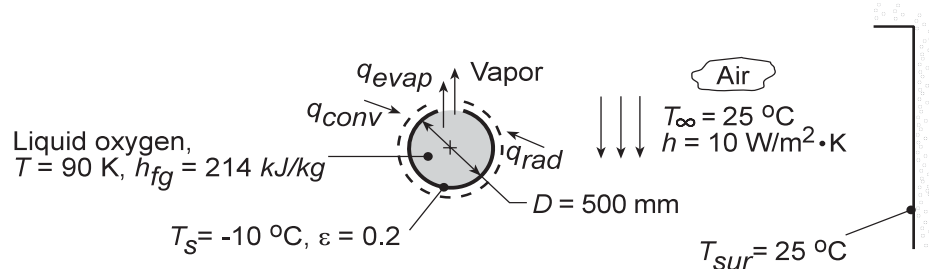

$S \equiv 3q_i'' r_i^2 / \rho c_p (r_o^3 - r_i^3)$, $R = 3hr_o^2 / \rho c_p (r_o^3 - r_i^3)$. Note results for $t \rightarrow \infty$ and for $S = 0$.

PROBLEM 1.49

KNOWN: Boiling point and latent heat of liquid oxygen. Diameter and emissivity of container. Free convection coefficient and temperature of surrounding air and walls.

FIND: Mass evaporation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Temperature of container outer surface equals boiling point of oxygen.

ANALYSIS: (a) Applying mass and energy balances to a control surface about the container, it follows that, at any instant,

$$\frac{dm_{st}}{dt} = -\dot{m}_{out} = -\dot{m}_{evap} \quad \frac{dE_{st}}{dt} = \dot{E}_{in} - \dot{E}_{out} = q_{conv} + q_{rad} - q_{evap} \quad (1a,b)$$

With h_f as the enthalpy of liquid oxygen and h_g as the enthalpy of oxygen vapor, we have

$$E_{st} = m_{st} h_f \quad q_{evap} = \dot{m}_{out} h_g \quad (2a,b)$$

Combining Equations (1a) and (2a,b), Equation (1b) becomes (with $h_{fg} = h_g - h_f$)

$$\dot{m}_{out} h_{fg} = q_{conv} + q_{rad} \quad \dot{m}_{evap} = (q_{conv} + q_{rad}) / h_{fg} = \left[h(T_{\infty} - T_s) + \varepsilon \sigma (T_{sur}^4 - T_s^4) \right] \pi D^2 / h_{fg} \quad (3)$$

$$\dot{m}_{evap} = \frac{\left[10 \text{ W/m}^2 \cdot \text{K} (298 - 263) \text{ K} + 0.2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298^4 - 263^4 \text{ K}^4) \right] \pi (0.5 \text{ m})^2}{214 \text{ kJ/kg}}$$

$$\dot{m}_{evap} = (350 + 35.2) \text{ W/m}^2 (0.785 \text{ m}^2) / 214 \text{ kJ/kg} = 1.41 \times 10^{-3} \text{ kg/s} \quad <$$

(b) Using Equation (3), the mass rate of vapor production can be determined for the range of emissivity 0.2 to 0.94. The effect of increasing emissivity is to increase the heat rate into the container and, hence, increase the vapor production rate.

COMMENTS: To reduce the loss of oxygen due to vapor production, insulation should be applied to the outer surface of the container, in order to reduce q_{conv} and q_{rad} . Note from the calculations in part (a), that heat transfer by convection is greater than by radiation exchange.

PROBLEM 1.50

KNOWN: Frost formation of 2-mm thickness on a freezer compartment. Surface exposed to convection process with ambient air.

FIND: Time required for the frost to melt, t_m .

SCHEMATIC:

ASSUMPTIONS: (1) Frost is isothermal at the fusion temperature, T_f , (2) The water melt falls away from the exposed surface, (3) Frost exchanges radiation with surrounding frost, so net radiation exchange is negligible, and (4) Backside surface of frost formation is adiabatic.

PROPERTIES: Frost, $\rho_f = 770 \text{ kg/m}^3$, $h_{sf} = 334 \text{ kJ/kg}$.

ANALYSIS: The time t_m required to melt a 2-mm thick frost layer may be determined by applying a mass balance and an energy balance (Eq. 1.11b) over the differential time interval dt to a control volume around the frost layer.

$$dm_{st} = -\dot{m}_{out} dt \quad dE_{st} = (\dot{E}_{in} - \dot{E}_{out}) dt \quad (1a,b)$$

With h_f as the enthalpy of the melt and h_s as the enthalpy of frost, we have

$$dE_{st} = dm_{st} h_s \quad \dot{E}_{out} dt = \dot{m}_{out} h_f dt \quad (2a,b)$$

Combining Eqs. (1a) and (2a,b), Eq. (1b) becomes (with $h_{sf} = h_f - h_s$)

$$\dot{m}_{out} h_{sf} dt = \dot{E}_{in} dt = q''_{conv} A_s dt$$

Integrating both sides of the equation with respect to time, find

$$\rho_f A_s h_{sf} x_o = h A_s (T_\infty - T_f) t_m$$

$$t_m = \frac{\rho_f h_{sf} x_o}{h(T_\infty - T_f)}$$

$$t_m = \frac{700 \text{ kg/m}^3 \times 334 \times 10^3 \text{ J/kg} \times 0.002 \text{ m}}{2 \text{ W/m}^2 \cdot \text{K} (20 - 0) \text{ K}} = 11,690 \text{ s} = 3.2 \text{ hour} \quad <$$

COMMENTS: (1) The energy balance could be formulated intuitively by recognizing that the total heat *in* by convection during the time interval t_m ($q''_{conv} \cdot t_m$) must be equal to the total latent energy for melting the frost layer ($\rho x_o h_{sf}$). This equality is directly comparable to the derived expression above for t_m .

PROBLEM 1.51

KNOWN: Vertical slab of Woods metal initially at its fusion temperature, T_f , joined to a substrate. Exposed surface is irradiated with laser source, G_l (W/m^2).

FIND: Instantaneous rate of melting per unit area, \dot{m}_m'' ($\text{kg}/\text{s}\cdot\text{m}^2$), and the material removed in a period of 2 s, (a) Neglecting heat transfer from the irradiated surface by convection and radiation exchange, and (b) Allowing for convection and radiation exchange.

SCHEMATIC:

ASSUMPTIONS: (1) Woods metal slab is isothermal at the fusion temperature, T_f , and (2) The melt runs off the irradiated surface.

ANALYSIS: (a) The instantaneous rate of melting per unit area may be determined by applying a mass balance and an energy balance (Equation 1.11c) on the metal slab at an instant of time neglecting convection and radiation exchange from the irradiated surface.

$$\dot{m}_{st}'' = \dot{m}_{in}'' - \dot{m}_{out}'' \quad \dot{E}_{in}'' - \dot{E}_{out}'' = \dot{E}_{st}'' \quad (1a,b)$$

With h_f as the enthalpy of the melt and h_s as the enthalpy of the solid, we have

$$\dot{E}_{st}'' = \dot{m}_{st}'' h_s \quad \dot{E}_{out}'' = \dot{m}_{out}'' h_f \quad (2a,b)$$

Combining Equations (1a) and (2a,b), Equation (1b) becomes (with $h_{sf} = h_f - h_s$)

$$\dot{m}_{out}'' h_{sf} = \dot{E}_{in}'' = \alpha_l G_l$$

Thus the rate of melting is

$$\dot{m}_{out}'' = \alpha_l G_l / h_{sf} = 0.4 \times 5000 \text{ W/m}^2 / 33,000 \text{ J/kg} = 60.6 \times 10^{-3} \text{ kg/s} \times \text{m}^2 <$$

The material removed in a 2s period per unit area is

$$M_{2s}'' = \dot{m}_{out}'' \times \Delta t = 121 \text{ g/m}^2 <$$

(b) The energy balance considering convection and radiation exchange with the surroundings yields

$$\dot{m}_{out}'' h_{sf} = \alpha_l G_l - q_{cv}'' - q_{rad}''$$

$$q_{cv}'' = h(T_f - T_\infty) = 15 \text{ W/m}^2 \cdot \text{K}(72 - 20) \text{ K} = 780 \text{ W/m}^2$$

$$q_{rad}'' = \epsilon \sigma (T_f^4 - T_\infty^4) = 0.4 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}([72 + 273]^4 - [20 + 273]^4) \text{ K}^4 = 154 \text{ W/m}^2$$

$$\dot{m}_{out}'' = 32.3 \times 10^{-3} \text{ kg/s} \cdot \text{m}^2 \quad M_{2s}'' = 64 \text{ g/m}^2 <$$

COMMENTS: (1) The effects of heat transfer by convection and radiation reduce the estimate for the material removal rate by a factor of two. The heat transfer by convection is nearly 5 times larger than by radiation exchange.

Continued...

PROBLEM 1.51 (Conti.)

- (2) Suppose the work piece were horizontal, rather than vertical, and the melt puddled on the surface rather than ran off. How would this affect the analysis?
- (3) Lasers are common heating sources for metals processing, including the present application of melting (heat transfer with phase change), as well as for heating work pieces during milling and turning (laser-assisted machining).

PROBLEM 1.52

KNOWN: Hot formed paper egg carton of prescribed mass, surface area, and water content exposed to infrared heater providing known radiant flux.

FIND: Whether water content can be reduced by 10% of the total mass during the 18s period carton is on conveyor.

SCHEMATIC:

ASSUMPTIONS: (1) All the radiant flux from the heater bank causes evaporation of water, (2) Negligible heat loss from carton by convection and radiation, (3) Negligible mass loss occurs from bottom side.

PROPERTIES: Water (given): $h_{fg} = 2400 \text{ kJ/kg}$.

ANALYSIS: Define a control surface about the carton, and write conservation of mass and energy for an interval of time, Δt ,

$$\Delta m_{st} = -\dot{m}_{out} \Delta t \quad \Delta E_{st} = (\dot{E}_{in} - \dot{E}_{out}) \Delta t \quad (1a,b)$$

With h_f as the enthalpy of the liquid water and h_g as the enthalpy of water vapor, we have

$$\Delta E_{st} = \Delta m_{st} h_f \quad \dot{E}_{out} \Delta t = \dot{m}_{out} h_g \Delta t \quad (2a,b)$$

Combining Equations (1a) and (2a,b), Equation (1b) becomes (with $h_{fg} = h_g - h_f$)

$$\dot{m}_{out} h_{fg} \Delta t = \dot{E}_{in} \Delta t = q_h'' A_s \Delta t$$

where q_h'' is the absorbed radiant heat flux from the heater. Hence,

$$\Delta m = \dot{m}_{out} \Delta t = q_h'' A_s \Delta t / h_{fg} = 5000 \text{ W/m}^2 \times 0.0625 \text{ m}^2 \times 18 \text{ s} / 2400 \text{ kJ/kg} = 0.00234 \text{ kg}$$

The chief engineer's requirement was to remove 10% of the water content, or

$$\Delta m_{req} = M \times 0.10 = 0.220 \text{ kg} \times 0.10 = 0.022 \text{ kg}$$

which is nearly an order of magnitude larger than the evaporative loss. Considering heat losses by convection and radiation, the actual water removal from the carton will be less than Δm . Hence, the purchase should not be recommended, since the desired water removal cannot be achieved. <

PROBLEM 1.53

KNOWN: Average heat sink temperature when total dissipation is 20 W with prescribed air and surroundings temperature, sink surface area and emissivity.

FIND: Sink temperature when dissipation is 30 W.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) All dissipated power in devices is transferred to the sink, (3) Sink is isothermal, (4) Surroundings and air temperature remain the same for both power levels, (5) Convection coefficient is the same for both power levels, (6) Heat sink is a small surface within a large enclosure, the surroundings.

ANALYSIS: Define a control volume around the heat sink. Power dissipated within the devices is transferred into the sink, while the sink loses heat to the ambient air and surroundings by convection and radiation exchange, respectively.

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= 0 \\ P_e - hA_s(T_s - T_\infty) - A_s \varepsilon \sigma (T_s^4 - T_{sur}^4) &= 0. \end{aligned} \quad (1)$$

Consider the situation when $P_e = 20$ W for which $T_s = 42^\circ\text{C}$; find the value of h .

$$\begin{aligned} h &= \left[P_e / A_s - \varepsilon \sigma (T_s^4 - T_{sur}^4) \right] / (T_s - T_\infty) \\ h &= \left[20 \text{ W} / 0.045 \text{ m}^2 - 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (315^4 - 300^4) \text{ K}^4 \right] / (315 - 300) \text{ K} \\ h &= 24.4 \text{ W} / \text{m}^2 \cdot \text{K}. \end{aligned}$$

For the situation when $P_e = 30$ W, using this value for h with Eq. (1), obtain

$$\begin{aligned} 30 \text{ W} - 24.4 \text{ W/m}^2 \cdot \text{K} \times 0.045 \text{ m}^2 (T_s - 300) \text{ K} \\ - 0.045 \text{ m}^2 \times 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_s^4 - 300^4) \text{ K}^4 &= 0 \\ 30 &= 1.098(T_s - 300) + 2.041 \times 10^{-9} (T_s^4 - 300^4). \end{aligned}$$

By trial-and-error, find

$$T_s \approx 322 \text{ K} = 49^\circ\text{C}.$$

<

COMMENTS: (1) It is good practice to express all temperatures in kelvin units when using energy balances involving radiation exchange.

(2) Note that we have assumed A_s is the same for the convection and radiation processes. Since not all portions of the fins are completely exposed to the surroundings, $A_{s,rad}$ is less than $A_{s,conv} = A_s$.

(3) Is the assumption that the heat sink is isothermal reasonable?

PROBLEM 1.54

KNOWN: Number and power dissipation of PCBs in a computer console. Convection coefficient associated with heat transfer from individual components in a board. Inlet temperature of cooling air and fan power requirement. Maximum allowable temperature rise of air. Heat flux from component most susceptible to thermal failure.

FIND: (a) Minimum allowable volumetric flow rate of air, (b) Preferred location and corresponding surface temperature of most thermally sensitive component.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant air properties, (3) Negligible potential and kinetic energy changes of air flow, (4) Negligible heat transfer from console to ambient air, (5) Uniform convection coefficient for all components.

ANALYSIS: (a) For a control surface about the air space in the console, conservation of energy for an open system, Equation (1.11d), reduces to

$$\dot{m}(u_t + pv)_{\text{in}} - \dot{m}(u_t + pv)_{\text{out}} + q - \dot{W} = 0$$

where $u_t + pv = i$, $q = 5P_b$, and $\dot{W} = -P_f$. Hence, with $\dot{m}(i_{\text{in}} - i_{\text{out}}) = \dot{m}c_p(T_{\text{in}} - T_{\text{out}})$,

$$\dot{m}c_p(T_{\text{out}} - T_{\text{in}}) = 5P_b + P_f$$

For a maximum allowable temperature rise of 15°C , the required mass flow rate is

$$\dot{m} = \frac{5P_b + P_f}{c_p(T_{\text{out}} - T_{\text{in}})} = \frac{5 \times 20 \text{ W} + 25 \text{ W}}{1007 \text{ J/kg} \cdot \text{K}(15^\circ\text{C})} = 8.28 \times 10^{-3} \text{ kg/s}$$

The corresponding volumetric flow rate is

$$\dot{V} = \frac{\dot{m}}{\rho} = \frac{8.28 \times 10^{-3} \text{ kg/s}}{1.161 \text{ kg/m}^3} = 7.13 \times 10^{-3} \text{ m}^3/\text{s} \quad <$$

(b) The component which is most susceptible to thermal failure should be mounted at the bottom of one of the PCBs, where the air is coolest. From the corresponding form of Newton's law of cooling, $q'' = h(T_s - T_{\text{in}})$, the surface temperature is

$$T_s = T_{\text{in}} + \frac{q''}{h} = 20^\circ\text{C} + \frac{1 \times 10^4 \text{ W/m}^2}{200 \text{ W/m}^2 \cdot \text{K}} = 70^\circ\text{C} \quad <$$

COMMENTS: (1) Although the mass flow rate is invariant, the volumetric flow rate increases as the air is heated in its passage through the console, causing a reduction in the density. However, for the prescribed temperature rise, the change in ρ , and hence the effect on \dot{V} , is small. (2) If the thermally sensitive component were located at the top of a PCB, it would be exposed to warmer air ($T_o = 35^\circ\text{C}$) and the surface temperature would be $T_s = 85^\circ\text{C}$.

PROBLEM 1.55

KNOWN: Top surface of car roof absorbs solar flux, $q''_{S,abs}$, and experiences for case (a): convection with air at T_∞ and for case (b): the same convection process and radiation emission from the roof.

FIND: Temperature of the roof, T_s , for the two cases. Effect of airflow on roof temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer to auto interior, (3) Negligible radiation from atmosphere.

ANALYSIS: (a) Apply an energy balance to the control surfaces shown on the schematic. For an instant of time, $\dot{E}_{in} - \dot{E}_{out} = 0$. Neglecting radiation emission, the relevant processes are convection between the plate and the air, q''_{conv} , and the absorbed solar flux, $q''_{S,abs}$. Considering the roof to have an area A_s ,

$$q''_{S,abs} \cdot A_s - hA_s (T_s - T_\infty) = 0$$

$$T_s = T_\infty + q''_{S,abs}/h$$

$$T_s = 20^\circ\text{C} + \frac{800\text{W/m}^2}{12\text{W/m}^2 \cdot \text{K}} = 20^\circ\text{C} + 66.7^\circ\text{C} = 86.7^\circ\text{C} \quad <$$

(b) With radiation emission from the surface, the energy balance has the form

$$q''_{S,abs} \cdot A_s - q_{conv} - E \cdot A_s = 0$$

$$q''_{S,abs}A_s - hA_s (T_s - T_\infty) - \varepsilon A_s \sigma T_s^4 = 0.$$

Substituting numerical values, with temperature in absolute units (K),

$$800 \frac{\text{W}}{\text{m}^2} - 12 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (T_s - 293\text{K}) - 0.8 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} T_s^4 = 0$$

$$12T_s + 4.536 \times 10^{-8} T_s^4 = 4316$$

It follows that $T_s = 320 \text{ K} = 47^\circ\text{C}$. <

Continued.....

PROBLEM 1.55 (Cont.)

(c) Parametric calculations were performed using the IHT *First Law Model* for an *Isothermal Plane Wall*. As shown below, the roof temperature depends strongly on the velocity of the auto relative to the ambient air. For a convection coefficient of $h = 40 \text{ W/m}^2\cdot\text{K}$, which would be typical for a velocity of 55 mph, the roof temperature would exceed the ambient temperature by less than 10°C .

COMMENTS: By considering radiation emission, T_s decreases, as expected. Note the manner in which q''_{conv} is formulated using Newton's law of cooling; since q''_{conv} is shown leaving the control surface, the rate equation must be $h(T_s - T_\infty)$ and not $h(T_\infty - T_s)$.

PROBLEM 1.56

KNOWN: Hot plate suspended in a room, plate temperature, room temperature and surroundings temperature, convection coefficient and plate emissivity, mass and specific heat of the plate.

FIND: (a) The time rate of change of the plate temperature, and (b) Heat loss by convection and heat loss by radiation.

SCHEMATIC:

ASSUMPTIONS: (1) Plate is isothermal and at uniform temperature, (2) Large surroundings, (3) Negligible heat loss through suspension wires.

ANALYSIS: For a control volume about the plate, the conservation of energy requirement is

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}} \quad (1)$$

where $\dot{E}_{\text{st}} = Mc_p \frac{dT}{dt}$ (2)

and $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \epsilon A \sigma (T_{\text{sur}}^4 - T_s^4) + hA(T_{\infty} - T_s)$ (3)

Combining Eqs. (1) through (3) yields $\frac{dT}{dt} = \frac{A[\epsilon \sigma (T_{\text{sur}}^4 - T_s^4) + h(T_{\infty} - T_s)]}{Mc_p}$

Noting that $T_{\text{sur}} = 25^{\circ}\text{C} + 273 \text{ K} = 298 \text{ K}$ and $T_s = 225^{\circ}\text{C} + 273 \text{ K} = 498 \text{ K}$,

$$\frac{dT}{dt} = \frac{\{2 \times 0.3 \text{ m} \times 0.3 \text{ m} [0.42 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times (498^4 - 298^4) \text{ K}^4] + 6.4 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times (25^{\circ}\text{C} - 225^{\circ}\text{C})\}}{3.75 \text{ kg} \times 2770 \frac{\text{J}}{\text{kg} \cdot \text{K}}}$$

$$= -0.044 \text{ K/s} \quad <$$

The heat loss by radiation is the first term in the numerator of the preceding expression and is

$$q_{\text{rad}} = 230 \text{ W} \quad <$$

The heat loss by convection is the second term in the preceding expression and is

$$q_{\text{conv}} = 230 \text{ W} \quad <$$

COMMENTS: (1) Note the importance of using kelvins when working with radiation heat transfer. (2) The temperature difference in Newton's law of cooling may be expressed in either kelvins or degrees Celsius. (3) Radiation and convection losses are of the same magnitude. This is typical of many natural convection systems involving gases such as air.

PROBLEM 1.57

KNOWN: Daily thermal energy generation, surface area, temperature of the environment, and heat transfer coefficient.

FIND: (a) Skin temperature when the temperature of the environment is 20°C, and (b) Rate of perspiration to maintain skin temperature of 33°C when the temperature of the environment is 33°C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Thermal energy is generated at a constant rate throughout the day, (3) Air and surrounding walls are at same temperature, (4) Skin temperature is uniform, (5) Bathing suit has no effect on heat loss from body, (6) Heat loss is by convection and radiation to the environment, and by perspiration in Part 2. (Heat loss due to respiration, excretion of waste, etc., is negligible.), (7) Large surroundings.

PROPERTIES: Table A.11, skin: $\varepsilon = 0.95$, Table A.6, water (306 K): $\rho = 994 \text{ kg/m}^3$, $h_{fg} = 2421 \text{ kJ/kg}$.

ANALYSIS:

(a) The rate of energy generation is:

$$\dot{E}_g = 2000 \times 10^3 \text{ cal/day} / (0.239 \text{ cal/J} \times 86,400 \text{ s/day}) = 96.9 \text{ W}$$

Under steady-state conditions, an energy balance on the human body yields:

$$\dot{E}_g - \dot{E}_{\text{out}} = 0$$

Thus $\dot{E}_{\text{out}} = \dot{q} = 96.9 \text{ W}$. Energy outflow is due to convection and net radiation from the surface to the environment, Equations 1.3a and 1.7, respectively.

$$\dot{E}_{\text{out}} = hA(T_s - T_\infty) + \varepsilon\sigma A(T_s^4 - T_{\text{sur}}^4)$$

Substituting numerical values

Continued...

PROBLEM 1.57 (Cont.)

$$96.9 \text{ W} = 3 \text{ W/m}^2 \cdot \text{K} \times 1.8 \text{ m}^2 \times (T_s - 293 \text{ K}) \\ + 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 1.8 \text{ m}^2 \times (T_s^4 - (293 \text{ K})^4)$$

and solving either by trial-and-error or using *IHT* or other equation solver, we obtain

$$T_s = 299 \text{ K} = 26^\circ\text{C}$$

<

Since the comfortable range of skin temperature is typically $32 - 35^\circ\text{C}$, we usually wear clothing warmer than a bathing suit when the temperature of the environment is 20°C .

(b) If the skin temperature is 33°C when the temperature of the environment is 33°C , there will be no heat loss due to convection or radiation. Thus, all the energy generated must be removed due to perspiration:

$$\dot{E}_{\text{out}} = \dot{m}h_{\text{fg}}$$

We find:

$$\dot{m} = \dot{E}_{\text{out}}/h_{\text{fg}} = 96.9 \text{ W}/2421 \text{ kJ/kg} = 4.0 \times 10^{-5} \text{ kg/s}$$

This is the perspiration rate in mass per unit time. The volumetric rate is:

$$\dot{V} = \dot{m}/\rho = 4.0 \times 10^{-5} \text{ kg/s} / 994 \text{ kg/m}^3 = 4.0 \times 10^{-8} \text{ m}^3/\text{s} = 4.0 \times 10^{-5} \text{ L/s}$$

<

COMMENTS: (1) In Part 1, heat losses due to convection and radiation are 32.4 W and 60.4 W, respectively. Thus, it would not have been reasonable to neglect radiation. Care must be taken to include radiation when the heat transfer coefficient is small, even if the problem statement does not give any indication of its importance. (2) The rate of thermal energy generation is not constant throughout the day; it adjusts to maintain a constant core temperature. Thus, the energy generation rate may decrease when the temperature of the environment goes up, or increase (for example, by shivering) when the temperature of the environment is low. (3) The skin temperature is not uniform over the entire body. For example, the extremities are usually cooler. Skin temperature also adjusts in response to changes in the environment. As the temperature of the environment increases, more blood flow will be directed near the surface of the skin to increase its temperature, thereby increasing heat loss. (4) If the perspiration rate found in Part 2 was maintained for eight hours, the person would lose 1.2 liters of liquid. This demonstrates the importance of consuming sufficient amounts of liquid in warm weather.

PROBLEM 1.58

KNOWN: Electrolytic membrane dimensions, bipolar plate thicknesses, desired operating temperature and surroundings as well as air temperatures.

FIND: (a) Electrical power produced by stack that is 200 mm in length for bipolar plate thicknesses $1 \text{ mm} < t_{bp} < 10 \text{ mm}$, (b) Surface temperature of stack for various bipolar plate thicknesses, (c) Identify strategies to promote uniform temperature, identify effect of various air and surroundings temperatures, identify membrane most likely to fail.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Large surroundings, (3) Surface emissivity and absorptivity are the same, (4) Negligible energy entering or leaving the control volume due to gas or liquid flows, (5) Negligible energy loss or gain from or to the stack by conduction.

ANALYSIS: The length of the fuel cell is related to the number of membranes and the thickness of the membranes and bipolar plates as follows.

$$L_{\text{stack}} = N \times t_m + (N + 1) \times t_{bp} = N \times (t_m + t_{bp}) + t_{bp}$$

$$\text{For } t_{bp} = 1 \text{ mm, } 200 \times 10^{-3} \text{ m} = N \times (0.43 \times 10^{-3} \text{ m} + 1.0 \times 10^{-3} \text{ m}) + 1.0 \times 10^{-3} \text{ m} \\ \text{or } N = 139$$

$$\text{For } t_{bp} = 10 \text{ mm, } 200 \times 10^{-3} \text{ m} = N \times (0.43 \times 10^{-3} \text{ m} + 10 \times 10^{-3} \text{ m}) + 10 \times 10^{-3} \text{ m} \\ \text{or } N = 18$$

(a) For $t_{bp} = 1 \text{ mm}$, the electrical power produced by the stack is

$$P = E_{\text{STACK}} \times I = N \times E_c \times I = 139 \times 0.6 \text{ V} \times 60 \text{ A} = 5000 \text{ W} = 5 \text{ kW} \quad <$$

and the thermal energy produced by the stack is

$$\dot{E}_g = N \times \dot{E}_{c,g} = 139 \times 45 \text{ W} = 6,255 \text{ W} = 6.26 \text{ kW} \quad <$$

Continued...

PROBLEM 1.58 (Conti.)

Proceeding as before for $t_{bp} = 10 \text{ mm}$, we find $P = 648 \text{ W} = 0.65 \text{ kW}$; $\dot{E}_g = 810 \text{ W} = 0.81 \text{ kW} <$

(b) An energy balance on the control volume yields

$$\dot{E}_g - \dot{E}_{out} = 0 \quad \text{or} \quad \dot{E}_g - A(q''_{conv} + q''_{rad}) = 0 \quad (1)$$

Substituting Eqs. 1.3a and 1.7 into Eq. (1) yields

$$\dot{E}_g - A[h(T_s - T_\infty) + \varepsilon\sigma(T_s^4 - T_{sur}^4)] = 0$$

where $A = 4 \times L \times w + 2 \times H \times w$

$$= 4 \times 200 \times 10^{-3} \text{ m} \times 100 \times 10^{-3} \text{ m} + 2 \times 100 \times 10^{-3} \text{ m} \times 100 \times 10^{-3} \text{ m} = 0.1 \text{ m}^2$$

For $t_{bp} = 1 \text{ mm}$ and $\dot{E}_g = 6255 \text{ W}$,

$$6255 \text{ W} - 0.1 \text{ m}^2 \times [150 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times (T_s - 298) \text{ K} + 0.88 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times (T_s^4 - T_{sur}^4) \text{ K}^4] = 0$$

The preceding equation may be solved to yield

$$T_s = 656 \text{ K} = 383^\circ\text{C}$$

Therefore, for $t_{bp} = 1 \text{ mm}$ the surface temperature exceeds the maximum allowable operating temperature and the stack must be cooled. <

For $t_{bp} = 10 \text{ mm}$ and $\dot{E}_g = 810 \text{ W}$, $T_s = 344 \text{ K} = 71^\circ\text{C}$ and the stack may need to be heated to operate at $T = 80^\circ\text{C}$. <

(c) To decrease the stack temperature, the emissivity of the surface may be increased, the bipolar plates may be made larger than $100 \text{ mm} \times 100 \text{ mm}$ to act as *cooling fins*, internal channels might be machined in the bipolar plates to carry a pumped coolant, and the convection coefficient may be increased by using forced convection from a fan. The stack temperature can be increased by insulating the external surfaces of the stack.

Uniform internal temperatures may be promoted by using materials of high thermal conductivity. The operating temperature of the stack will shift upward as either the surroundings or ambient temperature increases. The membrane that experiences the highest temperature will be most likely to fail. Unfortunately, the highest temperatures are likely to exist near the center of the stack, making stack repair difficult and expensive. <

COMMENTS: (1) There is a tradeoff between the power produced by the stack, and the operating temperature of the stack. (2) Manufacture of the bipolar plates becomes difficult, and cooling channels are difficult to incorporate into the design, as the bipolar plates become thinner. (3) If one membrane fails, the entire stack fails since the membranes are connected in series electrically.

PROBLEM 1.59

KNOWN: Thermal conductivity, thickness and temperature difference across a sheet of rigid extruded insulation. Cold wall temperature, surroundings temperature, ambient temperature and emissivity.

FIND: (a) The value of the convection heat transfer coefficient on the cold wall side in units of $\text{W}/\text{m}^2\cdot^\circ\text{C}$ or $\text{W}/\text{m}^2\cdot\text{K}$, and, (b) The cold wall surface temperature for emissivities over the range $0.05 \leq \varepsilon \leq 0.95$ for a hot wall temperature of $T_1 = 30^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Steady-state conditions, (c) Constant properties, (4) Large surroundings.

ANALYSIS:

(a) An energy balance on the control surface shown in the schematic yields

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}} \quad \text{or} \quad q_{\text{cond}} = q_{\text{conv}} + q_{\text{rad}}$$

Substituting from Fourier's law, Newton's law of cooling, and Eq. 1.7 yields

$$k \frac{T_1 - T_2}{L} = h(T_2 - T_\infty) + \varepsilon\sigma(T_2^4 - T_{\text{sur}}^4) \quad (1)$$

$$\text{or} \quad h = \frac{1}{(T_2 - T_\infty)} \left[k \frac{T_1 - T_2}{L} - \varepsilon\sigma(T_2^4 - T_{\text{sur}}^4) \right]$$

Substituting values,

$$h = \frac{1}{(20 - 5)^\circ\text{C}} \left[0.029 \frac{\text{W}}{\text{m} \cdot \text{K}} \times \frac{(30 - 20)^\circ\text{C}}{0.02 \text{ m}} - 0.95 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} (293^4 - 320^4) \text{ K}^4 \right]$$

$$h = 12.2 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \quad <$$

Continued....

PROBLEM 1.59 (Cont.)

(b) Equation (1) may be solved iteratively to find T_2 for any emissivity ϵ . *IHT* was used for this purpose, yielding the following.

COMMENTS: (1) Note that as the wall emissivity increases, the surface temperature increases since the surroundings temperature is relatively hot. (2) The *IHT* code used in part (b) is shown below. (3) It is a good habit to work in temperature units of kelvins when radiation heat transfer is included in the solution of the problem.

//Problem 1.59

$h = 12.2$ //W/m²·K (convection coefficient)
 $L = 0.02$ //m (sheet thickness)
 $k = 0.029$ //W/m·K (thermal conductivity)
 $T_1 = 30 + 273$ //K (hot wall temperature)
 $T_{\text{sur}} = 320$ //K (surroundings temperature)
 $\sigma = 5.67 \times 10^{-8}$ //W/m²·K⁴ (Stefan -Boltzmann constant)
 $T_{\text{inf}} = 5 + 273$ //K (ambient temperature)
 $e = 0.95$ //emissivity

//Equation (1) is

$$k \cdot (T_1 - T_2) / L = h \cdot (T_2 - T_{\text{inf}}) + e \cdot \sigma \cdot (T_2^4 - T_{\text{sur}}^4)$$

PROBLEM 1.60

KNOWN: Thickness and thermal conductivity, k , of an oven wall. Temperature and emissivity, ϵ , of front surface. Temperature and convection coefficient, h , of air. Temperature of large surroundings.

FIND: (a) Temperature of back surface, (b) Effect of variations in k , h and ϵ .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Radiation exchange with large surroundings.

ANALYSIS: (a) Applying an energy balance, Eq. 1.13, at an instant of time to the front surface and substituting the appropriate rate equations, Eqs. 1.2, 1.3a and 1.7, find

$$k \frac{T_1 - T_2}{L} = h(T_2 - T_\infty) + \epsilon \sigma (T_2^4 - T_{sur}^4).$$

Substituting numerical values, find

$$T_1 - T_2 = \frac{0.05 \text{ m}}{0.7 \text{ W/m} \cdot \text{K}} \left[20 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} 100 \text{ K} + 0.8 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \left[(400 \text{ K})^4 - (300 \text{ K})^4 \right] \right] = 200 \text{ K}.$$

Since $T_2 = 400 \text{ K}$, it follows that $T_1 = 600 \text{ K}$. <

(b) Parametric effects may be evaluated by using the IHT *First Law Model* for a *Nonisothermal Plane Wall*. Changes in k strongly influence conditions for $k < 20 \text{ W/m} \cdot \text{K}$, but have a negligible effect for larger values, as T_2 approaches T_1 and the heat fluxes approach the corresponding limiting values

Continued...

PROBLEM 1.60 (Cont.)

The implication is that, for $k > 20 \text{ W/m}\cdot\text{K}$, heat transfer by conduction in the wall is extremely efficient relative to heat transfer by convection and radiation, which become the *limiting* heat transfer processes. Larger fluxes could be obtained by increasing ϵ and h and/or by decreasing T_∞ and T_{sur} .

With increasing h , the front surface is cooled more effectively (T_2 decreases), and although q''_{rad} decreases, the reduction is exceeded by the increase in q''_{conv} . With a reduction in T_2 and fixed values of k and L , q''_{cond} must also increase.

The surface temperature also decreases with increasing ϵ , and the increase in q''_{rad} exceeds the reduction in q''_{conv} , allowing q''_{cond} to increase with ϵ .

COMMENTS: Conservation of energy, of course, dictates that, irrespective of the prescribed conditions, $q''_{\text{cond}} = q''_{\text{conv}} + q''_{\text{rad}}$.

PROBLEM 1.61

KNOWN: Temperatures at 10 mm and 20 mm from the surface and in the adjoining airflow for a thick stainless steel casting.

FIND: Surface convection coefficient, h .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction in the x -direction, (3) Constant properties, (4) Negligible generation.

ANALYSIS: From a surface energy balance, it follows that

$$q''_{\text{cond}} = q''_{\text{conv}}$$

where the convection rate equation has the form

$$q''_{\text{conv}} = h (T_{\infty} - T_0),$$

and q''_{cond} can be evaluated from the temperatures prescribed at surfaces 1 and 2. That is, from Fourier's law,

$$q''_{\text{cond}} = k \frac{T_1 - T_2}{x_2 - x_1}$$

$$q''_{\text{cond}} = 15 \frac{\text{W}}{\text{m} \cdot \text{K}} \frac{(50 - 40)^{\circ}\text{C}}{(20 - 10) \times 10^{-3} \text{m}} = 15,000 \text{ W/m}^2.$$

Since the temperature gradient in the solid must be linear for the prescribed conditions, it follows that

$$T_0 = 60^{\circ}\text{C}.$$

Hence, the convection coefficient is

$$h = \frac{q''_{\text{cond}}}{T_{\infty} - T_0}$$

$$h = \frac{15,000 \text{ W/m}^2}{40^{\circ}\text{C}} = 375 \text{ W/m}^2 \cdot \text{K}.$$

<

COMMENTS: The accuracy of this procedure for measuring h depends strongly on the validity of the assumed conditions.

PROBLEM 1.62

KNOWN: Duct wall of prescribed thickness and thermal conductivity experiences prescribed heat flux q''_o at outer surface and convection at inner surface with known heat transfer coefficient.

FIND: (a) Heat flux at outer surface required to maintain inner surface of duct at $T_i = 85^\circ\text{C}$, (b) Temperature of outer surface, T_o , (c) Effect of h on T_o and q''_o .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in wall, (3) Constant properties, (4) Backside of heater perfectly insulated, (5) Negligible radiation.

ANALYSIS: (a) By performing an energy balance on the wall, recognize that $q''_o = q''_{\text{cond}}$. From an energy balance on the top surface, it follows that $q''_{\text{cond}} = q''_{\text{conv}} = q''_o$. Hence, using the convection rate equation,

$$q''_o = q''_{\text{conv}} = h(T_i - T_\infty) = 100 \text{ W/m}^2\cdot\text{K}(85 - 30)^\circ\text{C} = 5500 \text{ W/m}^2. \quad <$$

(b) Considering the duct wall and applying Fourier's Law,

$$q''_o = k \frac{\Delta T}{\Delta x} = k \frac{T_o - T_i}{L}$$

$$T_o = T_i + \frac{q''_o L}{k} = 85^\circ\text{C} + \frac{5500 \text{ W/m}^2 \times 0.010 \text{ m}}{20 \text{ W/m}\cdot\text{K}} = (85 + 2.8)^\circ\text{C} = 87.8^\circ\text{C}. \quad <$$

(c) For $T_i = 85^\circ\text{C}$, the desired results may be obtained by simultaneously solving the energy balance equations

$$q''_o = k \frac{T_o - T_i}{L} \quad \text{and} \quad k \frac{T_o - T_i}{L} = h(T_i - T_\infty)$$

Using the IHT First Law Model for a *Nonisothermal Plane Wall*, the following results are obtained.

Since q''_{conv} increases linearly with increasing h , the applied heat flux q''_o and q''_{cond} must also increase. An increase in q''_{cond} , which, with fixed k , T_i and L , necessitates an increase in T_o .

COMMENTS: The temperature difference across the wall is small, amounting to a maximum value of $(T_o - T_i) = 5.5^\circ\text{C}$ for $h = 200 \text{ W/m}^2\cdot\text{K}$. If the wall were thinner ($L < 10 \text{ mm}$) or made from a material with higher conductivity ($k > 20 \text{ W/m}\cdot\text{K}$), this difference would be reduced.

PROBLEM 1.63

KNOWN: Dimensions, average surface temperature and emissivity of heating duct. Duct air inlet temperature and velocity. Temperature of ambient air and surroundings. Convection coefficient.

FIND: (a) Heat loss from duct, (b) Air outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant air properties, (3) Negligible potential and kinetic energy changes of air flow, (4) Radiation exchange between a small surface and a large enclosure.

ANALYSIS: (a) Heat transfer from the surface of the duct to the ambient air and the surroundings is given by Eq. (1.10)

$$q = hA_s(T_s - T_\infty) + \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4)$$

where $A_s = L(2W + 2H) = 15 \text{ m}(0.7 \text{ m} + 0.5 \text{ m}) = 16.5 \text{ m}^2$. Hence,

$$q = 4 \text{ W/m}^2 \cdot \text{K} \times 16.5 \text{ m}^2 (45^\circ\text{C}) + 0.5 \times 16.5 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (323^4 - 278^4) \text{ K}^4$$

$$q = q_{\text{conv}} + q_{\text{rad}} = 2970 \text{ W} + 2298 \text{ W} = 5268 \text{ W} \quad <$$

(b) With $i = u + pv$, $\dot{W} = 0$ and the third assumption, Eq. (1.11d) yields,

$$\dot{m}(i_i - i_o) = \dot{m}c_p(T_i - T_o) = q$$

where the sign on q has been reversed to reflect the fact that heat transfer is *from* the system.

With $\dot{m} = \rho VA_c = 1.10 \text{ kg/m}^3 \times 4 \text{ m/s} (0.35 \text{ m} \times 0.20 \text{ m}) = 0.308 \text{ kg/s}$, the outlet temperature is

$$T_o = T_i - \frac{q}{\dot{m}c_p} = 58^\circ\text{C} - \frac{5268 \text{ W}}{0.308 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K}} = 41^\circ\text{C} \quad <$$

COMMENTS: The temperature drop of the air is large and unacceptable, unless the intent is to use the duct to heat the basement. If not, the duct should be insulated to insure maximum delivery of thermal energy to the intended space(s).

PROBLEM 1.64

KNOWN: Uninsulated pipe of prescribed diameter, emissivity, and surface temperature in a room with fixed wall and air temperatures. See Example 1.2.

FIND: (a) Which option to reduce heat loss to the room is more effective: reduce by a factor of two the convection coefficient (from 15 to 7.5 W/m²·K) or the emissivity (from 0.8 to 0.4) and (b) Show graphically the heat loss as a function of the convection coefficient for the range 5 ≤ h ≤ 20 W/m²·K for emissivities of 0.2, 0.4 and 0.8. Comment on the relative efficacy of reducing heat losses associated with the convection and radiation processes.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Radiation exchange between pipe and the room is between a small surface in a much larger enclosure, (3) The surface emissivity and absorptivity are equal, and (4) Restriction of the air flow does not alter the radiation exchange process between the pipe and the room.

ANALYSIS: (a) The heat rate from the pipe to the room per unit length is

$$q' = q'/L = q'_{\text{conv}} + q'_{\text{rad}} = h(\pi D)(T_s - T_\infty) + \varepsilon(\pi D)\sigma(T_s^4 - T_{\text{sur}}^4)$$

Substituting numerical values for the two options, the resulting heat rates are calculated and compared with those for the conditions of Example 1.2. We conclude that both options are comparably effective.

Conditions	h (W/m ² ·K)	ε	q' (W/m)
Base case, Example 1.2	15	0.8	998
Reducing h by factor of 2	7.5	0.8	788
Reducing ε by factor of 2	15	0.4	709

(b) Using IHT, the heat loss can be calculated as a function of the convection coefficient for selected values of the surface emissivity.

Continued

PROBLEM 1.64 (Cont.)

COMMENTS: (1) In Example 1.2, Comment 3, we read that the heat rates by convection and radiation exchange were comparable for the base case conditions (577 vs. 421 W/m). It follows that reducing the key transport parameter (h or ϵ) by a factor of two yields comparable reductions in the heat loss. Coating the pipe to reduce the emissivity might be the more practical option as it may be difficult to control air movement.

(2) For this pipe size and thermal conditions (T_s and T_∞), the minimum possible convection coefficient is approximately $7.5 \text{ W/m}^2 \cdot \text{K}$, corresponding to free convection heat transfer to quiescent ambient air. Larger values of h are a consequence of forced air flow conditions.

(3) The Workspace for the IHT program to calculate the heat loss and generate the graph for the heat loss as a function of the convection coefficient for selected emissivities is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results.

```
// Heat loss per unit pipe length; rate equation from Ex. 1.2
q' = q'cv + q'rad
q'cv = pi*D*h*(Ts - Tinf)
q'rad = pi*D*eps*sigma*(Ts^4 - Tsur^4)
sigma = 5.67e-8

// Input parameters
D = 0.07
Ts_C = 200      // Representing temperatures in Celsius units using _C subscripting
Ts = Ts_C + 273
Tinf_C = 25
Tinf = Tinf_C + 273
h = 15          // For graph, sweep over range from 5 to 20
Tsur_C = 25
Tsur = Tsur_C + 273
eps = 0.8
//eps = 0.4     // Values of emissivity for parameter study
//eps = 0.2

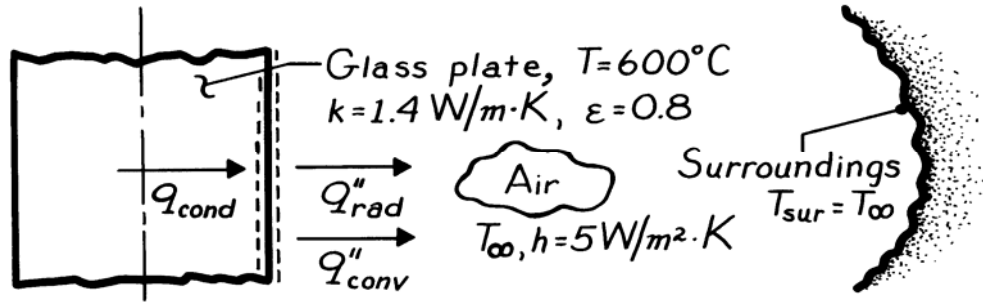

/* Base case results

```

PROBLEM 1.65

KNOWN: Conditions associated with surface cooling of plate glass which is initially at 600°C. Maximum allowable temperature gradient in the glass.

FIND: Lowest allowable air temperature, T_∞

SCHEMATIC:

ASSUMPTIONS: (1) Surface of glass exchanges radiation with large surroundings at $T_{\text{sur}} = T_\infty$, (2) One-dimensional conduction in the x -direction.

ANALYSIS: The maximum temperature gradient will exist at the surface of the glass and at the instant that cooling is initiated. From the surface energy balance, Eq. 1.12, and the rate equations, Eqs. 1.1, 1.3a and 1.7, it follows that

$$-k \frac{dT}{dx} - h(T_s - T_\infty) - \epsilon \sigma (T_s^4 - T_{\text{sur}}^4) = 0$$

or, with $(dT/dx)_{\text{max}} = -15^\circ\text{C/mm} = -15,000^\circ\text{C/m}$ and $T_{\text{sur}} = T_\infty$,

$$\begin{aligned} -1.4 \frac{\text{W}}{\text{m} \cdot \text{K}} \left[-15,000 \frac{^\circ\text{C}}{\text{m}} \right] &= 5 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (873 - T_\infty) \text{K} \\ &+ 0.8 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} [873^4 - T_\infty^4] \text{K}^4. \end{aligned}$$

T_∞ may be obtained from a trial-and-error solution, from which it follows that, for $T_\infty = 618\text{K}$,

$$21,000 \frac{\text{W}}{\text{m}^2} \approx 1275 \frac{\text{W}}{\text{m}^2} + 19,730 \frac{\text{W}}{\text{m}^2}.$$

Hence the lowest allowable air temperature is

$$T_\infty \approx 618\text{K} = 345^\circ\text{C}.$$

<

COMMENTS: (1) Initially, cooling is determined primarily by radiation effects.

(2) For fixed T_∞ , the surface *temperature gradient* would *decrease* with *increasing* time into the cooling process. Accordingly, T_∞ could be decreasing with increasing time and still keep within the maximum allowable temperature gradient.

PROBLEM 1.66

KNOWN: Hot-wall oven, in lieu of infrared lamps, with temperature $T_{\text{sur}} = 200^\circ\text{C}$ for heating a coated plate to the cure temperature. See Example 1.7.

FIND: (a) The plate temperature T_s for prescribed convection conditions and coating emissivity, and (b) Calculate and plot T_s as a function of T_{sur} for the range $150 \leq T_{\text{sur}} \leq 250^\circ\text{C}$ for ambient air temperatures of 20, 40 and 60°C ; identify conditions for which acceptable curing temperatures between 100 and 110°C may be maintained.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss from back surface of plate, (3) Plate is small object in large isothermal surroundings (hot oven walls).

ANALYSIS: (a) The temperature of the plate can be determined from an energy balance on the plate, considering radiation exchange with the hot oven walls and convection with the ambient air.

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' = 0 \quad \text{or} \quad q''_{\text{rad}} - q''_{\text{conv}} = 0$$

$$\varepsilon\sigma(T_{\text{sur}}^4 - T_s^4) - h(T_s - T_\infty) = 0$$

$$0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left([200 + 273]^4 - T_s^4 \right) \text{ K}^4 - 15 \text{ W/m}^2 \cdot \text{K} (T_s - [20 + 273]) \text{ K} = 0$$

$$T_s = 357 \text{ K} = 84^\circ\text{C}$$

<

(b) Using the energy balance relation in the Workspace of IHT, the plate temperature can be calculated and plotted as a function of oven wall temperature for selected ambient air temperatures.

COMMENTS: From the graph, acceptable cure temperatures between 100 and 110°C can be maintained for these conditions: with $T_\infty = 20^\circ\text{C}$ when $225 \leq T_{\text{sur}} \leq 240^\circ\text{C}$; with $T_\infty = 40^\circ\text{C}$ when $205 \leq T_{\text{sur}} \leq 220^\circ\text{C}$; and with $T_\infty = 60^\circ\text{C}$ when $175 \leq T_{\text{sur}} \leq 195^\circ\text{C}$.

PROBLEM 1.67

KNOWN: Operating conditions for an electrical-substitution radiometer having the same receiver temperature, T_s , in electrical and optical modes.

FIND: Optical power of a laser beam and corresponding receiver temperature when the indicated electrical power is 20.64 mW.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Conduction losses from backside of receiver negligible in optical mode, (3) Chamber walls form large isothermal surroundings; negligible effects due to aperture, (4) Radiation exchange between the receiver surface and the chamber walls is between small surface and large enclosure, (5) Negligible convection effects.

PROPERTIES: Receiver surface: $\varepsilon = 0.95$, $\alpha_{\text{opt}} = 0.98$.

ANALYSIS: The schematic represents the operating conditions for the *electrical mode* with the optical beam blocked. The temperature of the receiver surface can be found from an energy balance on the receiver, considering the electrical power input, conduction loss from the backside of the receiver, and the radiation exchange between the receiver and the chamber.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$P_{\text{elec}} - q_{\text{loss}} - q_{\text{rad}} = 0$$

$$P_{\text{elec}} - 0.05 P_{\text{elec}} - \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4) = 0$$

$$20.64 \times 10^{-3} \text{ W} (1 - 0.05) - 0.95 \left(\pi (0.015)^2 / 4 \right) \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_s^4 - 77^4) \text{ K}^4 = 0$$

$$T_s = 213.9 \text{ K}$$

<

For the *optical mode* of operation, the optical beam is incident on the receiver surface, there is no electrical power input, and the receiver temperature is the same as for the electrical mode. The optical power of the beam can be found from an energy balance on the receiver considering the absorbed beam power and radiation exchange between the receiver and the chamber.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$\alpha_{\text{opt}} P_{\text{opt}} - q_{\text{rad}} = 0.98 P_{\text{opt}} - 19.60 \text{ mW} = 0$$

$$P_{\text{opt}} = 19.99 \text{ mW}$$

<

where q_{rad} follows from the previous energy balance using $T_s = 213.9 \text{ K}$.

COMMENTS: Recognizing that the receiver temperature, and hence the radiation exchange, is the same for both modes, an energy balance could be directly written in terms of the absorbed optical power and equivalent electrical power, $\alpha_{\text{opt}} P_{\text{opt}} = P_{\text{elec}} - q_{\text{loss}}$.

PROBLEM 1.68

KNOWN: Surface temperature, diameter and emissivity of a hot plate. Temperature of surroundings and ambient air. Expression for convection coefficient.

FIND: (a) Operating power for prescribed surface temperature, (b) Effect of surface temperature on power requirement and on the relative contributions of radiation and convection to heat transfer from the surface.

SCHEMATIC:

ASSUMPTIONS: (1) Plate is of uniform surface temperature, (2) Walls of room are large relative to plate, (3) Negligible heat loss from bottom or sides of plate.

ANALYSIS: (a) From an energy balance on the hot plate, $P_{elec} = q_{conv} + q_{rad} = A_p (q''_{conv} + q''_{rad})$.

Substituting for the area of the plate and from Eqs. (1.3a) and (1.7), with $h = 0.80 (T_s - T_{\infty})^{1/3}$, it follows that

$$P_{elec} = \left(\pi D^2 / 4 \right) \left[0.80 (T_s - T_{\infty})^{4/3} + \varepsilon \sigma (T_s^4 - T_{sur}^4) \right]$$

$$P_{elec} = \pi (0.3 \text{ m})^2 / 4 \left[0.80 (175)^{4/3} + 0.8 \times 5.67 \times 10^{-8} (473^4 - 298^4) \right] \text{ W/m}^2$$

$$P_{elec} = 0.0707 \text{ m}^2 \left[783 \text{ W/m}^2 + 1913 \text{ W/m}^2 \right] = 55.4 \text{ W} + 135.2 \text{ W} = 190.6 \text{ W} \quad <$$

(b) As shown graphically, both the radiation and convection heat rates, and hence the requisite electric power, increase with increasing surface temperature.

However, because of its dependence on the fourth power of the surface temperature, the increase in radiation is more pronounced. The significant relative effect of radiation is due to the small convection coefficients characteristic of natural convection, with $3.37 \leq h \leq 5.2 \text{ W/m}^2 \cdot \text{K}$ for $100 \leq T_s < 300^\circ\text{C}$.

COMMENTS: Radiation losses could be reduced by applying a low emissivity coating to the surface, which would have to maintain its integrity over the range of operating temperatures.

PROBLEM 1.69

KNOWN: Long bus bar of rectangular cross-section and ambient air and surroundings temperatures. Relation for the electrical resistivity as a function of temperature.

FIND: (a) Temperature of the bar with a current of 60,000 A, and (b) Compute and plot the operating temperature of the bus bar as a function of the convection coefficient for the range $10 \leq h \leq 100$ $\text{W/m}^2 \cdot \text{K}$. Minimum convection coefficient required to maintain a safe-operating temperature below 120°C . Will increasing the emissivity significantly affect this result?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Bus bar is long, (3) Uniform bus-bar temperature, (3) Radiation exchange between the outer surface of the bus bar and its surroundings is between a small surface and a large enclosure.

PROPERTIES: Bus-bar material, $\rho_e = \rho_{e,o} [1 + \alpha (T - T_o)]$, $\rho_{e,o} = 0.0828 \mu\Omega \cdot \text{m}$, $T_o = 25^\circ\text{C}$, $\alpha = 0.0040 \text{ K}^{-1}$.

ANALYSIS: (a) An energy balance on the bus-bar for a unit length as shown in the schematic above has the form

$$\begin{aligned} \dot{E}'_{\text{in}} - \dot{E}'_{\text{out}} + \dot{E}'_{\text{gen}} &= 0 & -q'_{\text{rad}} - q'_{\text{conv}} + I^2 R'_e &= 0 \\ -\epsilon P \sigma (T^4 - T_{\text{sur}}^4) - h P (T - T_\infty) + I^2 \rho_e / A_c &= 0 \end{aligned}$$

where $P = 2(H + W)$, $R'_e = \rho_e / A_c$ and $A_c = H \times W$. Substituting numerical values,

$$\begin{aligned} &-0.8 \times 2(0.600 + 0.200) \text{ m} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T^4 - [30 + 273]^4) \text{ K}^4 \\ &-10 \text{ W/m}^2 \cdot \text{K} \times 2(0.600 + 0.200) \text{ m} (T - [30 + 273]) \text{ K} \\ &+ (60,000 \text{ A})^2 \left\{ 0.0828 \times 10^{-6} \Omega \cdot \text{m} \left[1 + 0.0040 \text{ K}^{-1} (T - [25 + 273]) \text{ K} \right] \right\} / (0.600 \times 0.200) \text{ m}^2 = 0 \end{aligned}$$

Solving for the bus-bar temperature, find $T = 426 \text{ K} = 153^\circ\text{C}$. <

(b) Using the energy balance relation in the Workspace of IHT, the bus-bar operating temperature is calculated as a function of the convection coefficient for the range $10 \leq h \leq 100 \text{ W/m}^2 \cdot \text{K}$. From this graph we can determine that to maintain a safe operating temperature below 120°C , the minimum convection coefficient required is

$$h_{\text{min}} = 16 \text{ W/m}^2 \cdot \text{K}. <$$

Continued

PROBLEM 1.69 (Cont.)

Using the same equations, we can calculate and plot the heat transfer rates by convection and radiation as a function of the bus-bar temperature.

Note that convection is the dominant mode for low bus-bar temperatures; that is, for low current flow. As the bus-bar temperature increases toward the safe-operating limit (120°C), convection and radiation exchange heat transfer rates become comparable. Notice that the relative importance of the radiation exchange rate increases with increasing bus-bar temperature.

COMMENTS: (1) It follows from the second graph that increasing the surface emissivity will be only significant at higher temperatures, especially beyond the safe-operating limit.

(2) The Workspace for the IHT program to perform the parametric analysis and generate the graphs is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results.

/* Results for base case conditions:

PROBLEM 1.70

KNOWN: Solar collector designed to heat water operating under prescribed solar irradiation and loss conditions.

FIND: (a) Useful heat collected per unit area of the collector, q_u'' , (b) Temperature rise of the water flow, $T_o - T_i$, and (c) Collector efficiency.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) No heat losses out sides or back of collector, (3) Collector area is small compared to sky surroundings.

PROPERTIES: Table A.6, Water (300K): $c_p = 4179 \text{ J/kg} \cdot \text{K}$.

ANALYSIS: (a) Defining the collector as the control volume and writing the conservation of energy requirement on a per unit area basis, find that

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = \dot{E}_{\text{st}}.$$

Identifying processes as per above right sketch,

$$q_{\text{solar}}'' - q_{\text{rad}}'' - q_{\text{conv}}'' - q_u'' = 0$$

where $q_{\text{solar}}'' = 0.9 q_s''$; that is, 90% of the solar flux is absorbed in the collector (Eq. 1.6). Using the appropriate rate equations, the useful heat rate per unit area is

$$\begin{aligned} q_u'' &= 0.9 q_s'' - \varepsilon \sigma (T_{\text{cp}}^4 - T_{\text{sky}}^4) - h(T_s - T_{\infty}) \\ q_u'' &= 0.9 \times 700 \frac{\text{W}}{\text{m}^2} - 0.94 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} (303^4 - 263^4) \text{K}^4 - 10 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (30 - 25)^\circ \text{C} \\ q_u'' &= 630 \text{ W/m}^2 - 194 \text{ W/m}^2 - 50 \text{ W/m}^2 = 386 \text{ W/m}^2. \end{aligned} \quad <$$

(b) The total useful heat collected is $q_u'' \cdot A$. Defining a control volume about the water tubing, the useful heat causes an enthalpy change of the flowing water. That is,

$$q_u'' \cdot A = \dot{m} c_p (T_i - T_o) \quad \text{or}$$

$$(T_i - T_o) = 386 \text{ W/m}^2 \times 3 \text{ m}^2 / 0.01 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} = 27.7^\circ \text{C}. \quad <$$

(c) The efficiency is $\eta = q_u'' / q_s'' = (386 \text{ W/m}^2) / (700 \text{ W/m}^2) = 0.55$ or 55%. <

COMMENTS: Note how the sky has been treated as large surroundings at a uniform temperature T_{sky} .

PROBLEM 1.71

KNOWN: Surface-mount transistor with prescribed dissipation and convection cooling conditions.

FIND: (a) Case temperature for mounting arrangement with air-gap and conductive paste between case and circuit board, (b) Consider options for increasing \dot{E}_g , subject to the constraint that $T_c = 40^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Transistor case is isothermal, (3) Upper surface experiences convection; negligible losses from edges, (4) Leads provide conduction path between case and board, (5) Negligible radiation, (6) Negligible energy generation in leads due to current flow, (7) Negligible convection from surface of leads.

PROPERTIES: (Given): Air, $k_{g,a} = 0.0263 \text{ W/m}\cdot\text{K}$; Paste, $k_{g,p} = 0.12 \text{ W/m}\cdot\text{K}$; Metal leads, $k_\ell = 25 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) Define the transistor as the system and identify modes of heat transfer.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = \Delta \dot{E}_{\text{st}} = 0$$

$$-q_{\text{conv}} - q_{\text{cond,gap}} - 3q_{\text{lead}} + \dot{E}_g = 0$$

$$-hA_s(T_c - T_\infty) - k_g A_s \frac{T_c - T_b}{t} - 3k_\ell A_c \frac{T_c - T_b}{L} + \dot{E}_g = 0$$

where $A_s = L_1 \times L_2 = 4 \times 8 \text{ mm}^2 = 32 \times 10^{-6} \text{ m}^2$ and $A_c = t \times w = 0.25 \times 1 \text{ mm}^2 = 25 \times 10^{-8} \text{ m}^2$.

Rearranging and solving for T_c ,

$$T_c = \left\{ hA_s T_\infty + \left[k_g A_s / t + 3(k_\ell A_c / L) \right] T_b + \dot{E}_g \right\} / \left[hA_s + k_g A_s / t + 3 k_\ell A_c / L \right]$$

Substituting numerical values, with the *air-gap condition* ($k_{g,a} = 0.0263 \text{ W/m}\cdot\text{K}$)

$$T_c = \left\{ 50 \text{ W/m}^2 \cdot \text{K} \times 32 \times 10^{-6} \text{ m}^2 \times 20^\circ\text{C} + \left[(0.0263 \text{ W/m}\cdot\text{K} \times 32 \times 10^{-6} \text{ m}^2 / 0.2 \times 10^{-3} \text{ m}) + 3(25 \text{ W/m}\cdot\text{K} \times 25 \times 10^{-8} \text{ m}^2 / 4 \times 10^{-3} \text{ m}) \right] 35^\circ\text{C} \right\} / \left[1.600 \times 10^{-3} + 4.208 \times 10^{-3} + 4.688 \times 10^{-3} \right] \text{ W/K}$$

$$T_c = 47.0^\circ\text{C}.$$

<

Continued.....

PROBLEM 1.71 (Cont.)

With the *paste condition* ($k_{g,p} = 0.12 \text{ W/m}\cdot\text{K}$), $T_C = 39.9^\circ\text{C}$. As expected, the effect of the conductive paste is to improve the coupling between the circuit board and the case. Hence, T_C decreases.

(b) Using the keyboard to enter model equations into the workspace, IHT has been used to perform the desired calculations. For values of $k_\ell = 200$ and $400 \text{ W/m}\cdot\text{K}$ and convection coefficients in the range from 50 to $250 \text{ W/m}^2\cdot\text{K}$, the energy balance equation may be used to compute the power dissipation for a maximum allowable case temperature of 40°C .

As indicated by the energy balance, the power dissipation increases linearly with increasing h , as well as with increasing k_ℓ . For $h = 250 \text{ W/m}^2\cdot\text{K}$ (enhanced air cooling) and $k_\ell = 400 \text{ W/m}\cdot\text{K}$ (copper leads), the transistor may dissipate up to 0.63 W .

COMMENTS: Additional benefits may be derived by increasing heat transfer across the gap separating the case from the board, perhaps by inserting a highly conductive material in the gap.

PROBLEM 1.72(a)

KNOWN: Solar radiation is incident on an asphalt paving.

FIND: Relevant heat transfer processes.

SCHEMATIC:

The relevant processes shown on the schematic include:

- q_s'' Incident solar radiation, a large portion of which $q_{s,abs}''$, is absorbed by the asphalt surface,
- q_{rad}'' Radiation emitted by the surface to the air,
- q_{conv}'' Convection heat transfer from the surface to the air, and
- q_{cond}'' Conduction heat transfer from the surface into the asphalt.

Applying the surface energy balance, Eq. 1.12,

$$q_{s,abs}'' - q_{rad}'' - q_{conv}'' = q_{cond}''.$$

COMMENTS: (1) q_{cond}'' and q_{conv}'' could be evaluated from Eqs. 1.1 and 1.3, respectively.

- (2) It has been assumed that the pavement surface temperature is higher than that of the underlying pavement and the air, in which case heat transfer by conduction and convection are from the surface.
- (3) For simplicity, radiation incident on the pavement due to atmospheric emission has been ignored (see Section 12.8 for a discussion). Eq. 1.6 may then be used for the absorbed solar irradiation and Eq. 1.5 may be used to obtain the emitted radiation q_{rad}'' .
- (4) With the rate equations, the energy balance becomes

$$q_{s,abs}'' - \varepsilon \sigma T_s^4 - h(T_s - T_\infty) = -k \left. \frac{dT}{dx} \right|_s.$$

PROBLEM 1.72(b)

KNOWN: Physical mechanism for microwave heating.

FIND: Comparison of (a) cooking in a microwave oven with a conventional radiant or convection oven and (b) a microwave clothes dryer with a conventional dryer.

(a) Microwave cooking occurs as a result of volumetric thermal energy generation *throughout* the food, without heating of the food container or the oven wall. Conventional cooking relies on radiant heat transfer from the oven walls and/or convection heat transfer from the air space to the surface of the food and subsequent heat transfer by conduction to the core of the food. Microwave cooking is more efficient and is achieved in less time.

(b) In a microwave dryer, the microwave radiation would heat the water, but not the fabric, directly (the fabric would be heated indirectly by energy transfer from the water). By heating the water, energy would go directly into evaporation, unlike a conventional dryer where the walls and air are first heated electrically or by a gas heater, and thermal energy is subsequently transferred to the wet clothes. The microwave dryer would still require a rotating drum and air flow to remove the water vapor, but is able to operate more efficiently and at lower temperatures. For a more detailed description of microwave drying, see *Mechanical Engineering*, March 1993, page 120.

PROBLEM 1.72 (c)

KNOWN: Water storage tank initial temperature, water initial pressure and temperature, storage tank configuration.

FIND: Identify heat transfer processes that will promote freezing of water. Determine effect of insulation thickness. Determine effect of wall thickness and tank material. Determine effect of transfer tubing material. Discuss optimal tank shape, and effect of applying thin aluminum foil to the outside of the tank.

SCHEMATIC:

Figure 1 Rapid Response.

Figure 2 Slow Response.

ANALYSIS: The thermal response of the water may be analyzed by dividing the cooling process into two parts.

Part One. Water and Tank Rapid Response.

We expect the mass of water to be significantly greater than the mass of the tank. From experience, we would not expect the water to completely freeze immediately after filling the tank. Assuming negligible heat transfer through the insulation or transfer tubing during this initial rapid water cooling period, no heat transfer to the air above the water, and assuming isothermal water and tank behavior at any instant in time, an energy balance on a control volume surrounding the water would yield

$$\dot{E}_{st,w} = -\dot{E}_{out,w} \quad (1)$$

An energy balance on a control volume surrounding the tank would yield

$$\dot{E}_{in,t} = \dot{E}_{st,t} \quad (2)$$

$$\text{where } \dot{E}_{out,w} = \dot{E}_{in,t} \quad (3)$$

Combining Eqs. (1) – (3) yields

Continued...

PROBLEM 1.72 (c) (Cont.)

$$\dot{E}_{st,w} = -\dot{E}_{st,t} = M_w c_{p,w} \cdot (\bar{T} - T_{i,w}) = M_t c_{p,t} \cdot (T_{i,t} - \bar{T}) \quad (4)$$

where \bar{T} is the average temperature of the water and tank after the initial filling process. For $M_w c_{p,w} \gg M_t c_{p,t}$, $\bar{T} \approx T_{i,w}$, thus confirming our expectation.

Part Two. Slow Water Cooling.

The heat transfer processes that would promote water freezing include:

- heat transfer through the insulation to the cold air
- heat loss by conduction upward through the wall of the transfer tubing <

As the insulation thickness, t_{ins} , is increased, Fourier's law indicates that heat losses from the water are decreased, slowing the rate at which the water cools. <

As the tank wall thickness, t_t , is increased, the tank wall mass increases. This, along with increasing the tank wall specific heat, will serve to reduce the average temperature, \bar{T} , to a lower value, as evident by inspecting Eq. (4). This effect, based on the first law of thermodynamics, would decrease the time needed to cool the water to the freezing temperature. As the tank wall thickness is increased, however, heat losses by conduction through the tank wall would decrease as seen by inspection of Fourier's law, slowing the cooling process. As the tank wall thermal conductivity is reduced, this will also decrease the cooling rate of the water. Therefore, the effect of the tank wall thickness could increase *or* decrease the water cooling rate. As the thermal conductivity of the transfer tubing is increased, heat losses from the water upward through the tube wall will increase. This suggests that use of plastic for the transfer tubing would slow the cooling of the water. <

To slow the cooling process, a large water mass to surface area is desired. The mass is proportional to the volume of water in the tank, while the heat loss from the tank by convection to the cold air and radiation to the surroundings is proportional to the surface area of the tank. A spherical tank maximizes the volume-to-area ratio, reducing the rate at which the water temperature drops, and would help prevent freezing. <

Heat losses will occur by convection and radiation at the exposed tank area. The radiation loss, according to Eq. 1.7, is proportional to the emissivity of the surface. Aluminum foil is a low emissivity material, and therefore a wrap of foil would slow the water cooling process. The aluminum foil is very thin and has a high thermal conductivity, therefore by Fourier's law, there would be a very small temperature drop across the thickness of the foil and would not impact the cooling rate. <

PROBLEM 1.72(d)

KNOWN: Tungsten filament is heated to 2900 K in an air-filled glass bulb.

FIND: Relevant heat transfer processes.

SCHEMATIC:

The relevant processes associated with the filament and bulb include:

- $q_{rad,f}$ Radiation emitted by the tungsten filament, a portion of which is transmitted through the glass,
- $q_{conv,f}$ Free convection from filament to air of temperature $T_{a,i} < T_f$,
- $q_{rad,g,i}$ Radiation emitted by inner surface of glass, a small portion of which is intercepted by the filament,
- $q_{conv,g,i}$ Free convection from air to inner glass surface of temperature $T_{g,i} < T_{a,i}$,
- $q_{cond,g}$ Conduction through glass wall,
- $q_{conv,g,o}$ Free convection from outer glass surface to room air of temperature $T_{a,o} < T_{g,o}$, and
- $q_{rad,g-sur}$ Net radiation heat transfer between outer glass surface and surroundings, such as the walls of a room, of temperature $T_{sur} < T_{g,o}$.

COMMENTS: If the glass bulb is evacuated, no convection is present within the bulb; that is, $q_{conv,f} = q_{conv,g,i} = 0$.

PROBLEM 1.72(e)

KNOWN: Geometry of a composite insulation consisting of a honeycomb core.

FIND: Relevant heat transfer processes.

SCHEMATIC:

The above schematic represents the cross section of a single honeycomb cell and surface slabs. Assumed direction of gravity field is downward. Assuming that the bottom (inner) surface temperature exceeds the top (outer) surface temperature ($T_{s,i} > T_{s,o}$), heat transfer is in the direction shown.

Heat may be transferred to the inner surface by convection and radiation, whereupon it is transferred through the composite by

- $q_{cond,i}$ Conduction through the inner solid slab,
- $q_{conv,hc}$ Free convection through the cellular airspace,
- $q_{cond,hc}$ Conduction through the honeycomb wall,
- $q_{rad,hc}$ Radiation between the honeycomb surfaces, and
- $q_{cond,o}$ Conduction through the outer solid slab.

Heat may then be transferred from the outer surface by convection and radiation. Note that for a single cell under steady state conditions,

$$q_{rad,i} + q_{conv,i} = q_{cond,i} = q_{conv,hc} + q_{cond,hc}$$

$$+q_{rad,hc} = q_{cond,o} = q_{rad,o} + q_{conv,o}$$

COMMENTS: Performance would be enhanced by using materials of low thermal conductivity, k , and emissivity, ϵ . Evacuating the airspace would enhance performance by eliminating heat transfer due to free convection.

PROBLEM 1.72(f)

KNOWN: A thermocouple junction is used, with or without a radiation shield, to measure the temperature of a gas flowing through a channel. The wall of the channel is at a temperature much less than that of the gas.

FIND: (a) Relevant heat transfer processes, (b) Temperature of junction relative to that of gas, (c) Effect of radiation shield.

SCHEMATIC:

ASSUMPTIONS: (1) Junction is small relative to channel walls, (2) Steady-state conditions, (3) Negligible heat transfer by conduction through the thermocouple leads.

ANALYSIS: (a) The relevant heat transfer processes are:

q_{rad} Net radiation transfer from the junction to the walls, and

q_{conv} Convection transfer from the gas to the junction.

(b) From a surface energy balance on the junction,

$$q_{conv} = q_{rad}$$

or from Eqs. 1.3a and 1.7,

$$h A (T_g - T_j) = \varepsilon A \sigma (T_j^4 - T_s^4).$$

To satisfy this equality, it follows that

$$T_s < T_j < T_g.$$

That is, the junction assumes a temperature between that of the channel wall and the gas, thereby sensing a temperature which is less than that of the gas.

(c) The measurement error $(T_g - T_j)$ is reduced by using a radiation shield as shown in the schematic. The junction now exchanges radiation with the shield, whose temperature must exceed that of the channel wall. The radiation loss from the junction is therefore reduced, and its temperature more closely approaches that of the gas.

PROBLEM 1.72(g)

KNOWN: Fireplace cavity is separated from room air by two glass plates, open at both ends.

FIND: Relevant heat transfer processes.

SCHEMATIC:

The relevant heat transfer processes associated with the double-glazed, glass fire screen are:

- | | |
|--------------|---|
| $q_{rad,1}$ | Radiation from flames and cavity wall, portions of which are absorbed and transmitted by the two panes, |
| $q_{rad,2}$ | Emission from inner surface of inner pane to cavity, |
| $q_{rad,3}$ | Net radiation exchange between outer surface of inner pane and inner surface of outer pane, |
| $q_{rad,4}$ | Net radiation exchange between outer surface of outer pane and walls of room, |
| $q_{conv,1}$ | Convection between cavity gases and inner pane, |
| $q_{conv,2}$ | Convection across air space between panes, |
| $q_{conv,3}$ | Convection from outer surface to room air, |
| $q_{cond,1}$ | Conduction across inner pane, and |
| $q_{cond,2}$ | Conduction across outer pane. |

COMMENTS: (1) Much of the luminous portion of the flame radiation is transmitted to the room interior.

(2) All convection processes are buoyancy driven (free convection).

PROBLEM 1.73(a)

KNOWN: Room air is separated from ambient air by one or two glass panes.

FIND: Relevant heat transfer processes.

SCHEMATIC:

The relevant processes associated with single (above left schematic) and double (above right schematic) glass panes include.

- $q_{conv,1}$ Convection from room air to inner surface of first pane,
- $q_{rad,1}$ Net radiation exchange between room walls and inner surface of first pane,
- $q_{cond,1}$ Conduction through first pane,
- $q_{conv,s}$ Convection across airspace between panes,
- $q_{rad,s}$ Net radiation exchange between outer surface of first pane and inner surface of second pane (across airspace),
- $q_{cond,2}$ Conduction through a second pane,
- $q_{conv,2}$ Convection from outer surface of single (or second) pane to ambient air,
- $q_{rad,2}$ Net radiation exchange between outer surface of single (or second) pane and surroundings such as the ground, and
- q_s Incident solar radiation during day; fraction transmitted to room is smaller for double pane.

COMMENTS: Heat loss from the room is significantly reduced by the double pane construction.

PROBLEM 1.73(b)

KNOWN: Configuration of a flat plate solar collector.

FIND: Relevant heat transfer processes with and without a cover plate.

SCHEMATIC:

The relevant processes without (above left schematic) and with (above right schematic) include:

- q_s Incident solar radiation, a large portion of which is absorbed by the absorber plate. Reduced with use of cover plate (primarily due to reflection off cover plate).
- $q_{rad,\infty}$ Net radiation exchange between absorber plate or cover plate and surroundings,
- $q_{conv,\infty}$ Convection from absorber plate or cover plate to ambient air,
- $q_{rad,a-c}$ Net radiation exchange between absorber and cover plates,
- $q_{conv,a-c}$ Convection heat transfer across airspace between absorber and cover plates,
- q_{cond} Conduction through insulation, and
- q_{conv} Convection to working fluid.

COMMENTS: The cover plate acts to significantly reduce heat losses by convection and radiation from the absorber plate to the surroundings.

PROBLEM 1.73(c)

KNOWN: Configuration of a solar collector used to heat air for agricultural applications.

FIND: Relevant heat transfer processes.

SCHEMATIC:

Assume the temperature of the absorber plates exceeds the ambient air temperature. At the *cover plates*, the relevant processes are:

- $q_{\text{conv},a-i}$ Convection from inside air to inner surface,
- $q_{\text{rad},p-i}$ Net radiation transfer from absorber plates to inner surface,
- $q_{\text{conv},i-o}$ Convection across airspace between covers,
- $q_{\text{rad},i-o}$ Net radiation transfer from inner to outer cover,
- $q_{\text{conv},o-\infty}$ Convection from outer cover to ambient air,
- $q_{\text{rad},o}$ Net radiation transfer from outer cover to surroundings, and
- q_s Incident solar radiation.

Additional processes relevant to the *absorber plates* and *airspace* are:

- $q_{s,t}$ Solar radiation transmitted by cover plates,
- $q_{\text{conv},p-a}$ Convection from absorber plates to inside air, and
- q_{cond} Conduction through insulation.

PROBLEM 1.73(d)

KNOWN: Features of an evacuated tube solar collector.

FIND: Relevant heat transfer processes for one of the tubes.

SCHEMATIC:

The relevant heat transfer processes for one of the evacuated tube solar collectors includes:

- | | |
|-----------------|--|
| q_s | Incident solar radiation including contribution due to reflection off panel (most is transmitted), |
| $q_{conv,o}$ | Convection heat transfer from outer surface to ambient air, |
| $q_{rad,o-sur}$ | Net rate of radiation heat exchange between outer surface of outer tube and the surroundings, including the panel, |
| $q_{s,t}$ | Solar radiation transmitted through outer tube and incident on inner tube (most is absorbed), |
| $q_{rad,i-o}$ | Net rate of radiation heat exchange between outer surface of inner tube and inner surface of outer tube, and |
| $q_{conv,i}$ | Convection heat transfer to working fluid. |

There is also conduction heat transfer through the inner and outer tube walls. If the walls are thin, the temperature drop across the walls will be small.

PROBLEM 2.1

KNOWN: Steady-state, one-dimensional heat conduction through an axisymmetric shape.

FIND: Sketch temperature distribution and explain shape of curve.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Constant properties, (3) No internal heat generation.

ANALYSIS: Performing an energy balance on the object according to Eq. 1.11c, $\dot{E}_{in} - \dot{E}_{out} = 0$, it follows that

$$\dot{E}_{in} - \dot{E}_{out} = q_x$$

and that $q_x \neq q_x(x)$. That is, the heat rate within the object is everywhere constant. From Fourier's law,

$$q_x = -kA_x \frac{dT}{dx},$$

and since q_x and k are both constants, it follows that

$$A_x \frac{dT}{dx} = \text{Constant}.$$

That is, the product of the cross-sectional area normal to the heat rate and temperature gradient remains a constant and independent of distance x . It follows that since A_x increases with x , then dT/dx must decrease with increasing x . Hence, the temperature distribution appears as shown above.

COMMENTS: (1) Be sure to recognize that dT/dx is the slope of the temperature distribution. (2) What would the distribution be when $T_2 > T_1$? (3) How does the heat flux, q_x'' , vary with distance?

PROBLEM 2.2

KNOWN: Hot water pipe covered with thick layer of insulation.

FIND: Sketch temperature distribution and give brief explanation to justify shape.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional (radial) conduction, (3) No internal heat generation, (4) Insulation has uniform properties independent of temperature and position.

ANALYSIS: Fourier's law, Eq. 2.1, for this one-dimensional (cylindrical) radial system has the form

$$q_r = -kA_r \frac{dT}{dr} = -k(2\pi r\ell) \frac{dT}{dr}$$

where $A_r = 2\pi r\ell$ and ℓ is the axial length of the pipe-insulation system. Recognize that for steady-state conditions with no internal heat generation, an energy balance on the system requires

$\dot{E}_{in} = \dot{E}_{out}$ since $\dot{E}_g = \dot{E}_{st} = 0$. Hence

$$q_r = \text{Constant.}$$

That is, q_r is independent of radius (r). Since the thermal conductivity is also constant, it follows that

$$r \left[\frac{dT}{dr} \right] = \text{Constant.}$$

This relation requires that the product of the radial temperature gradient, dT/dr , and the radius, r , remains constant throughout the insulation. For our situation, the temperature distribution must appear as shown in the sketch.

COMMENTS: (1) Note that, while q_r is a constant and independent of r , q_r'' is not a constant. How does $q_r''(r)$ vary with r ? (2) Recognize that the radial temperature gradient, dT/dr , decreases with increasing radius.

PROBLEM 2.3

KNOWN: A spherical shell with prescribed geometry and surface temperatures.

FIND: Sketch temperature distribution and explain shape of the curve.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in radial (spherical coordinates) direction, (3) No internal generation, (4) Constant properties.

ANALYSIS: Fourier's law, Eq. 2.1, for this one-dimensional, radial (spherical coordinate) system has the form

$$q_r = -k A_r \frac{dT}{dr} = -k (4\pi r^2) \frac{dT}{dr}$$

where A_r is the surface area of a sphere. For steady-state conditions, an energy balance on the system yields $\dot{E}_{in} = \dot{E}_{out}$, since $\dot{E}_g = \dot{E}_{st} = 0$. Hence,

$$q_{in} = q_{out} = q_r \neq q_r(r).$$

That is, q_r is a constant, independent of the radial coordinate. Since the thermal conductivity is constant, it follows that

$$r^2 \left[\frac{dT}{dr} \right] = \text{Constant}.$$

This relation requires that the product of the radial temperature gradient, dT/dr , and the radius squared, r^2 , remains constant throughout the shell. Hence, the temperature distribution appears as shown in the sketch.

COMMENTS: Note that, for the above conditions, $q_r \neq q_r(r)$; that is, q_r is everywhere constant.

How does q_r'' vary as a function of radius?

PROBLEM 2.4

KNOWN: Symmetric shape with prescribed variation in cross-sectional area, temperature distribution and heat rate.

FIND: Expression for the thermal conductivity, k .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x -direction, (3) No internal heat generation.

ANALYSIS: Applying the energy balance, Eq. 1.11c, to the system, it follows that, since $\dot{E}_{in} = \dot{E}_{out}$,

$$q_x = \text{Constant} \neq f(x).$$

Using Fourier's law, Eq. 2.1, with appropriate expressions for A_x and T , yields

$$q_x = -k A_x \frac{dT}{dx}$$

$$6000 \text{ W} = -k \cdot (1-x) \text{ m}^2 \cdot \frac{d}{dx} \left[300(1-2x-x^3) \right] \frac{\text{K}}{\text{m}}.$$

Solving for k and recognizing its units are $\text{W/m}\cdot\text{K}$,

$$k = \frac{-6000}{(1-x) \left[300(-2-3x^2) \right]} = \frac{20}{(1-x)(2+3x^2)}.$$

COMMENTS: (1) At $x = 0$, $k = 10 \text{ W/m}\cdot\text{K}$ and $k \rightarrow \infty$ as $x \rightarrow 1$. (2) Recognize that the 1-D assumption is an approximation which becomes more inappropriate as the area change with x , and hence two-dimensional effects, become more pronounced.

PROBLEM 2.5

KNOWN: End-face temperatures and temperature dependence of k for a truncated cone.

FIND: Variation with axial distance along the cone of q_x , q_x'' , k , and dT/dx .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x (negligible temperature gradients in the r direction), (2) Steady-state conditions, (3) Adiabatic sides, (4) No internal heat generation.

ANALYSIS: For the prescribed conditions, it follows from conservation of energy, Eq. 1.11c, that for a differential control volume, $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ or $q_x = q_{x+dx}$. Hence

q_x is independent of x .

Since $A(x)$ increases with increasing x , it follows that $q_x'' = q_x / A(x)$ decreases with increasing x .

Since T decreases with increasing x , k increases with increasing x . Hence, from Fourier's law, Eq. 2.2,

$$q_x'' = -k \frac{dT}{dx},$$

it follows that $|dT/dx|$ decreases with increasing x .

COMMENT: How is the analysis changed if a has a negative value?

PROBLEM 2.6

KNOWN: Temperature dependence of the thermal conductivity, $k(T)$, for heat transfer through a plane wall.

FIND: Effect of $k(T)$ on temperature distribution, $T(x)$.

ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) No internal heat generation.

ANALYSIS: From Fourier's law and the form of $k(T)$,

$$q_x'' = -k \frac{dT}{dx} = -(k_o + aT) \frac{dT}{dx}. \quad (1)$$

The shape of the temperature distribution may be inferred from knowledge of $d^2T/dx^2 = d(dT/dx)/dx$. Since q_x'' is independent of x for the prescribed conditions,

$$\begin{aligned} \frac{dq_x''}{dx} &= -\frac{d}{dx} \left[(k_o + aT) \frac{dT}{dx} \right] = 0 \\ -(k_o + aT) \frac{d^2T}{dx^2} - a \left[\frac{dT}{dx} \right]^2 &= 0. \end{aligned}$$

Hence,

$$\frac{d^2T}{dx^2} = \frac{-a}{k_o + aT} \left[\frac{dT}{dx} \right]^2 \quad \text{where} \quad \begin{cases} k_o + aT = k > 0 \\ \left[\frac{dT}{dx} \right]^2 > 0 \end{cases}$$

from which it follows that for

$$a > 0: \quad d^2T/dx^2 < 0$$

$$a = 0: \quad d^2T/dx^2 = 0$$

$$a < 0: \quad d^2T/dx^2 > 0.$$

COMMENTS: The shape of the distribution could also be inferred from Eq. (1). Since T decreases with increasing x ,

$$a > 0: \quad k \text{ decreases with increasing } x \Rightarrow |dT/dx| \text{ increases with increasing } x$$

$$a = 0: \quad k = k_o \Rightarrow dT/dx \text{ is constant}$$

$$a < 0: \quad k \text{ increases with increasing } x \Rightarrow |dT/dx| \text{ decreases with increasing } x.$$

PROBLEM 2.7

KNOWN: Irradiation and absorptivity of aluminum, glass and aerogel.

FIND: Ability of the protective barrier to withstand the irradiation in terms of the temperature gradients that develop in response to the irradiation.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Constant properties, (c) Negligible emission and convection from the exposed surface.

PROPERTIES: Table A.1, pure aluminum (300 K): $k_{al} = 238 \text{ W/m}\cdot\text{K}$. Table A.3, glass (300 K): $k_{gl} = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: From Eqs. 1.6 and 2.30

$$-k \left. \frac{\partial T}{\partial x} \right|_{x=0} = q_s'' = G_{\text{abs}} = \alpha G$$

or

$$\left. \frac{\partial T}{\partial x} \right|_{x=0} = -\frac{\alpha G}{k}$$

The temperature gradients at $x = 0$ for the three materials are:

<

<u>Material</u>	$\left. \frac{\partial T}{\partial x} \right _{x=0} \text{ (K/m)}$
aluminum	8.4×10^3
glass	6.4×10^6
aerogel	1.6×10^9

COMMENT: It is unlikely that the aerogel barrier can sustain the thermal stresses associated with the large temperature gradient. Low thermal conductivity solids are prone to large temperature gradients, and are often brittle.

PROBLEM 2.8

KNOWN: One-dimensional system with prescribed thermal conductivity and thickness.

FIND: Unknowns for various temperature conditions and sketch distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) No internal heat generation, (4) Constant properties.

ANALYSIS: The rate equation and temperature gradient for this system are

$$q''_x = -k \frac{dT}{dx} \quad \text{and} \quad \frac{dT}{dx} = \frac{T_2 - T_1}{L}. \quad (1,2)$$

Using Eqs. (1) and (2), the unknown quantities for each case can be determined.

(a) $\frac{dT}{dx} = \frac{(-20 - 50) \text{ K}}{0.25 \text{ m}} = -280 \text{ K/m}$

$$q''_x = -50 \frac{\text{W}}{\text{m} \cdot \text{K}} \times \left[-280 \frac{\text{K}}{\text{m}} \right] = 14.0 \text{ kW/m}^2.$$

<

(b) $\frac{dT}{dx} = \frac{(-10 - (-30)) \text{ K}}{0.25 \text{ m}} = 80 \text{ K/m}$

$$q''_x = -50 \frac{\text{W}}{\text{m} \cdot \text{K}} \times \left[80 \frac{\text{K}}{\text{m}} \right] = -4.0 \text{ kW/m}^2.$$

<

(c) $q''_x = -50 \frac{\text{W}}{\text{m} \cdot \text{K}} \times \left[160 \frac{\text{K}}{\text{m}} \right] = -8.0 \text{ kW/m}^2$

$$T_2 = L \cdot \frac{dT}{dx} + T_1 = 0.25 \text{ m} \times \left[160 \frac{\text{K}}{\text{m}} \right] + 70^\circ \text{C}.$$

$$T_2 = 110^\circ \text{C}.$$

<

(d) $q''_x = -50 \frac{\text{W}}{\text{m} \cdot \text{K}} \times \left[-80 \frac{\text{K}}{\text{m}} \right] = 4.0 \text{ kW/m}^2$

$$T_1 = T_2 - L \cdot \frac{dT}{dx} = 40^\circ \text{C} - 0.25 \text{ m} \times \left[-80 \frac{\text{K}}{\text{m}} \right]$$

$$T_1 = 60^\circ \text{C}.$$

<

(e) $q''_x = -50 \frac{\text{W}}{\text{m} \cdot \text{K}} \times \left[200 \frac{\text{K}}{\text{m}} \right] = -10.0 \text{ kW/m}^2$

$$T_1 = T_2 - L \cdot \frac{dT}{dx} = 30^\circ \text{C} - 0.25 \text{ m} \times \left[200 \frac{\text{K}}{\text{m}} \right] = -20^\circ \text{C}.$$

<

PROBLEM 2.9

KNOWN: Plane wall with prescribed thermal conductivity, thickness, and surface temperatures.

FIND: Heat flux, q''_x , and temperature gradient, dT/dx , for the three different coordinate systems shown.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat flow, (2) Steady-state conditions, (3) No internal generation, (4) Constant properties.

ANALYSIS: The rate equation for conduction heat transfer is

$$q''_x = -k \frac{dT}{dx}, \quad (1)$$

where the temperature gradient is constant throughout the wall and of the form

$$\frac{dT}{dx} = \frac{T(L) - T(0)}{L}. \quad (2)$$

Substituting numerical values, find the temperature gradients,

$$(a) \quad \frac{dT}{dx} = \frac{T_2 - T_1}{L} = \frac{(600 - 400)\text{K}}{0.100\text{m}} = 2000 \text{ K/m} <$$

$$(b) \quad \frac{dT}{dx} = \frac{T_1 - T_2}{L} = \frac{(400 - 600)\text{K}}{0.100\text{m}} = -2000 \text{ K/m} <$$

$$(c) \quad \frac{dT}{dx} = \frac{T_2 - T_1}{L} = \frac{(600 - 400)\text{K}}{0.100\text{m}} = 2000 \text{ K/m} <$$

The heat rates, using Eq. (1) with $k = 100 \text{ W/m}\cdot\text{K}$, are

$$(a) \quad q''_x = -100 \frac{\text{W}}{\text{m}\cdot\text{K}} \times 2000 \text{ K/m} = -200 \text{ kW/m}^2 <$$

$$(b) \quad q''_x = -100 \frac{\text{W}}{\text{m}\cdot\text{K}} (-2000 \text{ K/m}) = +200 \text{ kW/m}^2 <$$

$$(c) \quad q''_x = -100 \frac{\text{W}}{\text{m}\cdot\text{K}} \times 2000 \text{ K/m} = -200 \text{ kW/m}^2 <$$

PROBLEM 2.10

KNOWN: Temperature distribution in solid cylinder and convection coefficient at cylinder surface.

FIND: Expressions for heat rate at cylinder surface and fluid temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: The heat rate from Fourier's law for the radial (cylindrical) system has the form

$$q_r = -kA_r \frac{dT}{dr}.$$

Substituting for the temperature distribution, $T(r) = a + br^2$,

$$q_r = -k(2\pi rL) 2br = -4\pi kbLr^2.$$

At the outer surface ($r = r_o$), the conduction heat rate is

$$q_{r=r_o} = -4\pi kbLr_o^2.$$

<

From a surface energy balance at $r = r_o$,

$$q_{r=r_o} = q_{\text{conv}} = h(2\pi r_o L) [T(r_o) - T_\infty],$$

Substituting for $q_{r=r_o}$ and solving for T_∞ ,

$$T_\infty = T(r_o) + \frac{2kbr_o}{h}$$

$$T_\infty = a + br_o^2 + \frac{2kbr_o}{h}$$

$$T_\infty = a + br_o \left[r_o + \frac{2k}{h} \right].$$

<

PROBLEM 2.11

KNOWN: Two-dimensional body with specified thermal conductivity and two isothermal surfaces of prescribed temperatures; one surface, A, has a prescribed temperature gradient.

FIND: Temperature gradients, $\partial T/\partial x$ and $\partial T/\partial y$, at the surface B.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) No heat generation, (4) Constant properties.

ANALYSIS: At the surface A, the temperature gradient in the x-direction must be zero. That is, $(\partial T/\partial x)_A = 0$. This follows from the requirement that the heat flux vector must be normal to an isothermal surface. The heat rate at the surface A is given by Fourier's law written as

$$q'_{y,A} = -k \cdot w_A \left. \frac{\partial T}{\partial y} \right|_A = -10 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 2 \text{ m} \times 30 \frac{\text{K}}{\text{m}} = -600 \text{ W/m}.$$

On the surface B, it follows that

$$(\partial T/\partial y)_B = 0$$

in order to satisfy the requirement that the heat flux vector be normal to the isothermal surface B. Using the conservation of energy requirement, Eq. 1.11c, on the body, find

$$q'_{y,A} - q'_{x,B} = 0 \quad \text{or} \quad q'_{x,B} = q'_{y,A}.$$

Note that,

$$q'_{x,B} = -k \cdot w_B \left. \frac{\partial T}{\partial x} \right|_B$$

and hence

$$(\partial T/\partial x)_B = \frac{-q'_{y,A}}{k \cdot w_B} = \frac{-(-600 \text{ W/m})}{10 \text{ W/m} \cdot \text{K} \times 1 \text{ m}} = 60 \text{ K/m}.$$

COMMENTS: Note that, in using the conservation requirement, $q'_{\text{in}} = +q'_{y,A}$ and $q'_{\text{out}} = +q'_{x,B}$.

PROBLEM 2.12

KNOWN: Length and thermal conductivity of a shaft. Temperature distribution along shaft.

FIND: Temperature and heat rates at ends of shaft.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x , (3) Constant properties.

ANALYSIS: Temperatures at the top and bottom of the shaft are, respectively,

$$T(0) = 100^\circ\text{C}$$

$$T(L) = -40^\circ\text{C}.$$

<

Applying Fourier's law, Eq. 2.1,

$$q_x = -kA \frac{dT}{dx} = -25\text{ W/m}\cdot\text{K} \left(0.005\text{ m}^2 \right) (-150 + 20x)^\circ\text{C/m}$$

$$q_x = 0.125(150 - 20x)\text{ W}.$$

Hence,

$$q_x(0) = 18.75\text{ W}$$

$$q_x(L) = 16.25\text{ W}.$$

<

The difference in heat rates, $q_x(0) > q_x(L)$, is due to heat losses q_ℓ from the side of the shaft.

COMMENTS: Heat loss from the side requires the existence of temperature gradients over the shaft cross-section. Hence, specification of T as a function of only x is an approximation.

PROBLEM 2.13

KNOWN: A rod of constant thermal conductivity k and variable cross-sectional area $A_x(x) = A_o e^{ax}$ where A_o and a are constants.

FIND: (a) Expression for the conduction heat rate, $q_x(x)$; use this expression to determine the temperature distribution, $T(x)$; and sketch of the temperature distribution, (b) Considering the presence of volumetric heat generation rate, $\dot{q} = \dot{q}_o \exp(-ax)$, obtain an expression for $q_x(x)$ when the left face, $x = 0$, is well insulated.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the rod, (2) Constant properties, (3) Steady-state conditions.

ANALYSIS: Perform an energy balance on the control volume, $A(x) \cdot dx$,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0$$

$$q_x - q_{x+dx} + \dot{q} \cdot A(x) \cdot dx = 0$$

The conduction heat rate terms can be expressed as a Taylor series and substituting expressions for \dot{q} and $A(x)$,

$$-\frac{d}{dx}(q_x) + \dot{q}_o \exp(-ax) \cdot A_o \exp(ax) = 0 \quad (1)$$

$$q_x = -k \cdot A(x) \frac{dT}{dx} \quad (2)$$

(a) With no internal generation, $\dot{q}_o = 0$, and from Eq. (1) find

$$-\frac{d}{dx}(q_x) = 0 \quad <$$

indicating that the heat rate is constant with x . By combining Eqs. (1) and (2)

$$-\frac{d}{dx} \left(-k \cdot A(x) \frac{dT}{dx} \right) = 0 \quad \text{or} \quad A(x) \cdot \frac{dT}{dx} = C_1 \quad (3) \quad <$$

Continued...

PROBLEM 2.13 (Cont.)

That is, the product of the cross-sectional area and the temperature gradient is a constant, independent of x . Hence, with $T(0) > T(L)$, the temperature distribution is exponential, and as shown in the sketch above. Separating variables and integrating Eq. (3), the general form for the temperature distribution can be determined,

$$A_o \exp(ax) \cdot \frac{dT}{dx} = C_1$$

$$dT = C_1 A_o^{-1} \exp(-ax) dx$$

$$T(x) = -C_1 A_o a \exp(-ax) + C_2$$

<

We could use the two temperature boundary conditions, $T_o = T(0)$ and $T_L = T(L)$, to evaluate C_1 and C_2 and, hence, obtain the temperature distribution in terms of T_o and T_L .

(b) With the internal generation, from Eq. (1),

$$-\frac{d}{dx}(q_x) + \dot{q}_o A_o = 0$$

or

$$q_x = \dot{q}_o A_o x$$

<

That is, the heat rate increases linearly with x .

COMMENTS: In part (b), you could determine the temperature distribution using Fourier's law and knowledge of the heat rate dependence upon the x -coordinate. Give it a try!

PROBLEM 2.14

KNOWN: Dimensions of and temperature difference across an aircraft window. Window materials and cost of energy.

FIND: Heat loss through one window and cost of heating for 180 windows on 8-hour trip.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in the x-direction, (3) Constant properties.

PROPERTIES: Table A.3, soda lime glass (300 K): $k_{gl} = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: From Eq. 2.1,

$$q_x = -kA \frac{dT}{dx} = k a b \frac{(T_1 - T_2)}{L}$$

For glass,

$$q_{x,g} = 1.4 \frac{\text{W}}{\text{m}\cdot\text{K}} \times 0.3 \text{ m} \times 0.3 \text{ m} \times \left[\frac{80^\circ\text{C}}{0.01\text{m}} \right] = 1010 \text{ W} \quad <$$

The cost associated with heat loss through N windows at a rate of $R = \$1/\text{kW}\cdot\text{h}$ over a $t = 8 \text{ h}$ flight time is

$$C_g = Nq_{x,g}Rt = 130 \times 1010 \text{ W} \times 1 \frac{\$}{\text{kW}\cdot\text{h}} \times 8 \text{ h} \times \frac{1\text{kW}}{1000\text{W}} = \$1050 \quad <$$

Repeating the calculation for the polycarbonate yields

$$q_{x,p} = 151 \text{ W}, C_p = \$157 \quad <$$

while for aerogel,

$$q_{x,a} = 10.1 \text{ W}, C_a = \$10 \quad <$$

COMMENT: Polycarbonate provides significant savings relative to glass. It is also lighter ($\rho_p = 1200 \text{ kg/m}^3$) relative to glass ($\rho_g = 2500 \text{ kg/m}^3$). The aerogel offers the best thermal performance and is very light ($\rho_a = 2 \text{ kg/m}^3$) but would be relatively expensive.

PROBLEM 2.15

KNOWN: Dimensions of and temperature difference applied across thin gold film.

FIND: (a) Energy conducted along the film, (b) Plot the thermal conductivity along and across the thin dimension of the film, for film thicknesses $30 \leq L \leq 140$ nm.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x- and y-directions, (2) Steady-state conditions, (3) Constant properties, (4) Thermal conductivity not affected by nanoscale effects associated with 250 nm dimension.

PROPERTIES: Table A.1, gold (bulk, 300 K): $k = 317$ W/m·K.

ANALYSIS:

a) From Eq. 2.1,

$$q_x = -kA \frac{dT}{dx} = k_x Lb \left[\frac{T_1 - T_2}{a} \right] \quad (1)$$

From Eq. 2.9a,

$$k_x = k \left[1 - 2\lambda_{\text{mfp}} / (3\pi L) \right] \quad (2)$$

Combining Eqs. (1) and (2), and using the value of $\lambda_{\text{mfp}} = 31$ nm from Table 2.1 yields

$$\begin{aligned} q_x &= k \left[1 - 2\lambda_{\text{mfp}} / (3\pi L) \right] Lb \left[\frac{T_1 - T_2}{a} \right] \\ &= 317 \frac{\text{W}}{\text{m} \cdot \text{K}} \times \left[1 - \frac{2 \times 31 \times 10^{-9} \text{ m}}{3 \times \pi \times 60 \times 10^{-9} \text{ m}} \right] \times 60 \times 10^{-9} \text{ m} \times 250 \times 10^{-9} \text{ m} \times \frac{20^\circ\text{C}}{1 \times 10^{-6} \text{ m}} \\ &= 85 \times 10^{-6} \text{ W} = 85 \mu\text{W} \end{aligned} \quad <$$

(b) The spanwise thermal conductivity may be found from Eq. 2.9b,

$$k_y = k \left[1 - \lambda_{\text{mfp}} / (3L) \right] \quad (3)$$

Continued...

PROBLEM 2.15 (Cont.)

The plot is shown below.

COMMENT: Nanoscale effects become less significant as the thickness of the film is increased.

PROBLEM 2.16

KNOWN: Different thicknesses of three materials: rock, 18 ft; wood, 15 in; and fiberglass insulation, 6 in.

FIND: The insulating quality of the materials as measured by the R-value.

PROPERTIES: Table A-3 (300K):

Material	Thermal conductivity, W/m·K
Limestone	2.15
Softwood	0.12
Blanket (glass, fiber 10 kg/m ³)	0.048

ANALYSIS: The R-value, a quantity commonly used in the construction industry and building technology, is defined as

$$R \equiv \frac{L(\text{in})}{k \left(\text{Btu} \cdot \text{in} / \text{h} \cdot \text{ft}^2 \cdot ^\circ \text{F} \right)}.$$

The R-value can be interpreted as the thermal resistance of a 1 ft² cross section of the material. Using the conversion factor for thermal conductivity between the SI and English systems, the R-values are:

Rock, Limestone, 18 ft:

$$R = \frac{18 \text{ ft} \times 12 \frac{\text{in}}{\text{ft}}}{2.15 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 0.5778 \frac{\text{Btu} \cdot \text{h} \cdot \text{ft}^2 \cdot ^\circ \text{F}}{\text{W} \cdot \text{m} \cdot \text{K}} \times 12 \frac{\text{in}}{\text{ft}}} = 14.5 \left(\text{Btu} \cdot \text{h} \cdot \text{ft}^2 \cdot ^\circ \text{F} \right)^{-1} <$$

Wood, Softwood, 15 in:

$$R = \frac{15 \text{ in}}{0.12 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 0.5778 \frac{\text{Btu} \cdot \text{h} \cdot \text{ft}^2 \cdot ^\circ \text{F}}{\text{W} \cdot \text{m} \cdot \text{K}} \times 12 \frac{\text{in}}{\text{ft}}} = 18 \left(\text{Btu} \cdot \text{h} \cdot \text{ft}^2 \cdot ^\circ \text{F} \right)^{-1} <$$

Insulation, Blanket, 6 in:

$$R = \frac{6 \text{ in}}{0.048 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 0.5778 \frac{\text{Btu} \cdot \text{h} \cdot \text{ft}^2 \cdot ^\circ \text{F}}{\text{W} \cdot \text{m} \cdot \text{K}} \times 12 \frac{\text{in}}{\text{ft}}} = 18 \left(\text{Btu} \cdot \text{h} \cdot \text{ft}^2 \cdot ^\circ \text{F} \right)^{-1} <$$

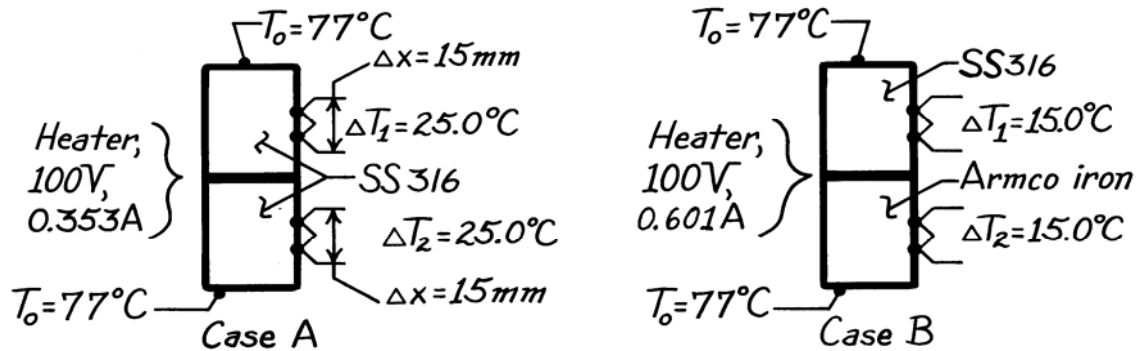

COMMENTS: The R-value of 19 given in the advertisement is reasonable.

PROBLEM 2.17

KNOWN: Electrical heater sandwiched between two identical cylindrical (30 mm dia. \times 60 mm length) samples whose opposite ends contact plates maintained at T_o .

FIND: (a) Thermal conductivity of SS316 samples for the prescribed conditions (A) and their average temperature, (b) Thermal conductivity of Armco iron sample for the prescribed conditions (B), (c) Comment on advantages of experimental arrangement, lateral heat losses, and conditions for which $\Delta T_1 \neq \Delta T_2$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer in samples, (2) Steady-state conditions, (3) Negligible contact resistance between materials.

PROPERTIES: Table A.2, Stainless steel 316 ($\bar{T}=400$ K): $k_{ss} = 15.2$ W/m \cdot K; Armco iron ($\bar{T}=380$ K): $k_{iron} = 67.2$ W/m \cdot K.

ANALYSIS: (a) For Case A recognize that half the heater power will pass through each of the samples which are presumed identical. Apply Fourier's law to a sample

$$q = kA_c \frac{\Delta T}{\Delta x}$$

$$k = \frac{q \Delta x}{A_c \Delta T} = \frac{0.5(100\text{V} \times 0.353\text{A}) \times 0.015\text{ m}}{\pi(0.030\text{ m})^2 / 4 \times 25.0^\circ\text{C}} = 15.0\text{ W/m} \cdot \text{K}. \quad <$$

The total temperature drop across the length of the sample is $\Delta T_1(L/\Delta x) = 25^\circ\text{C} (60\text{ mm}/15\text{ mm}) = 100^\circ\text{C}$. Hence, the heater temperature is $T_h = 177^\circ\text{C}$. Thus the average temperature of the sample is

$$\bar{T} = (T_o + T_h) / 2 = 127^\circ\text{C} = 400\text{ K}. \quad <$$

We compare the calculated value of k with the tabulated value (see above) at 400 K and note the good agreement.

(b) For Case B, we assume that the thermal conductivity of the SS316 sample is the same as that found in Part (a). The heat rate through the Armco iron sample is

Continued

PROBLEM 2.17 (CONT.)

$$q_{\text{iron}} = q_{\text{heater}} - q_{\text{ss}} = 100\text{V} \times 0.601\text{A} - 15.0\text{ W/m} \cdot \text{K} \times \frac{\pi(0.030\text{ m})^2}{4} \times \frac{15.0^\circ\text{C}}{0.015\text{ m}}$$
$$q_{\text{iron}} = (60.1 - 10.6)\text{ W} = 49.5\text{ W}$$

where

$$q_{\text{ss}} = k_{\text{ss}} A_c \Delta T_2 / \Delta x_2.$$

Applying Fourier's law to the iron sample,

$$k_{\text{iron}} = \frac{q_{\text{iron}} \Delta x_2}{A_c \Delta T_2} = \frac{49.5\text{ W} \times 0.015\text{ m}}{\pi(0.030\text{ m})^2 / 4 \times 15.0^\circ\text{C}} = 70.0\text{ W/m} \cdot \text{K}. \quad <$$

The total drop across the iron sample is $15^\circ\text{C}(60/15) = 60^\circ\text{C}$; the heater temperature is $(77 + 60)^\circ\text{C} = 137^\circ\text{C}$. Hence the average temperature of the iron sample is

$$\bar{T} = (137 + 77)^\circ\text{C} / 2 = 107^\circ\text{C} = 380\text{ K}. \quad <$$

We compare the computed value of k with the tabulated value (see above) at 380 K and note the good agreement.

(c) The principal advantage of having two identical samples is the assurance that all the electrical power dissipated in the heater will appear as equivalent heat flows through the samples. With only one sample, heat can flow from the backside of the heater even though insulated.

Heat leakage out the lateral surfaces of the cylindrically shaped samples will become significant when the sample thermal conductivity is comparable to that of the insulating material. Hence, the method is suitable for metallics, but must be used with caution on nonmetallic materials.

For any combination of materials in the upper and lower position, we expect $\Delta T_1 = \Delta T_2$. However, if the insulation were improperly applied along the lateral surfaces, it is possible that heat leakage will occur, causing $\Delta T_1 \neq \Delta T_2$.

PROBLEM 2.18

KNOWN: Geometry and steady-state conditions used to measure the thermal conductivity of an aerogel sheet.

FIND: (a) Reason the apparatus of Problem 2.17 cannot be used, (b) Thermal conductivity of the aerogel, (c) Temperature difference across the aluminum sheets, and (d) Outlet temperature of the coolant.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer.

PROPERTIES: Table A.1, pure aluminum [$T = (T_1 + T_{c,i})/2 = 40^\circ\text{C} = 313\text{ K}$]: $k_{\text{al}} = 239\text{ W/m}\cdot\text{K}$. Table A.6, liquid water ($25^\circ\text{C} = 298\text{ K}$): $c_p = 4180\text{ J/kg}\cdot\text{K}$.

ANALYSIS:

(a) The apparatus of Problem 2.17 cannot be used because it operates under the assumption that the heat transfer is one-dimensional in the axial direction. Since the aerogel is expected to have an extremely small thermal conductivity, the insulation used in Problem 2.17 will likely have a higher thermal conductivity than aerogel. Radial heat losses would be significant, invalidating any measured results.

(b) The electrical power is

$$\dot{E}_g = V(I) = 10\text{ V} \times 0.125\text{ A} = 1.25\text{ W}$$

Continued...

PROBLEM 2.18 (Cont.)

The conduction heat rate through each aerogel plate is

$$q = \frac{\dot{E}_g}{2} = -k_a A \frac{dT}{dx} = -k_a \left(\frac{\pi D^2}{4} \right) \left(\frac{T_c - T_l}{t} \right)$$

or

$$k_a = \frac{2\dot{E}_g t}{\pi D^2 (T_l - T_c)} = \frac{2 \times 1.25 \text{ W} \times 0.005 \text{ m}}{\pi \times (0.15 \text{ m})^2 \times (55 - 25)^\circ\text{C}} = 5.9 \times 10^{-3} \frac{\text{W}}{\text{m} \cdot \text{K}} <$$

(c) The conduction heat flux through each aluminum plate is the same as through the aerogel. Hence,

$$-k_a \frac{(T_c - T_l)}{t} = -k_{al} \frac{\Delta T_{al}}{t}$$

$$\text{or } \Delta T_{al} = \frac{k_a}{k_{al}} (T_l - T_c) = \frac{5.9 \times 10^{-3} \text{ W/m} \cdot \text{K}}{239 \text{ W/m} \cdot \text{K}} \times 30^\circ\text{C} = 0.74 \times 10^{-3}^\circ\text{C} <$$

The temperature difference across the aluminum plate is negligible. Therefore it is not important to know the location where the thermocouples are attached.

(d) An energy balance on the water yields

$$\dot{E}_g = \dot{m} c_p (T_{c,o} - T_{c,i})$$

or

$$\begin{aligned} T_{c,o} &= T_{c,i} + \frac{\dot{E}_g}{\dot{m} c_p} \\ &= 25^\circ\text{C} + \frac{1.25 \text{ W}}{1 \text{ kg/min} \times \frac{1}{60} \text{ min/s} \times 4180 \text{ J/kg} \cdot \text{K}} = 25.02^\circ\text{C} < \end{aligned}$$

COMMENTS: (1) For all practical purposes the aluminum plates may be considered to be isothermal. (2) The coolant may be considered to be isothermal.

PROBLEM 2.19

KNOWN: Identical samples of prescribed diameter, length and density initially at a uniform temperature T_i , sandwich an electric heater which provides a uniform heat flux q''_0 for a period of time Δt_0 . Conditions shortly after energizing and a long time after de-energizing heater are prescribed.

FIND: Specific heat and thermal conductivity of the test sample material. From these properties, identify type of material using Table A.1 or A.2.

SCHEMATIC:

ASSUMPTIONS: (1) One dimensional heat transfer in samples, (2) Constant properties, (3) Negligible heat loss through insulation, (4) Negligible heater mass.

ANALYSIS: Consider a control volume about the samples and heater, and apply conservation of energy over the time interval from $t = 0$ to ∞

$$E_{in} - E_{out} = \Delta E = E_f - E_i$$

$$P\Delta t_0 - 0 = Mc_p [T(\infty) - T_i]$$

where energy inflow is prescribed by the power condition and the final temperature T_f is known.

Solving for c_p ,

$$c_p = \frac{P\Delta t_0}{M[T(\infty) - T_i]} = \frac{15 \text{ W} \times 120 \text{ s}}{2 \times 3965 \text{ kg/m}^3 \left(\pi \times 0.060^2 / 4 \right) \text{ m}^2 \times 0.010 \text{ m} [33.50 - 23.00]^\circ \text{C}}$$

$$c_p = 765 \text{ J / kg} \cdot \text{K}$$

<

where $M = \rho V = 2\rho(\pi D^2/4)L$ is the mass of both samples. The transient thermal response of the heater is given by

Continued

PROBLEM 2.19 (Cont.)

$$T_o(t) - T_i = 2q_o'' \left[\frac{t}{\pi \rho c_p k} \right]^{1/2}$$

$$k = \frac{t}{\pi \rho c_p} \left[\frac{2q_o''}{T_o(t) - T_i} \right]^2$$

$$k = \frac{30 \text{ s}}{\pi \times 3965 \text{ kg/m}^3 \times 765 \text{ J/kg} \cdot \text{K}} \left[\frac{2 \times 2653 \text{ W/m}^2}{(24.57 - 23.00)^\circ \text{C}} \right]^2 = 36.0 \text{ W/m} \cdot \text{K} \quad <$$

where

$$q_o'' = \frac{P}{2A_s} = \frac{P}{2(\pi D^2/4)} = \frac{15 \text{ W}}{2(\pi \times 0.060^2/4) \text{ m}^2} = 2653 \text{ W/m}^2.$$

With the following properties now known,

$$\rho = 3965 \text{ kg/m}^3 \qquad c_p = 765 \text{ J/kg} \cdot \text{K} \qquad k = 36 \text{ W/m} \cdot \text{K}$$

entries in Table A.1 are scanned to determine whether these values are typical of a metallic material. Consider the following,

- metallics with low ρ generally have higher thermal conductivities,
- specific heats of both types of materials are of similar magnitude,
- the low k value of the sample is typical of poor metallic conductors which generally have much higher specific heats,
- more than likely, the material is nonmetallic.

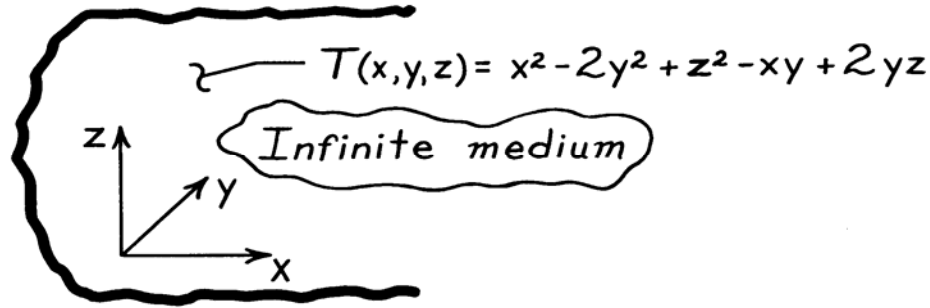

From Table A.2, the second entry, polycrystalline aluminum oxide, has properties at 300 K corresponding to those found for the samples. <

PROBLEM 2.20

KNOWN: Temperature distribution, $T(x,y,z)$, within an infinite, homogeneous body at a given instant of time.

FIND: Regions where the temperature changes with time.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties of infinite medium and (2) No internal heat generation.

ANALYSIS: The temperature distribution throughout the medium, at any instant of time, must satisfy the heat equation. For the three-dimensional cartesian coordinate system, with constant properties and no internal heat generation, the heat equation, Eq. 2.19, has the form

$$\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}. \quad (1)$$

If $T(x,y,z)$ satisfies this relation, conservation of energy is satisfied at every point in the medium.

Substituting $T(x,y,z)$ into the Eq. (1), first find the gradients, $\partial T/\partial x$, $\partial T/\partial y$, and $\partial T/\partial z$.

$$\frac{\partial}{\partial x}(2x-y) + \frac{\partial}{\partial y}(-4y-x+2z) + \frac{\partial}{\partial z}(2z+2y) = \frac{1}{\alpha} \frac{\partial T}{\partial t}.$$

Performing the differentiations,

$$2 - 4 + 2 = \frac{1}{\alpha} \frac{\partial T}{\partial t}.$$

Hence,

$$\frac{\partial T}{\partial t} = 0$$

which implies that, at the prescribed instant, the temperature is everywhere independent of time. <

COMMENTS: Since we do not know the initial and boundary conditions, we cannot determine the temperature distribution, $T(x,y,z)$, at any future time. We can only determine that, for this special instant of time, the temperature will not change.

PROBLEM 2.21

KNOWN: Diameter D , thickness L and initial temperature T_i of pan. Heat rate from stove to bottom of pan. Convection coefficient h and variation of water temperature $T_\infty(t)$ during Stage 1. Temperature T_L of pan surface in contact with water during Stage 2.

FIND: Form of heat equation and boundary conditions associated with the two stages.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in pan bottom, (2) Heat transfer from stove is uniformly distributed over surface of pan in contact with the stove, (3) Constant properties.

ANALYSIS:

Stage 1

Heat Equation:
$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

Boundary Conditions:
$$-k \left. \frac{\partial T}{\partial x} \right|_{x=0} = q_o'' = \frac{q_o}{(\pi D^2 / 4)}$$

$$-k \left. \frac{\partial T}{\partial x} \right|_{x=L} = h [T(L, t) - T_\infty(t)]$$

Initial Condition:
$$T(x, 0) = T_i$$

Stage 2

Heat Equation:
$$\frac{d^2 T}{dx^2} = 0$$

Boundary Conditions:
$$-k \left. \frac{dT}{dx} \right|_{x=0} = q_o''$$

$$T(L) = T_L$$

COMMENTS: Stage 1 is a transient process for which $T_\infty(t)$ must be determined separately. As a first approximation, it could be estimated by neglecting changes in thermal energy storage by the pan bottom and assuming that all of the heat transferred from the stove acted to increase thermal energy storage within the water. Hence, with $q \approx Mc_p dT_\infty/dt$, where M and c_p are the mass and specific heat of the water in the pan, $T_\infty(t) \approx (q/Mc_p) t$.

PROBLEM 2.22

KNOWN: Steady-state temperature distribution in a cylindrical rod having uniform heat generation of $\dot{q}_1 = 5 \times 10^7 \text{ W/m}^3$.

FIND: (a) Steady-state centerline and surface heat transfer rates per unit length, q'_r . (b) Initial time rate of change of the centerline and surface temperatures in response to a change in the generation rate from \dot{q}_1 to $\dot{q}_2 = 10^8 \text{ W/m}^3$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the r direction, (2) Uniform generation, and (3) Steady-state for $\dot{q}_1 = 5 \times 10^7 \text{ W/m}^3$.

ANALYSIS: (a) From the rate equations for cylindrical coordinates,

$$q''_r = -k \frac{\partial T}{\partial r} \quad q = -kA_r \frac{\partial T}{\partial r}.$$

Hence,

$$q_r = -k(2\pi rL) \frac{\partial T}{\partial r}$$

or

$$q'_r = -2\pi k r \frac{\partial T}{\partial r} \tag{1}$$

where $\partial T / \partial r$ may be evaluated from the prescribed temperature distribution, $T(r)$.

At $r = 0$, the gradient is $(\partial T / \partial r) = 0$. Hence, from Equation (1) the heat rate is

$$q'_r(0) = 0. \quad <$$

At $r = r_o$, the temperature gradient is

$$\begin{aligned} \left. \frac{\partial T}{\partial r} \right|_{r=r_o} &= -2 \left[4.167 \times 10^5 \frac{\text{K}}{\text{m}^2} \right] (r_o) = -2 (4.167 \times 10^5) (0.025 \text{ m}) \\ \left. \frac{\partial T}{\partial r} \right|_{r=r_o} &= -0.208 \times 10^5 \text{ K/m}. \end{aligned}$$

Continued

PROBLEM 2.22 (Cont.)

Hence, the heat rate at the outer surface ($r = r_o$) per unit length is

$$q'_r(r_o) = -2\pi[30 \text{ W/m} \cdot \text{K}](0.025\text{m})[-0.208 \times 10^5 \text{ K/m}]$$

$$q'_r(r_o) = 0.980 \times 10^5 \text{ W/m.}$$

<

(b) Transient (time-dependent) conditions will exist when the generation is changed, and for the prescribed assumptions, the temperature is determined by the following form of the heat equation, Equation 2.24

$$\frac{1}{r} \frac{\partial}{\partial r} \left[kr \frac{\partial T}{\partial r} \right] + \dot{q}_2 = \rho c_p \frac{\partial T}{\partial t}$$

Hence

$$\frac{\partial T}{\partial t} = \frac{1}{\rho c_p} \left[\frac{1}{r} \frac{\partial}{\partial r} \left[kr \frac{\partial T}{\partial r} \right] + \dot{q}_2 \right].$$

However, initially (at $t = 0$), the temperature distribution is given by the prescribed form, $T(r) = 800 - 4.167 \times 10^5 r^2$, and

$$\begin{aligned} \frac{1}{r} \frac{\partial}{\partial r} \left[kr \frac{\partial T}{\partial r} \right] &= \frac{k}{r} \frac{\partial}{\partial r} \left[r \left(-8.334 \times 10^5 \cdot r \right) \right] \\ &= \frac{k}{r} \left(-16.668 \times 10^5 \cdot r \right) \\ &= 30 \text{ W/m} \cdot \text{K} \left[-16.668 \times 10^5 \text{ K/m}^2 \right] \\ &= -5 \times 10^7 \text{ W/m}^3 \quad (\text{the original } \dot{q} = \dot{q}_1). \end{aligned}$$

Hence, everywhere in the wall,

$$\frac{\partial T}{\partial t} = \frac{1}{1100 \text{ kg/m}^3 \times 800 \text{ J/kg} \cdot \text{K}} \left[-5 \times 10^7 + 10^8 \right] \text{ W/m}^3$$

or

$$\frac{\partial T}{\partial t} = 56.82 \text{ K/s.}$$

<

COMMENTS: (1) The value of $(\partial T / \partial t)$ will decrease with increasing time, until a new steady-state condition is reached and once again $(\partial T / \partial t) = 0$.

(2) By applying the energy conservation requirement, Equation 1.11c, to a unit length of the rod for the steady-state condition, $\dot{E}'_{\text{in}} - \dot{E}'_{\text{out}} + \dot{E}'_{\text{gen}} = 0$. Hence $q'_r(0) - q'_r(r_o) = -\dot{q}_1(\pi r_o^2)$.

PROBLEM 2.23

KNOWN: Temperature distribution in a one-dimensional wall with prescribed thickness and thermal conductivity.

FIND: (a) The heat generation rate, \dot{q} , in the wall, (b) Heat fluxes at the wall faces and relation to \dot{q} .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat flow, (3) Constant properties.

ANALYSIS: (a) The appropriate form of the heat equation for steady-state, one-dimensional conditions with constant properties is Eq. 2.19 re-written as

$$\dot{q} = -k \frac{d}{dx} \left[\frac{dT}{dx} \right]$$

Substituting the prescribed temperature distribution,

$$\dot{q} = -k \frac{d}{dx} \left[\frac{d}{dx} (a + bx^2) \right] = -k \frac{d}{dx} [2bx] = -2bk$$

$$\dot{q} = -2 \left(-2000^\circ\text{C}/\text{m}^2 \right) \times 50 \text{ W}/\text{m} \cdot \text{K} = 2.0 \times 10^5 \text{ W}/\text{m}^3.$$

<

(b) The heat fluxes at the wall faces can be evaluated from Fourier's law,

$$q_x''(x) = -k \left. \frac{dT}{dx} \right|_x.$$

Using the temperature distribution $T(x)$ to evaluate the gradient, find

$$q_x''(x) = -k \frac{d}{dx} [a + bx^2] = -2kbx.$$

The fluxes at $x = 0$ and $x = L$ are then

$$q_x''(0) = 0$$

<

$$q_x''(L) = -2kbL = -2 \times 50 \text{ W}/\text{m} \cdot \text{K} \left(-2000^\circ\text{C}/\text{m}^2 \right) \times 0.050 \text{ m}$$

$$q_x''(L) = 10,000 \text{ W}/\text{m}^2.$$

<

COMMENTS: From an overall energy balance on the wall, it follows that, for a unit area,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0 \quad q_x''(0) - q_x''(L) + \dot{q}L = 0$$

$$\dot{q} = \frac{q_x''(L) - q_x''(0)}{L} = \frac{10,000 \text{ W}/\text{m}^2 - 0}{0.050 \text{ m}} = 2.0 \times 10^5 \text{ W}/\text{m}^3.$$

PROBLEM 2.24

KNOWN: Wall thickness, thermal conductivity, temperature distribution, and fluid temperature.

FIND: (a) Surface heat rates and rate of change of wall energy storage per unit area, and (b) Convection coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x , (2) Constant k .

ANALYSIS: (a) From Fourier's law,

$$q''_x = -k \frac{\partial T}{\partial x} = (200 - 60x) \cdot k$$

$$q''_{in} = q''_{x=0} = 200 \frac{^\circ\text{C}}{\text{m}} \times 1 \frac{\text{W}}{\text{m} \cdot \text{K}} = 200 \text{ W/m}^2 \quad <$$

$$q''_{out} = q''_{x=L} = (200 - 60 \times 0.3) \frac{^\circ\text{C}}{\text{m}} \times 1 \text{ W/m} \cdot \text{K} = 182 \text{ W/m}^2. \quad <$$

Applying an energy balance to a control volume about the wall, Eq. 1.11c,

$$\dot{E}''_{in} - \dot{E}''_{out} = \dot{E}''_{st}$$

$$\dot{E}''_{st} = q''_{in} - q''_{out} = 18 \text{ W/m}^2. \quad <$$

(b) Applying a surface energy balance at $x = L$,

$$q''_{out} = h [T(L) - T_\infty]$$

$$h = \frac{q''_{out}}{T(L) - T_\infty} = \frac{182 \text{ W/m}^2}{(142.7 - 100)^\circ\text{C}}$$

$$h = 4.3 \text{ W/m}^2 \cdot \text{K}. \quad <$$

COMMENTS: (1) From the heat equation,

$$(\partial T / \partial t) = (k / \rho c_p) \partial^2 T / \partial x^2 = 60 (k / \rho c_p),$$

it follows that the temperature is increasing with time at every point in the wall.

(2) The value of h is small and is typical of free convection in a gas.

PROBLEM 2.25

KNOWN: Analytical expression for the steady-state temperature distribution of a plane wall experiencing uniform volumetric heat generation \dot{q} while convection occurs at both of its surfaces.

FIND: (a) Sketch the temperature distribution, $T(x)$, and identify significant physical features, (b) Determine \dot{q} , (c) Determine the surface heat fluxes, $q''_{x}(-L)$ and $q''_{x}(+L)$; how are these fluxes related to the generation rate; (d) Calculate the convection coefficients at the surfaces $x = L$ and $x = +L$, (e) Obtain an expression for the heat flux distribution, $q''_{x}(x)$; explain significant features of the distribution; (f) If the source of heat generation is suddenly deactivated ($\dot{q} = 0$), what is the rate of change of energy stored at this instant; (g) Determine the temperature that the wall will reach eventually with $\dot{q} = 0$; determine the energy that must be removed by the fluid per unit area of the wall to reach this state.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform volumetric heat generation, (3) Constant properties.

ANALYSIS: (a) Using the analytical expression in the Workspace of IHT, the temperature distribution appears as shown below. The significant features include (1) parabolic shape, (2) maximum does not occur at the mid-plane, $T(-5.25 \text{ mm}) = 83.3^\circ\text{C}$, (3) the gradient at the $x = +L$ surface is greater than at $x = -L$. Find also that $T(-L) = 78.2^\circ\text{C}$ and $T(+L) = 69.8^\circ\text{C}$ for use in part (d).

(b) Substituting the temperature distribution expression into the appropriate form of the heat diffusion equation, Eq. 2.19, the rate of volumetric heat generation can be determined.

$$\frac{d}{dx} \left(\frac{dT}{dx} \right) + \frac{\dot{q}}{k} = 0 \quad \text{where} \quad T(x) = a + bx + cx^2$$

$$\frac{d}{dx} (0 + b + 2cx) + \frac{\dot{q}}{k} = (0 + 2c) + \frac{\dot{q}}{k} = 0$$

Continued

PROBLEM 2.25 (Cont.)

$$\dot{q} = -2ck = -2\left(-2 \times 10^4 \text{ }^\circ\text{C} / \text{m}^2\right) 5 \text{ W} / \text{m} \cdot \text{K} = 2 \times 10^5 \text{ W} / \text{m}^3 \quad <$$

(c) The heat fluxes at the two boundaries can be determined using Fourier's law and the temperature distribution expression.

$$q_x''(x) = -k \frac{dT}{dx} \quad \text{where} \quad T(x) = a + bx + cx^2$$

$$q_x''(-L) = -k[0 + b + 2cx]_{x=-L} = -[b - 2cL]k$$

$$q_x''(-L) = -\left[-210^\circ\text{C} / \text{m} - 2\left(-2 \times 10^4 \text{ }^\circ\text{C} / \text{m}^2\right) 0.020 \text{ m}\right] \times 5 \text{ W} / \text{m} \cdot \text{K} = -2950 \text{ W} / \text{m}^2 \quad <$$

$$q_x''(+L) = -(b + 2cL)k = +5050 \text{ W} / \text{m}^2 \quad <$$

From an overall energy balance on the wall as shown in the sketch below, $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = 0$,

$$+q_x''(-L) - q_x''(+L) + 2\dot{q}L = 0 \quad \text{or} \quad -2950 \text{ W} / \text{m}^2 - 5050 \text{ W} / \text{m}^2 + 8000 \text{ W} / \text{m}^2 = 0$$

where $2\dot{q}L = 2 \times 2 \times 10^5 \text{ W} / \text{m}^3 \times 0.020 \text{ m} = 8000 \text{ W} / \text{m}^2$, so the equality is satisfied

Part (c) Overall energy balance

Part (d) Surface energy balances

(d) The convection coefficients, h_l and h_r , for the left- and right-hand boundaries ($x = -L$ and $x = +L$, respectively), can be determined from the convection heat fluxes that are equal to the conduction fluxes at the boundaries. See the surface energy balances in the sketch above. See also part (a) result for $T(-L)$ and $T(+L)$.

$$q_{\text{conv},l}'' = q_x''(-L)$$

$$h_l [T_\infty - T(-L)] = h_l [20 - 78.2] \text{ K} = -2950 \text{ W} / \text{m}^2 \quad h_l = 51 \text{ W} / \text{m}^2 \cdot \text{K} \quad <$$

$$q_{\text{conv},r}'' = q_x''(+L)$$

$$h_r [T(+L) - T_\infty] = h_r [69.8 - 20] \text{ K} = +5050 \text{ W} / \text{m}^2 \quad h_r = 101 \text{ W} / \text{m}^2 \cdot \text{K} \quad <$$

(e) The expression for the heat flux distribution can be obtained from Fourier's law with the temperature distribution

$$q_x''(x) = -k \frac{dT}{dx} = -k[0 + b + 2cx]$$

$$q_x''(x) = -5 \text{ W} / \text{m} \cdot \text{K} \left[-210^\circ\text{C} / \text{m} + 2\left(-2 \times 10^4 \text{ }^\circ\text{C} / \text{m}^2\right) x \right] = 1050 + 2 \times 10^5 x \quad <$$

Continued

PROBLEM 2.25 (Cont.)

The distribution is linear with the x -coordinate. The maximum temperature will occur at the location where $q_x''(x_{\max}) = 0$,

$$x_{\max} = -\frac{1050 \text{ W/m}^2}{2 \times 10^5 \text{ W/m}^3} = -5.25 \times 10^{-3} \text{ m} = -5.25 \text{ mm} \quad <$$

(f) If the source of the heat generation is suddenly deactivated so that $\dot{q} = 0$, the appropriate form of the heat diffusion equation for the ensuing transient conduction is

$$k \frac{\partial}{\partial x} \left(\frac{\partial T}{\partial x} \right) = \rho c_p \frac{\partial T}{\partial t}$$

At the instant this occurs, the temperature distribution is still $T(x) = a + bx + cx^2$. The right-hand term represents the rate of energy storage per unit volume,

$$\dot{E}_{\text{st}}'' = k \frac{\partial}{\partial x} [0 + b + 2cx] = k [0 + 2c] = 5 \text{ W/m} \cdot \text{K} \times 2 \left(-2 \times 10^4 \text{ }^\circ\text{C/m}^2 \right) = -2 \times 10^5 \text{ W/m}^3 \quad <$$

(g) With no heat generation, the wall will eventually ($t \rightarrow \infty$) come to equilibrium with the fluid, $T(x, \infty) = T_\infty = 20^\circ\text{C}$. To determine the energy that must be removed from the wall to reach this state, apply the conservation of energy requirement over an interval basis, Eq. 1.11b. The “initial” state is that corresponding to the steady-state temperature distribution, T_i , and the “final” state has $T_f = 20^\circ\text{C}$. We’ve used T_∞ as the reference condition for the energy terms.

$$E_{\text{in}}'' - E_{\text{out}}'' = \Delta E_{\text{st}}'' = E_f'' - E_i'' \quad \text{with} \quad E_{\text{in}}'' = 0.$$

$$E_{\text{out}}'' = c_p \int_{-L}^{+L} (T_i - T_\infty) dx$$

$$E_{\text{out}}'' = \rho c_p \int_{-L}^{+L} \left[a + bx + cx^2 - T_\infty \right] dx = \rho c_p \left[ax + bx^2/2 + cx^3/3 - T_\infty x \right]_{-L}^{+L}$$

$$E_{\text{out}}'' = \rho c_p \left[2aL + 0 + 2cL^3/3 - 2T_\infty L \right]$$

$$E_{\text{out}}'' = 2600 \text{ kg/m}^3 \times 800 \text{ J/kg} \cdot \text{K} \left[2 \times 82^\circ\text{C} \times 0.020 \text{ m} + 2 \left(-2 \times 10^4 \text{ }^\circ\text{C/m}^2 \right) (0.020 \text{ m})^3 / 3 - 2(20^\circ\text{C}) 0.020 \text{ m} \right]$$

$$E_{\text{out}}'' = 4.94 \times 10^6 \text{ J/m}^2 \quad <$$

COMMENTS: (1) In part (a), note that the temperature gradient is larger at $x = +L$ than at $x = -L$. This is consistent with the results of part (c) in which the conduction heat fluxes are evaluated.

Continued

PROBLEM 2.25 (Cont.)

(2) In evaluating the conduction heat fluxes, $q_x''(x)$, it is important to recognize that this flux is in the positive x -direction. See how this convention is used in formulating the energy balance in part (c).

(3) It is good practice to represent energy balances with a schematic, clearly defining the system or surface, showing the CV or CS with dashed lines, and labeling the processes. Review again the features in the schematics for the energy balances of parts (c & d).

(4) Re-writing the heat diffusion equation introduced in part (b) as

$$-\frac{d}{dx}\left(-k \frac{dT}{dx}\right) + \dot{q} = 0$$

recognize that the term in parenthesis is the heat flux. From the differential equation, note that if the differential of this term is a constant (\dot{q}/k), then the term must be a linear function of the x -coordinate. This agrees with the analysis of part (e).

(5) In part (f), we evaluated \dot{E}_{st} , the rate of energy change stored in the wall at the instant the volumetric heat generation was deactivated. Did you notice that $\dot{E}_{st} = -2 \times 10^5 \text{ W/m}^3$ is the same value of the deactivated \dot{q} ? How do you explain this?

PROBLEM 2.26

KNOWN: Steady-state conduction with uniform internal energy generation in a plane wall; temperature distribution has quadratic form. Surface at $x=0$ is prescribed and boundary at $x=L$ is insulated.

FIND: (a) Calculate the internal energy generation rate, \dot{q} , by applying an overall energy balance to the wall, (b) Determine the coefficients a , b , and c , by applying the boundary conditions to the prescribed form of the temperature distribution; plot the temperature distribution and label as Case 1, (c) Determine new values for a , b , and c for conditions when the convection coefficient is halved, and the generation rate remains unchanged; plot the temperature distribution and label as Case 2; (d) Determine new values for a , b , and c for conditions when the generation rate is doubled, and the convection coefficient remains unchanged ($h = 500 \text{ W/m}^2\cdot\text{K}$); plot the temperature distribution and label as Case 3.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with constant properties and uniform internal generation, and (3) Boundary at $x=L$ is adiabatic.

ANALYSIS: (a) The internal energy generation rate can be calculated from an overall energy balance on the wall as shown in the schematic below.

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' + \dot{E}_{\text{gen}}'' = 0 \quad \text{where} \quad \dot{E}_{\text{in}}'' = q_{\text{conv}}''$$

$$h(T_\infty - T_o) + \dot{q}L = 0 \quad (1)$$

$$\dot{q} = -h(T_\infty - T_o)/L = -500 \text{ W/m}^2 \cdot \text{K} (20 - 120)^\circ\text{C} / 0.050 \text{ m} = 1.0 \times 10^6 \text{ W/m}^3 <$$

(b) The coefficients of the temperature distribution, $T(x) = a + bx + cx^2$, can be evaluated by applying the boundary conditions at $x=0$ and $x=L$. See Table 2.2 for representation of the boundary conditions, and the schematic above for the relevant surface energy balances.

Boundary condition at $x=0$, convection surface condition

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' = q_{\text{conv}}'' - q_x''(0) = 0 \quad \text{where} \quad q_x''(0) = -k \left. \frac{dT}{dx} \right|_{x=0}$$

$$h(T_\infty - T_o) - \left[-k(0 + b + 2cx)_{x=0} \right] = 0$$

Continued

PROBLEM 2.26 (Cont.)

$$b = -h(T_\infty - T_o)/k = -500 \text{ W/m}^2 \cdot \text{K} (20 - 120)^\circ\text{C} / 5 \text{ W/m} \cdot \text{K} = 1.0 \times 10^4 \text{ K/m} \quad (2) <$$

Boundary condition at $x = L$, adiabatic or insulated surface

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = -q_x''(L) = 0 \quad \text{where} \quad q_x''(L) = -k \left. \frac{dT}{dx} \right|_{x=L}$$

$$k[0 + b + 2cx]_{x=L} = 0 \quad (3)$$

$$c = -b/2L = -1.0 \times 10^4 \text{ K/m} / (2 \times 0.050 \text{ m}) = -1.0 \times 10^5 \text{ K/m}^2 \quad <$$

Since the surface temperature at $x = 0$ is known, $T(0) = T_o = 120^\circ\text{C}$, find

$$T(0) = 120^\circ\text{C} = a + b \cdot 0 + c \cdot 0 \quad \text{or} \quad a = 120^\circ\text{C} \quad (4) <$$

Using the foregoing coefficients with the expression for $T(x)$ in the Workspace of IHT, the temperature distribution can be determined and is plotted as Case 1 in the graph below.

(c) Consider Case 2 when the convection coefficient is halved, $h_2 = h/2 = 250 \text{ W/m}^2 \cdot \text{K}$, $\dot{q} = 1 \times 10^6 \text{ W/m}^3$ and other parameters remain unchanged except that $T_o \neq 120^\circ\text{C}$. We can determine a , b , and c for the temperature distribution expression by repeating the analyses of parts (a) and (b).

Overall energy balance on the wall, see Eqs. (1,4)

$$a = T_o = \dot{q}L/h + T_\infty = 1 \times 10^6 \text{ W/m}^3 \times 0.050 \text{ m} / 250 \text{ W/m}^2 \cdot \text{K} + 20^\circ\text{C} = 220^\circ\text{C} \quad <$$

Surface energy balance at $x = 0$, see Eq. (2)

$$b = -h(T_\infty - T_o)/k = -250 \text{ W/m}^2 \cdot \text{K} (20 - 220)^\circ\text{C} / 5 \text{ W/m} \cdot \text{K} = 1.0 \times 10^4 \text{ K/m} \quad <$$

Surface energy balance at $x = L$, see Eq. (3)

$$c = -b/2L = -1.0 \times 10^4 \text{ K/m} / (2 \times 0.050 \text{ m}) = -1.0 \times 10^5 \text{ K/m}^2 \quad <$$

The new temperature distribution, $T_2(x)$, is plotted as Case 2 below.

(d) Consider Case 3 when the internal energy volumetric generation rate is doubled, $\dot{q}_3 = 2\dot{q} = 2 \times 10^6 \text{ W/m}^3$, $h = 500 \text{ W/m}^2 \cdot \text{K}$, and other parameters remain unchanged except that $T_o \neq 120^\circ\text{C}$. Following the same analysis as part (c), the coefficients for the new temperature distribution, $T(x)$, are

$$a = 220^\circ\text{C} \quad b = 2 \times 10^4 \text{ K/m} \quad c = -2 \times 10^5 \text{ K/m}^2 \quad <$$

and the distribution is plotted as Case 3 below.

Continued

PROBLEM 2.26 (Cont.)

COMMENTS: Note the following features in the family of temperature distributions plotted above. The temperature gradients at $x = L$ are zero since the boundary is insulated (adiabatic) for all cases. The shapes of the distributions are all quadratic, with the maximum temperatures at the insulated boundary.

By halving the convection coefficient for Case 2, we expect the surface temperature T_o to increase relative to the Case 1 value, since the same heat flux is removed from the wall ($\dot{q}L$) but the convection resistance has increased.

By doubling the generation rate for Case 3, we expect the surface temperature T_o to increase relative to the Case 1 value, since double the amount of heat flux is removed from the wall ($2\dot{q}L$).

Can you explain why T_o is the same for Cases 2 and 3, yet the insulated boundary temperatures are quite different? Can you explain the relative magnitudes of $T(L)$ for the three cases?

PROBLEM 2.27

KNOWN: Temperature distribution and distribution of heat generation in central layer of a solar pond.

FIND: (a) Heat fluxes at lower and upper surfaces of the central layer, (b) Whether conditions are steady or transient, (c) Rate of thermal energy generation for the entire central layer.

SCHEMATIC:

ASSUMPTIONS: (1) Central layer is stagnant, (2) One-dimensional conduction, (3) Constant properties

ANALYSIS: (a) The desired fluxes correspond to conduction fluxes in the central layer at the lower and upper surfaces. A general form for the conduction flux is

$$q''_{\text{cond}} = -k \frac{\partial T}{\partial x} = -k \left[\frac{A}{ka} e^{-ax} + B \right].$$

Hence,

$$q_1'' = q''_{\text{cond}}(x=L) = -k \left[\frac{A}{ka} e^{-aL} + B \right] \quad q_u'' = q''_{\text{cond}}(x=0) = -k \left[\frac{A}{ka} + B \right]. \quad <$$

(b) Conditions are steady if $\partial T / \partial t = 0$. Applying the heat equation,

$$\frac{\partial^2 T}{\partial x^2} + \frac{\dot{q}}{k} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad -\frac{A}{k} e^{-ax} + \frac{A}{k} e^{-ax} = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

Hence conditions are *steady* since

$$\partial T / \partial t = 0 \quad (\text{for all } 0 \leq x \leq L). \quad <$$

(c) For the central layer, the energy generation is

$$\begin{aligned} \dot{E}_g'' &= \int_0^L \dot{q} \, dx = A \int_0^L e^{-ax} \, dx \\ \dot{E}_g &= -\frac{A}{a} e^{-ax} \Big|_0^L = -\frac{A}{a} (e^{-aL} - 1) = \frac{A}{a} (1 - e^{-aL}). \end{aligned} \quad <$$

Alternatively, from an overall energy balance,

$$\begin{aligned} q_2'' - q_1'' + \dot{E}_g'' &= 0 \quad \dot{E}_g'' = q_1'' - q_2'' = (-q''_{\text{cond}}(x=0)) - (-q''_{\text{cond}}(x=L)) \\ \dot{E}_g &= k \left[\frac{A}{ka} + B \right] - k \left[\frac{A}{ka} e^{-aL} + B \right] = \frac{A}{a} (1 - e^{-aL}). \end{aligned}$$

COMMENTS: Conduction is in the negative x-direction, necessitating use of minus signs in the above energy balance.

PROBLEM 2.28

KNOWN: Temperature distribution in a semi-transparent medium subjected to radiative flux.

FIND: (a) Expressions for the heat flux at the front and rear surfaces, (b) Heat generation rate $\dot{q}(x)$,
(c) Expression for absorbed radiation per unit surface area in terms of A , a , B , C , L , and k .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in medium, (3) Constant properties, (4) All laser irradiation is absorbed and can be characterized by an internal volumetric heat generation term $\dot{q}(x)$.

ANALYSIS: (a) Knowing the temperature distribution, the surface heat fluxes are found using Fourier's law,

$$q''_x = -k \left[\frac{dT}{dx} \right] = -k \left[-\frac{A}{ka^2} (-a) e^{-ax} + B \right]$$

$$\text{Front Surface, } x=0: \quad q''_x(0) = -k \left[+\frac{A}{ka} \cdot 1 + B \right] = -\left[\frac{A}{a} + kB \right] <$$

$$\text{Rear Surface, } x=L: \quad q''_x(L) = -k \left[+\frac{A}{ka} e^{-aL} + B \right] = -\left[\frac{A}{a} e^{-aL} + kB \right]. <$$

(b) The heat diffusion equation for the medium is

$$\frac{d}{dx} \left(\frac{dT}{dx} \right) + \frac{\dot{q}}{k} = 0 \quad \text{or} \quad \dot{q} = -k \frac{d}{dx} \left(\frac{dT}{dx} \right)$$

$$\dot{q}(x) = -k \frac{d}{dx} \left[+\frac{A}{ka} e^{-ax} + B \right] = A e^{-ax}. <$$

(c) Performing an energy balance on the medium,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0$$

recognize that \dot{E}_g represents the absorbed irradiation. On a unit area basis

$$\dot{E}_g'' = -\dot{E}_{\text{in}}'' + \dot{E}_{\text{out}}'' = -q''_x(0) + q''_x(L) = +\frac{A}{a} (1 - e^{-aL}). <$$

Alternatively, evaluate \dot{E}_g'' by integration over the volume of the medium,

$$\dot{E}_g'' = \int_0^L \dot{q}(x) dx = \int_0^L A e^{-ax} dx = -\frac{A}{a} \left[e^{-ax} \right]_0^L = \frac{A}{a} (1 - e^{-aL}).$$

PROBLEM 2.29

KNOWN: Steady-state temperature distribution in a one-dimensional wall of thermal conductivity, $T(x) = Ax^3 + Bx^2 + Cx + D$.

FIND: Expressions for the heat generation rate in the wall and the heat fluxes at the two wall faces ($x = 0, L$).

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat flow, (3) Homogeneous medium.

ANALYSIS: The appropriate form of the heat diffusion equation for these conditions is

$$\frac{d^2T}{dx^2} + \frac{\dot{q}}{k} = 0 \quad \text{or} \quad \dot{q} = -k \frac{d^2T}{dx^2}.$$

Hence, the generation rate is

$$\dot{q} = -k \frac{d}{dx} \left[\frac{dT}{dx} \right] = -k \frac{d}{dx} [3Ax^2 + 2Bx + C + 0]$$

$$\dot{q} = -k[6Ax + 2B] \quad <$$

which is linear with the coordinate x . The heat fluxes at the wall faces can be evaluated from Fourier's law,

$$q_x'' = -k \frac{dT}{dx} = -k[3Ax^2 + 2Bx + C]$$

using the expression for the temperature gradient derived above. Hence, the heat fluxes are:

Surface $x=0$:

$$q_x''(0) = -kC \quad <$$

Surface $x=L$:

$$q_x''(L) = -k[3AL^2 + 2BL + C]. \quad <$$

COMMENTS: (1) From an overall energy balance on the wall, find

$$\dot{E}_{in}'' - \dot{E}_{out}'' + \dot{E}_g'' = 0$$

$$q_x''(0) - q_x''(L) + \dot{E}_g'' = (-kC) - (-k)[3AL^2 + 2BL + C] + \dot{E}_g'' = 0$$

$$\dot{E}_g'' = -3AkL^2 - 2BkL.$$

From integration of the volumetric heat rate, we can also find \dot{E}_g'' as

$$\dot{E}_g'' = \int_0^L \dot{q}(x) dx = \int_0^L -k[6Ax + 2B] dx = -k \left[3Ax^2 + 2Bx \right]_0^L$$

$$\dot{E}_g'' = -3AkL^2 - 2BkL.$$

PROBLEM 2.30

KNOWN: Plane wall with no internal energy generation.

FIND: Determine whether the prescribed temperature distribution is possible; explain your reasoning. With the temperatures $T(0) = 0^\circ\text{C}$ and $T_\infty = 20^\circ\text{C}$ fixed, compute and plot the temperature $T(L)$ as a function of the convection coefficient for the range $10 \leq h \leq 100 \text{ W/m}^2\cdot\text{K}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) No internal energy generation, (3) Constant properties, (4) No radiation exchange at the surface $x = L$, and (5) Steady-state conditions.

ANALYSIS: (a) Is the prescribed temperature distribution possible? If so, the energy balance at the surface $x = L$ as shown above in the Schematic, must be satisfied.

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q''_x(L) - q''_{cv} = 0 \quad (1,2)$$

where the conduction and convection heat fluxes are, respectively,

$$q''_x(L) = -k \left. \frac{dT}{dx} \right|_{x=L} = -k \frac{T(L) - T(0)}{L} = -4.5 \text{ W/m}\cdot\text{K} \times (120 - 0)^\circ\text{C} / 0.18 \text{ m} = -3000 \text{ W/m}^2$$

$$q''_{cv} = h [T(L) - T_\infty] = 30 \text{ W/m}^2\cdot\text{K} \times (120 - 20)^\circ\text{C} = 3000 \text{ W/m}^2$$

Substituting the heat flux values into Eq. (2), find $(-3000) - (3000) \neq 0$ and therefore, the temperature distribution is not possible.

(b) With $T(0) = 0^\circ\text{C}$ and $T_\infty = 20^\circ\text{C}$, the temperature at the surface $x = L$, $T(L)$, can be determined from an overall energy balance on the wall as shown above in the Schematic,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q''_x(0) - q''_{cv} = 0 \quad -k \frac{T(L) - T(0)}{L} - h [T(L) - T_\infty] = 0$$

$$-4.5 \text{ W/m}\cdot\text{K} [T(L) - 0^\circ\text{C}] / 0.18 \text{ m} - 30 \text{ W/m}^2\cdot\text{K} [T(L) - 20^\circ\text{C}] = 0$$

$$T(L) = 10.9^\circ\text{C}$$

Using this same analysis, $T(L)$ as a function of the convection coefficient can be determined and plotted. We don't expect $T(L)$ to be linearly dependent upon h . Note that as h increases to larger values, $T(L)$ approaches T_∞ . To what value will $T(L)$ approach as h decreases?

PROBLEM 2.31

KNOWN: Coal pile of prescribed depth experiencing uniform volumetric generation with convection, absorbed irradiation and emission on its upper surface.

FIND: (a) The appropriate form of the heat diffusion equation (HDE) and whether the prescribed temperature distribution satisfies this HDE; conditions at the bottom of the pile, $x = 0$; sketch of the temperature distribution with labeling of key features; (b) Expression for the conduction heat rate at the location $x = L$; expression for the surface temperature T_s based upon a surface energy balance at $x = L$; evaluate T_s and $T(0)$ for the prescribed conditions; (c) Based upon typical daily averages for G_s and h , compute and plot T_s and $T(0)$ for (1) $h = 5 \text{ W/m}^2 \cdot \text{K}$ with $50 \leq G_s \leq 500 \text{ W/m}^2$, (2) $G_s = 400 \text{ W/m}^2$ with $5 \leq h \leq 50 \text{ W/m}^2 \cdot \text{K}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Uniform volumetric heat generation, (3) Constant properties, (4) Negligible irradiation from the surroundings, and (5) Steady-state conditions.

PROPERTIES: Table A.3, Coal (300K): $k = 0.26 \text{ W/m} \cdot \text{K}$

ANALYSIS: (a) For one-dimensional, steady-state conduction with uniform volumetric heat generation and constant properties the heat diffusion equation (HDE) follows from Eq. 2.20,

$$\frac{d}{dx} \left(\frac{dT}{dx} \right) + \frac{\dot{q}}{k} = 0 \quad (1)$$

Substituting the temperature distribution into the HDE, Eq. (1),

$$T(x) = T_s + \frac{\dot{q}L^2}{2k} \left(1 - \frac{x^2}{L^2} \right) \quad \frac{d}{dx} \left[0 + \frac{\dot{q}L^2}{2k} \left(0 - \frac{2x}{L^2} \right) \right] + \frac{\dot{q}}{k} = 0 \quad (2,3)$$

we find that it does indeed satisfy the HDE for all values of x .

From Eq. (2), note that the temperature distribution must be quadratic, with maximum value at $x = 0$. At $x = 0$, the heat flux is

$$q''_x(0) = -k \left(\frac{dT}{dx} \right)_{x=0} = -k \left[0 + \frac{\dot{q}L^2}{2k} \left(0 - \frac{2x}{L^2} \right) \right]_{x=0} = 0$$

so that the gradient at $x = 0$ is zero. Hence, the bottom is insulated.

(b) From an overall energy balance on the pile, the conduction heat flux at the surface must be

$$q''_x(L) = \dot{E}_g = \dot{q}L$$

Continued...

PROBLEM 2.31 (Cont.)

From a surface energy balance per unit area shown in the Schematic above,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0 \quad q_x''(L) - q_{\text{conv}}'' + G_{S,\text{abs}} - E = 0$$

$$\dot{q}L - h(T_s - T_\infty) + 0.95G_S - \varepsilon\sigma T_s^4 = 0 \quad (4)$$

$$20 \text{ W/m}^3 \times 1 \text{ m} - 5 \text{ W/m}^2 \cdot \text{K} (T_s - 298 \text{ K}) + 0.95 \times 400 \text{ W/m}^2 - 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 T_s^4 = 0$$

$$T_s = 295.7 \text{ K} = 22.7^\circ\text{C}$$

From Eq. (2) with $x = 0$, find

$$T(0) = T_s + \frac{\dot{q}L^2}{2k} = 22.7^\circ\text{C} + \frac{20 \text{ W/m}^3 \times (1 \text{ m})^2}{2 \times 0.26 \text{ W/m} \cdot \text{K}} = 61.1^\circ\text{C} \quad (5)$$

where the thermal conductivity for coal was obtained from Table A.3.

(c) Two plots are generated using Eq. (4) and (5) for T_s and $T(0)$, respectively; (1) with $h = 5 \text{ W/m}^2 \cdot \text{K}$ for $50 \leq G_S \leq 500 \text{ W/m}^2$ and (2) with $G_S = 400 \text{ W/m}^2$ for $5 \leq h \leq 50 \text{ W/m}^2 \cdot \text{K}$.

From the T vs. h plot with $G_S = 400 \text{ W/m}^2$, note that the convection coefficient does not have a major influence on the surface or bottom coal pile temperatures. From the T vs. G_S plot with $h = 5 \text{ W/m}^2 \cdot \text{K}$, note that the solar irradiation has a very significant effect on the temperatures. The fact that T_s is less than the ambient air temperature, T_∞ , and, in the case of very low values of G_S , below freezing, is a consequence of the large magnitude of the emissive power E .

COMMENTS: In our analysis we ignored irradiation from the sky, an environmental radiation effect you'll consider in Chapter 12. Treated as large isothermal surroundings, $G_{\text{sky}} = \sigma T_{\text{sky}}^4$ where $T_{\text{sky}} = -30^\circ\text{C}$ for very clear conditions and nearly air temperature for cloudy conditions. For low G_S conditions we should consider G_{sky} , the effect of which will be to predict higher values for T_s and $T(0)$.

PROBLEM 2.32

KNOWN: Cylindrical system with negligible temperature variation in the r, z directions.

FIND: (a) Heat equation beginning with a properly defined control volume, (b) Temperature distribution $T(\phi)$ for steady-state conditions with no internal heat generation and constant properties, (c) Heat rate for Part (b) conditions.

SCHEMATIC:

ASSUMPTIONS: (1) T is independent of r, z , (2) $\Delta r = (r_o - r_i) \ll r_i$.

ANALYSIS: (a) Define the control volume as $V = r_i d\phi \cdot \Delta r \cdot L$ where L is length normal to page. Apply the conservation of energy requirement, Eq. 1.11c,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st} \quad q_\phi - q_{\phi+d\phi} + \dot{q}V = \rho V c \frac{\partial T}{\partial t} \quad (1,2)$$

where
$$q_\phi = -k(\Delta r \cdot L) \frac{\partial T}{r_i \partial \phi} \quad q_{\phi+d\phi} = q_\phi + \frac{\partial}{\partial \phi}(q_\phi) d\phi. \quad (3,4)$$

Eqs. (3) and (4) follow from Fourier's law, Eq. 2.1, and from Eq. 2.11, respectively. Combining Eqs. (3) and (4) with Eq. (2) and canceling like terms, find

$$\frac{1}{r_i^2} \frac{\partial}{\partial \phi} \left(k \frac{\partial T}{\partial \phi} \right) + \dot{q} = \rho c \frac{\partial T}{\partial t}. \quad (5) <$$

Since temperature is independent of r and z , this form agrees with Eq. 2.24.

(b) For steady-state conditions with $\dot{q} = 0$, the heat equation, (5), becomes

$$\frac{d}{d\phi} \left[k \frac{dT}{d\phi} \right] = 0. \quad (6)$$

With constant properties, it follows that $dT/d\phi$ is constant which implies $T(\phi)$ is linear in ϕ . That is,

$$\frac{dT}{d\phi} = \frac{T_2 - T_1}{\phi_2 - \phi_1} = + \frac{1}{\pi} (T_2 - T_1) \quad \text{or} \quad T(\phi) = T_1 + \frac{1}{\pi} (T_2 - T_1) \phi. \quad (7,8) <$$

(c) The heat rate for the conditions of Part (b) follows from Fourier's law, Eq. (3), using the temperature gradient of Eq. (7). That is,

$$q_\phi = -k(\Delta r \cdot L) \frac{1}{r_i} \left[+ \frac{1}{\pi} (T_2 - T_1) \right] = -k \left[\frac{r_o - r_i}{\pi r_i} \right] L (T_2 - T_1). \quad (9) <$$

COMMENTS: Note the expression for the temperature gradient in Fourier's law, Eq. (3), is $\partial T / r_i \partial \phi$ not $\partial T / \partial \phi$. For the conditions of Parts (b) and (c), note that q_ϕ is independent of ϕ ; this is first indicated by Eq. (6) and confirmed by Eq. (9).

PROBLEM 2.33

KNOWN: Heat diffusion with internal heat generation for one-dimensional cylindrical, radial coordinate system.

FIND: Heat diffusion equation.

SCHEMATIC:

ASSUMPTIONS: (1) Homogeneous medium.

ANALYSIS: Control volume has volume, $V = A_r \cdot dr = 2\pi \cdot dr \cdot 1$, with unit thickness normal to page. Using the conservation of energy requirement, Eq. 1.11c,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = \dot{E}_{st}$$

$$q_r - q_{r+dr} + \dot{q}V = \rho V c_p \frac{\partial T}{\partial t}.$$

Fourier's law, Eq. 2.1, for this one-dimensional coordinate system is

$$q_r = -kA_r \frac{\partial T}{\partial r} = -k \times 2\pi \cdot 1 \times \frac{\partial T}{\partial r}.$$

At the outer surface, $r + dr$, the conduction rate is

$$q_{r+dr} = q_r + \frac{\partial}{\partial r}(q_r)dr = q_r + \frac{\partial}{\partial r} \left[-k \cdot 2\pi r \cdot \frac{\partial T}{\partial r} \right] dr.$$

Hence, the energy balance becomes

$$q_r - \left[q_r + \frac{\partial}{\partial r} \left[-k2\pi r \frac{\partial T}{\partial r} \right] dr \right] + \dot{q} \cdot 2\pi r dr = \rho \cdot 2\pi r dr \cdot c_p \frac{\partial T}{\partial t}$$

Dividing by the factor $2\pi r dr$, we obtain

$$\frac{1}{r} \frac{\partial}{\partial r} \left[kr \frac{\partial T}{\partial r} \right] + \dot{q} = \rho c_p \frac{\partial T}{\partial t}.$$

<

COMMENTS: (1) Note how the result compares with Eq. 2.24 when the terms for the ϕ, z coordinates are eliminated. (2) Recognize that we did not require \dot{q} and k to be independent of r .

PROBLEM 2.34

KNOWN: Heat diffusion with internal heat generation for one-dimensional spherical, radial coordinate system.

FIND: Heat diffusion equation.

SCHEMATIC:

ASSUMPTIONS: (1) Homogeneous medium.

ANALYSIS: Control volume has the volume, $V = A_r \cdot dr = 4\pi r^2 dr$. Using the conservation of energy requirement, Eq. 1.11c,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = \dot{E}_{st}$$

$$q_r - q_{r+dr} + \dot{q}V = \rho V c_p \frac{\partial T}{\partial t}.$$

Fourier's law, Eq. 2.1, for this coordinate system has the form

$$q_r = -kA_r \frac{\partial T}{\partial r} = -k \cdot 4\pi r^2 \cdot \frac{\partial T}{\partial r}.$$

At the outer surface, $r + dr$, the conduction rate is

$$q_{r+dr} = q_r + \frac{\partial}{\partial r}(q_r)dr = q_r + \frac{\partial}{\partial r} \left[-k \cdot 4\pi r^2 \cdot \frac{\partial T}{\partial r} \right] dr.$$

Hence, the energy balance becomes

$$q_r - \left[q_r + \frac{\partial}{\partial r} \left[-k \cdot 4\pi r^2 \cdot \frac{\partial T}{\partial r} \right] dr \right] + \dot{q} \cdot 4\pi r^2 dr = \rho \cdot 4\pi r^2 dr \cdot c_p \frac{\partial T}{\partial t}.$$

Dividing by the factor $4\pi r^2 dr$, we obtain

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left[kr^2 \frac{\partial T}{\partial r} \right] + \dot{q} = \rho c_p \frac{\partial T}{\partial t}.$$

<

COMMENTS: (1) Note how the result compares with Eq. 2.27 when the terms for the θ, ϕ directions are eliminated.

(2) Recognize that we did not require \dot{q} and k to be independent of the coordinate r .

PROBLEM 2.35

KNOWN: Three-dimensional system – described by cylindrical coordinates (r, ϕ, z) – experiences transient conduction and internal heat generation.

FIND: Heat diffusion equation.

SCHEMATIC: See also Fig. 2.9.

ASSUMPTIONS: (1) Homogeneous medium.

ANALYSIS: Consider the differential control volume identified above having a volume given as $V = dr \cdot r d\phi \cdot dz$. From the conservation of energy requirement,

$$q_r - q_{r+dr} + q_\phi - q_{\phi+d\phi} + q_z - q_{z+dz} + \dot{E}_g = \dot{E}_{st}. \quad (1)$$

The generation and storage terms, both representing volumetric phenomena, are

$$\dot{E}_g = \dot{q}V = \dot{q}(dr \cdot r d\phi \cdot dz) \quad \dot{E}_g = \rho V c \partial T / \partial t = \rho(dr \cdot r d\phi \cdot dz) c \partial T / \partial t. \quad (2,3)$$

Using a Taylor series expansion, we can write

$$q_{r+dr} = q_r + \frac{\partial}{\partial r}(q_r)dr, \quad q_{\phi+d\phi} = q_\phi + \frac{\partial}{\partial \phi}(q_\phi)d\phi, \quad q_{z+dz} = q_z + \frac{\partial}{\partial z}(q_z)dz. \quad (4,5,6)$$

Using Fourier's law, the expressions for the conduction heat rates are

$$q_r = -kA_r \partial T / \partial r = -k(r d\phi \cdot dz) \partial T / \partial r \quad (7)$$

$$q_\phi = -kA_\phi \partial T / r \partial \phi = -k(dr \cdot dz) \partial T / r \partial \phi \quad (8)$$

$$q_z = -kA_z \partial T / \partial z = -k(dr \cdot r d\phi) \partial T / \partial z. \quad (9)$$

Note from the above, right schematic that the gradient in the ϕ -direction is $\partial T / r \partial \phi$ and not $\partial T / \partial \phi$. Substituting Eqs. (2), (3) and (4), (5), (6) into Eq. (1),

$$-\frac{\partial}{\partial r}(q_r)dr - \frac{\partial}{\partial \phi}(q_\phi)d\phi - \frac{\partial}{\partial z}(q_z)dz + \dot{q} dr \cdot r d\phi \cdot dz = \rho(dr \cdot r d\phi \cdot dz) c \frac{\partial T}{\partial t}. \quad (10)$$

Substituting Eqs. (7), (8) and (9) for the conduction rates, find

$$\begin{aligned} -\frac{\partial}{\partial r} \left[-k(r d\phi \cdot dz) \frac{\partial T}{\partial r} \right] dr - \frac{\partial}{\partial \phi} \left[-k(dr dz) \frac{\partial T}{r \partial \phi} \right] d\phi - \frac{\partial}{\partial z} \left[-k(dr \cdot r d\phi) \frac{\partial T}{\partial z} \right] dz \\ + \dot{q} dr \cdot r d\phi \cdot dz = \rho(dr \cdot r d\phi \cdot dz) c \frac{\partial T}{\partial t}. \end{aligned} \quad (11)$$

Dividing Eq. (11) by the volume of the CV, Eq. 2.24 is obtained.

$$\frac{1}{r} \frac{\partial}{\partial r} \left[kr \frac{\partial T}{\partial r} \right] + \frac{1}{r^2} \frac{\partial}{\partial \phi} \left[k \frac{\partial T}{\partial \phi} \right] + \frac{\partial}{\partial z} \left[k \frac{\partial T}{\partial z} \right] + \dot{q} = \rho c \frac{\partial T}{\partial t} \quad <$$

PROBLEM 2.36

KNOWN: Three-dimensional system – described by spherical coordinates (r, ϕ, θ) – experiences transient conduction and internal heat generation.

FIND: Heat diffusion equation.

SCHEMATIC: See Figure 2.13.

ASSUMPTIONS: (1) Homogeneous medium.

ANALYSIS: The differential control volume is $V = dr \cdot r \sin \theta d\phi \cdot r d\theta$, and the conduction terms are identified in Figure 2.13. Conservation of energy requires

$$q_r - q_{r+dr} + q_\phi - q_{\phi+d\phi} + q_\theta - q_{\theta+d\theta} + \dot{E}_g = \dot{E}_{st}. \quad (1)$$

The generation and storage terms, both representing volumetric phenomena, are

$$\dot{E}_g = \dot{q}V = \dot{q}[dr \cdot r \sin \theta d\phi \cdot r d\theta] \quad \dot{E}_{st} = \rho V c \frac{\partial T}{\partial t} = \rho[dr \cdot r \sin \theta d\phi \cdot r d\theta] c \frac{\partial T}{\partial t}. \quad (2,3)$$

Using a Taylor series expansion, we can write

$$q_{r+dr} = q_r + \frac{\partial}{\partial r}(q_r)dr, \quad q_{\phi+d\phi} = q_\phi + \frac{\partial}{\partial \phi}(q_\phi)d\phi, \quad q_{\theta+d\theta} = q_\theta + \frac{\partial}{\partial \theta}(q_\theta)d\theta. \quad (4,5,6)$$

From Fourier's law, the conduction heat rates have the following forms.

$$q_r = -kA_r \partial T / \partial r = -k[r \sin \theta d\phi \cdot r d\theta] \partial T / \partial r \quad (7)$$

$$q_\phi = -kA_\phi \partial T / r \sin \theta \partial \phi = -k[dr \cdot r d\theta] \partial T / r \sin \theta \partial \phi \quad (8)$$

$$q_\theta = -kA_\theta \partial T / r \partial \theta = -k[dr \cdot r \sin \theta d\phi] \partial T / r \partial \theta. \quad (9)$$

Substituting Eqs. (2), (3) and (4), (5), (6) into Eq. (1), the energy balance becomes

$$-\frac{\partial}{\partial r}(q_r)dr - \frac{\partial}{\partial \phi}(q_\phi)d\phi - \frac{\partial}{\partial \theta}(q_\theta)d\theta + \dot{q}[dr \cdot r \sin \theta d\phi \cdot r d\theta] = \rho[dr \cdot r \sin \theta d\phi \cdot r d\theta] c \frac{\partial T}{\partial t} \quad (10)$$

Substituting Eqs. (7), (8) and (9) for the conduction rates, find

$$\begin{aligned} & -\frac{\partial}{\partial r} \left[-k[r \sin \theta d\phi \cdot r d\theta] \frac{\partial T}{\partial r} \right] dr - \frac{\partial}{\partial \phi} \left[-k[dr \cdot r d\theta] \frac{\partial T}{r \sin \theta \partial \phi} \right] d\phi \\ & - \frac{\partial}{\partial \theta} \left[-k[dr \cdot r \sin \theta d\phi] \frac{\partial T}{r \partial \theta} \right] d\theta + \dot{q}[dr \cdot r \sin \theta d\phi \cdot r d\theta] = \rho[dr \cdot r \sin \theta d\phi \cdot r d\theta] c \frac{\partial T}{\partial t} \end{aligned} \quad (11)$$

Dividing Eq. (11) by the volume of the control volume, V , Eq. 2.27 is obtained.

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left[kr^2 \frac{\partial T}{\partial r} \right] + \frac{1}{r^2 \sin^2 \theta} \frac{\partial}{\partial \phi} \left[k \frac{\partial T}{\partial \phi} \right] + \frac{1}{r^2 \sin \theta} \frac{\partial}{\partial \theta} \left[k \sin \theta \frac{\partial T}{\partial \theta} \right] + \dot{q} = \rho c \frac{\partial T}{\partial t}. \quad <$$

COMMENTS: Note how the temperature gradients in Eqs. (7) - (9) are formulated. The numerator is always ∂T while the denominator is the dimension of the control volume in the specified coordinate direction.

PROBLEM 2.37

KNOWN: Temperature distribution in steam pipe insulation.

FIND: Whether conditions are steady-state or transient. Manner in which heat flux and heat rate vary with radius.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in r , (2) Constant properties.

ANALYSIS: From Equation 2.24, the heat equation reduces to

$$\frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial T}{\partial r} \right) = \frac{1}{\alpha} \frac{\partial T}{\partial t}.$$

Substituting for $T(r)$,

$$\frac{1}{\alpha} \frac{\partial T}{\partial t} = \frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{C_1}{r} \right) = 0.$$

Hence, steady-state conditions exist. <

From Equation 2.23, the radial component of the heat flux is

$$q_r'' = -k \frac{\partial T}{\partial r} = -k \frac{C_1}{r}.$$

Hence, q_r'' decreases with increasing r ($q_r'' \propto 1/r$). <

At any radial location, the heat rate is

$$q_r = 2\pi L q_r'' = -2\pi k C_1 L$$

Hence, q_r is independent of r . <

COMMENTS: The requirement that q_r is invariant with r is consistent with the energy conservation requirement. If q_r is constant, the flux must vary inversely with the area perpendicular to the direction of heat flow. Hence, q_r'' varies inversely with r .

PROBLEM 2.38

KNOWN: Inner and outer radii and surface temperatures of a long circular tube with internal energy generation.

FIND: Conditions for which a linear radial temperature distribution may be maintained.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: For the assumed conditions, Eq. 2.24 reduces to

$$\frac{k}{r} \frac{d}{dr} \left(r \frac{dT}{dr} \right) + \dot{q} = 0$$

If $\dot{q} = 0$ or $\dot{q} = \text{constant}$, it is clearly impossible to have a linear radial temperature distribution.

However, we may use the heat equation to infer a special form of $\dot{q}(r)$ for which dT/dr is a constant (call it C_1). It follows that

$$\begin{aligned} \frac{k}{r} \frac{d}{dr} (r C_1) + \dot{q} &= 0 \\ \dot{q} &= -\frac{C_1 k}{r} \end{aligned}$$

<

where $C_1 = (T_2 - T_1)/(r_2 - r_1)$. Hence, if the generation rate varies inversely with radial location, the radial temperature distribution is linear.

COMMENTS: Conditions for which $\dot{q} \propto (1/r)$ would be unusual.

PROBLEM 2.39

KNOWN: Radii and thermal conductivity of conducting rod and cladding material. Volumetric rate of thermal energy generation in the rod. Convection conditions at outer surface.

FIND: Heat equations and boundary conditions for rod and cladding.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r , (3) Constant properties.

ANALYSIS: From Equation 2.24, the appropriate forms of the heat equation are

Conducting Rod:

$$\frac{k_r}{r} \frac{d}{dr} \left(r \frac{dT_r}{dr} \right) + \dot{q} = 0 \quad <$$

Cladding:

$$\frac{d}{dr} \left(r \frac{dT_c}{dr} \right) = 0. \quad <$$

Appropriate boundary conditions are:

$$(a) \quad \left. \frac{dT_r}{dr} \right|_{r=0} = 0 \quad <$$

$$(b) \quad T_r(r_i) = T_c(r_i) \quad <$$

$$(c) \quad k_r \left. \frac{dT_r}{dr} \right|_{r_i} = k_c \left. \frac{dT_c}{dr} \right|_{r_i} \quad <$$

$$(d) \quad -k_c \left. \frac{dT_c}{dr} \right|_{r_o} = h [T_c(r_o) - T_\infty] \quad <$$

COMMENTS: Condition (a) corresponds to symmetry at the centerline, while the interface conditions at $r = r_i$ (b,c) correspond to requirements of thermal equilibrium and conservation of energy. Condition (d) results from conservation of energy at the outer surface. Note that contact resistance at the interface between the rod and cladding has been neglected.

PROBLEM 2.40

KNOWN: Steady-state temperature distribution for hollow cylindrical solid with volumetric heat generation.

FIND: (a) Determine the inner radius of the cylinder, r_i , (b) Obtain an expression for the volumetric rate of heat generation, \dot{q} , (c) Determine the axial distribution of the heat flux at the outer surface, $q_r''(r_o, z)$, and the heat rate at this outer surface; is the heat rate *in* or *out* of the cylinder; (d) Determine the radial distribution of the heat flux at the end faces of the cylinder, $q_z''(r, +z_o)$ and $q_z''(r, -z_o)$, and the corresponding heat rates; are the heat rates *in* or *out* of the cylinder; (e) Determine the relationship of the surface heat rates to the heat generation rate; is an overall energy balance satisfied?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction with constant properties and volumetric heat generation.

ANALYSIS: (a) Since the inner boundary, $r = r_i$, is adiabatic, then $q_r''(r_i, z) = 0$. Hence the temperature gradient in the r -direction must be zero.

$$\left. \frac{\partial T}{\partial r} \right|_{r_i} = 0 + 2br_i + c/r_i + 0 = 0$$

$$r_i = + \left(-\frac{c}{2b} \right)^{1/2} = \left(-\frac{-12^\circ\text{C}}{2 \times 150^\circ\text{C}/\text{m}^2} \right)^{1/2} = 0.2 \text{ m} \quad <$$

(b) To determine \dot{q} , substitute the temperature distribution into the heat diffusion equation, Eq. 2.24, for two-dimensional (r, z) , steady-state conduction

$$\frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial T}{\partial r} \right) + \frac{\partial}{\partial z} \left(\frac{\partial T}{\partial z} \right) + \frac{\dot{q}}{k} = 0$$

$$\frac{1}{r} \frac{\partial}{\partial r} \left(r [0 + 2br + c/r + 0] \right) + \frac{\partial}{\partial z} (0 + 0 + 0 + 2dz) + \frac{\dot{q}}{k} = 0$$

$$\frac{1}{r} [4br + 0] + 2d + \frac{\dot{q}}{k} = 0$$

$$\dot{q} = -k [4b + 2d] = -16 \text{ W/m} \cdot \text{K} \left[4 \times 150^\circ\text{C}/\text{m}^2 + 2(-300^\circ\text{C}/\text{m}^2) \right] = 0 \text{ W}/\text{m}^3 \quad <$$

(c) The heat flux and the heat rate at the outer surface, $r = r_o$, may be calculated using Fourier's law.

$$q_r''(r_o, z) = -k \left. \frac{\partial T}{\partial r} \right|_{r_o} = -k [0 + 2br_o + c/r_o + 0]$$

Continued

PROBLEM 2.40 (Cont.)

$$q_r''(r_o, z) = -16 \text{ W/m} \cdot \text{K} \left[2 \times 150^\circ\text{C/m}^2 \times 1 \text{ m} - 12^\circ\text{C/1 m} \right] = -4608 \text{ W/m}^2 \quad <$$

$$q_r(r_o) = A_r q_r''(r_o, z) \quad \text{where} \quad A_r = 2\pi r_o (2z_o)$$

$$q_r(r_o) = -4\pi \times 1 \text{ m} \times 2.5 \text{ m} \times 4608 \text{ W/m}^2 = -144,765 \text{ W} \quad <$$

Note that the sign of the heat flux and heat rate in the positive r -direction is negative, and hence the heat flow is *into* the cylinder.

(d) The heat fluxes and the heat rates at end faces, $z = +z_o$ and $-z_o$, may be calculated using Fourier's law. The direction of the heat rate *in* or *out* of the end face is determined by the sign of the heat flux in the positive z -direction.

At the upper end face, $z = +z_o$: <

$$q_z''(r, +z_o) = -k \left. \frac{\partial T}{\partial z} \right|_{z_o} = -k [0 + 0 + 0 + 2dz_o]$$

$$q_z''(r, +z_o) = -16 \text{ W/m} \cdot \text{K} \times 2 \left(-300^\circ\text{C/m}^2 \right) 2.5 \text{ m} = +24,000 \text{ W/m}^2 \quad <$$

$$q_z(+z_o) = A_z q_z''(r, +z_o) \quad \text{where} \quad A_z = \pi (r_o^2 - r_i^2)$$

$$q_z(+z_o) = \pi (1^2 - 0.2^2) \text{ m}^2 \times 24,000 \text{ W/m}^2 = +72,382 \text{ W} \quad <$$

Thus, heat flows out of the cylinder.

At the lower end face, $z = -z_o$: <

$$q_z''(r, -z_o) = -k \left. \frac{\partial T}{\partial z} \right|_{-z_o} = -k [0 + 0 + 0 + 2d(-z_o)]$$

$$q_z''(r, -z_o) = -16 \text{ W/m}^2 \cdot \text{K} \times 2 (-300^\circ\text{C/m}) (-2.5 \text{ m}) = -24,000 \text{ W/m}^2 \quad <$$

$$q_z(-z_o) = -72,382 \text{ W} \quad <$$

Again, heat flows out of the cylinder.

(e) The heat rates from the surfaces and the volumetric heat generation can be related through an overall energy balance on the cylinder as shown in the sketch.

Continued...

PROBLEM 2-40 (Conti.)

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = 0 \quad \text{where} \quad \dot{E}_{\text{gen}} = \dot{q} \forall = 0$$

$$\dot{E}_{\text{in}} = -q_r (r_o) = -(-144,765 \text{ W}) = +144,765 \text{ W} \quad <$$

$$\dot{E}_{\text{out}} = +q_z (z_o) - q_z (-z_o) = [72,382 - (-72,382)] \text{ W} = +144,764 \text{ W} \quad <$$

The overall energy balance is satisfied.

COMMENTS: When using Fourier's law, the heat flux q_z'' denotes the heat flux in the positive z -direction. At a boundary, the sign of the numerical value will determine whether heat is flowing into or out of the boundary.

PROBLEM 2.42

KNOWN: Temperature distribution in a spherical shell.

FIND: Whether conditions are steady-state or transient. Manner in which heat flux and heat rate vary with radius.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in r , (2) Constant properties.

ANALYSIS: From Equation 2.27, the heat equation reduces to

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial T}{\partial r} \right) = \frac{1}{\alpha} \frac{\partial T}{\partial t}.$$

Substituting for $T(r)$,

$$\frac{1}{\alpha} \frac{\partial T}{\partial t} = -\frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{C_1}{r^2} \right) = 0.$$

Hence, steady-state conditions exist. <

From Equation 2.26, the radial component of the heat flux is

$$q_r'' = -k \frac{\partial T}{\partial r} = k \frac{C_1}{r^2}.$$

Hence, q_r'' decreases with increasing r^2 ($q_r'' \propto 1/r^2$). <

At any radial location, the heat rate is

$$q_r = 4\pi r^2 q_r'' = 4\pi k C_1.$$

Hence, q_r is independent of r . <

COMMENTS: The fact that q_r is independent of r is consistent with the energy conservation requirement. If q_r is constant, the flux must vary inversely with the area perpendicular to the direction of heat flow. Hence, q_r'' varies inversely with r^2 .

PROBLEM 2.43

KNOWN: Spherical container with an exothermic reaction enclosed by an insulating material whose outer surface experiences convection with adjoining air and radiation exchange with large surroundings.

FIND: (a) Verify that the prescribed temperature distribution for the insulation satisfies the appropriate form of the heat diffusion equation; sketch the temperature distribution and label key features; (b) Applying Fourier's law, verify the conduction heat rate expression for the insulation layer, q_r , in terms of $T_{s,1}$ and $T_{s,2}$; apply a surface energy balance to the container and obtain an alternative expression for q_r in terms of \dot{q} and r_1 ; (c) Apply a surface energy balance around the outer surface of the insulation to obtain an expression to evaluate $T_{s,2}$; (d) Determine $T_{s,2}$ for the specified geometry and operating conditions; (e) Compute and plot the variation of $T_{s,2}$ as a function of the outer radius for the range $201 \leq r_2 \leq 210$ mm; explore approaches for reducing $T_{s,2} \leq 45^\circ\text{C}$ to eliminate potential risk for burn injuries to personnel.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial spherical conduction, (2) Isothermal reaction in container so that $T_o = T_{s,1}$, (2) Negligible thermal contact resistance between the container and insulation, (3) Constant properties in the insulation, (4) Surroundings large compared to the insulated vessel, and (5) Steady-state conditions.

ANALYSIS: The appropriate form of the heat diffusion equation (HDE) for the insulation follows from Eq. 2.27,

$$\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{dT}{dr} \right) = 0 \quad (1) <$$

The temperature distribution is given as

$$T(r) = T_{s,1} - (T_{s,1} - T_{s,2}) \left[\frac{1 - (r_1/r)}{1 - (r_1/r_2)} \right] \quad (2)$$

Substitute $T(r)$ into the HDE to see if it is satisfied:

$$\frac{1}{r^2} \frac{d}{dr} \left(r^2 \left[0 - (T_{s,1} - T_{s,2}) \frac{0 + (r_1/r^2)}{1 - (r_1/r_2)} \right] \right) = 0$$

$$\frac{1}{r^2} \frac{d}{dr} \left(+ (T_{s,1} - T_{s,2}) \frac{r_1}{1 - (r_1/r_2)} \right) = 0 \quad <$$

and since the expression in parenthesis is independent of r , $T(r)$ does indeed satisfy the HDE. The temperature distribution in the insulation and its key features are as follows:

Continued...

PROBLEM 2.43 (Cont.)

(1) $T_{s,1} > T_{s,2}$

- (2) Decreasing gradient with increasing radius, r , since the heat rate is constant through the insulation.

(b) Using Fourier's law for the radial-spherical coordinate, the heat rate through the insulation is

$$q_r = -kA_r \frac{dT}{dr} = -k(4\pi r^2) \frac{dT}{dr}$$

<

and substituting for the temperature distribution, Eq. (2),

$$q_r = -4k\pi r^2 \left[0 - (T_{s,1} - T_{s,2}) \frac{0 + (r_1/r^2)}{1 - (r_1/r_2)} \right]$$

$$q_r = \frac{4\pi k(T_{s,1} - T_{s,2})}{(1/r_1) - (1/r_2)}$$

(3) <

Applying an energy balance to a control surface about the container at $r = r_1$,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\dot{q}\forall - q_r = 0$$

where $\dot{q}\forall$ represents the generated heat in the container,

$$q_r = (4/3)\pi r_1^3 \dot{q}$$

(4) <

(c) Applying an energy balance to a control surface placed around the outer surface of the insulation,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_r - q_{conv} - q_{rad} = 0$$

$$q_r - hA_s(T_{s,2} - T_{\infty}) - \varepsilon A_s \sigma (T_{s,2}^4 - T_{sur}^4) = 0$$

(5) <

Continued...

PROBLEM 2.43 (Cont.)

where

$$A_s = 4\pi r_2^2 \quad (6)$$

These relations can be used to determine $T_{s,2}$ in terms of the variables \dot{q} , r_1 , r_2 , h , T_∞ , ε and T_{sur} .

(d) Consider the reactor system operating under the following conditions:

$$\begin{array}{lll} r_1 = 200 \text{ mm} & h = 5 \text{ W/m}^2\cdot\text{K} & \varepsilon = 0.9 \\ r_2 = 208 \text{ mm} & T_\infty = 25^\circ\text{C} & T_{\text{sur}} = 35^\circ\text{C} \\ k = 0.05 \text{ W/m}\cdot\text{K} & & \end{array}$$

The heat generated by the exothermic reaction provides for a volumetric heat generation rate,

$$\dot{q} = \dot{q}_0 \exp(-A/T_o) \quad \dot{q}_0 = 5000 \text{ W/m}^3 \quad A = 75 \text{ K} \quad (7)$$

where the temperature of the reaction is that of the inner surface of the insulation, $T_o = T_{s,1}$. The following system of equations will determine the operating conditions for the reactor.

Conduction rate equation, insulation, Eq. (3),

$$q_r = \frac{4\pi \times 0.05 \text{ W/m}\cdot\text{K} (T_{s,1} - T_{s,2})}{(1/0.200 \text{ m} - 1/0.208 \text{ m})} \quad (8)$$

Heat generated in the reactor, Eqs. (4) and (7),

$$q_r = 4/3 \pi (0.200 \text{ m})^3 \dot{q} \quad (9)$$

$$\dot{q} = 5000 \text{ W/m}^3 \exp(-75 \text{ K}/T_{s,1}) \quad (10)$$

Surface energy balance, insulation, Eqs. (5) and (6),

$$q_r - 5 \text{ W/m}^2 \cdot \text{K} A_s (T_{s,2} - 298 \text{ K}) - 0.9 A_s 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 (T_{s,2}^4 - (308 \text{ K})^4) = 0 \quad (11)$$

$$A_s = 4\pi (0.208 \text{ m})^2 \quad (12)$$

Solving these equations simultaneously, find that

$$T_{s,1} = 94.3^\circ\text{C} \quad T_{s,2} = 52.5^\circ\text{C} \quad <$$

That is, the reactor will be operating at $T_o = T_{s,1} = 94.3^\circ\text{C}$, very close to the desired 95°C operating condition.

(e) Using the above system of equations, Eqs. (8)-(12), we have explored the effects of changes in the convection coefficient, h , and the insulation thermal conductivity, k , as a function of insulation thickness, $t = r_2 - r_1$.

Continued...

PROBLEM 2.43 (Cont.)

In the $T_{s,2}$ vs. $(r_2 - r_1)$ plot, note that decreasing the thermal conductivity from 0.05 to 0.01 W/m·K slightly increases $T_{s,2}$ while increasing the convection coefficient from 5 to 15 W/m²·K markedly decreases $T_{s,2}$. Insulation thickness only has a minor effect on $T_{s,2}$ for either option. In the T_o vs. $(r_2 - r_1)$ plot, note that, for all the options, the effect of increased insulation is to increase the reaction temperature. With $k = 0.01$ W/m·K, the reaction temperature increases beyond 95°C with less than 2 mm insulation. For the case with $h = 15$ W/m²·K, the reaction temperature begins to approach 95°C with insulation thickness around 10 mm. We conclude that by selecting the proper insulation thickness and controlling the convection coefficient, the reaction could be operated around 95°C such that the outer surface temperature would not exceed 45°C.

PROBLEM 2.44

KNOWN: One-dimensional system, initially at a uniform temperature T_i , is suddenly exposed to a uniform heat flux at one boundary, while the other boundary is insulated.

FIND: (a) Proper form of heat equation and boundary and initial conditions, (b) Temperature distributions for following conditions: initial condition ($t \leq 0$), and several times after heater is energized; will a steady-state condition be reached; (c) Heat flux at $x = 0, L/2, L$ as a function of time; (d) Expression for uniform temperature, T_f , reached after heater has been switched off following an elapsed time, t_e , with the heater on.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) No internal heat generation, (3) Constant properties.

ANALYSIS: (a) The appropriate form of the heat equation follows from Eq. 2.19. Also, the appropriate boundary and initial conditions are:

Initial condition: $T(x, 0) = T_i$ Uniform temperature

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

Boundary conditions: $x = 0 \quad q''_0 = -k \partial T / \partial x|_0$

$x = L \quad \partial T / \partial x|_L = 0$

(b) The temperature distributions are as follows:

No steady-state condition will be reached since $\dot{E}_{in} = \dot{E}_{st}$ and \dot{E}_{in} is constant.

(c) The heat flux as a function of time for positions $x = 0, L/2$ and L is as follows:

(d) If the heater is energized until $t = t_e$ and then switched off, the system will eventually reach a uniform temperature, T_f . Perform an energy balance on the system, Eq. 1.11b, for an interval of time $\Delta t = t_e$,

$$E_{in} = E_{st} \quad E_{in} = Q_{in} = \int_0^{t_e} q''_0 A_s dt = q''_0 A_s t_e \quad E_{st} = Mc(T_f - T_i)$$

It follows that $q''_0 A_s t_e = Mc(T_f - T_i)$ or $T_f = T_i + \frac{q''_0 A_s t_e}{Mc}$.

PROBLEM 2.45

KNOWN: Plate of thickness $2L$, initially at a uniform temperature of $T_i = 200^\circ\text{C}$, is suddenly quenched in a liquid bath of $T_\infty = 20^\circ\text{C}$ with a convection coefficient of $100 \text{ W/m}^2\cdot\text{K}$.

FIND: (a) On T - x coordinates, sketch the temperature distributions for the initial condition ($t \leq 0$), the steady-state condition ($t \rightarrow \infty$), and two intermediate times; (b) On q_x'' - t coordinates, sketch the variation with time of the heat flux at $x = L$, (c) Determine the heat flux at $x = L$ and for $t = 0$; what is the temperature gradient for this condition; (d) By performing an energy balance on the plate, determine the amount of energy per unit surface area of the plate (J/m^2) that is transferred to the bath over the time required to reach steady-state conditions; and (e) Determine the energy transferred to the bath during the quenching process using the exponential-decay relation for the surface heat flux.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, and (3) No internal heat generation.

ANALYSIS: (a) The temperature distributions are shown in the sketch below.

(b) The heat flux at the surface $x = L$, $q_x''(L, t)$, is initially a maximum value, and decreases with increasing time as shown in the sketch above.

(c) The heat flux at the surface $x = L$ at time $t = 0$, $q_x''(L, 0)$, is equal to the convection heat flux with the surface temperature as $T(L, 0) = T_i$.

$$q_x''(L, 0) = q_{\text{conv}}''(t = 0) = h(T_i - T_\infty) = 100 \text{ W/m}^2\cdot\text{K} (200 - 20)^\circ\text{C} = 18.0 \text{ kW/m}^2 <$$

From a surface energy balance as shown in the sketch considering the conduction and convection fluxes at the surface, the temperature gradient can be calculated.

Continued

PROBLEM 2.45 (Cont.)

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$q_x''(L, 0) - q_{\text{conv}}''(t = 0) = 0 \quad \text{with} \quad q_x''(L, 0) = -k \left. \frac{\partial T}{\partial x} \right|_{x=L}$$

$$\left. \frac{\partial T}{\partial x} \right|_{L,0} = -q_{\text{conv}}''(t = 0) / k = -18 \times 10^3 \text{ W/m}^2 / 50 \text{ W/m} \cdot \text{K} = -360 \text{ K/m} \quad <$$

(d) The energy transferred from the plate to the bath over the time required to reach steady-state conditions can be determined from an energy balance on a time interval basis, Eq. 1.11b. For the initial state, the plate has a uniform temperature T_i ; for the final state, the plate is at the temperature of the bath, T_∞ .

$$E_{\text{in}}'' - E_{\text{out}}'' = \Delta E_{\text{st}}'' = E_f'' - E_i'' \quad \text{with} \quad E_{\text{in}}'' = 0,$$

$$-E_{\text{out}}'' = \rho c_p (2L) [T_\infty - T_i]$$

$$E_{\text{out}}'' = -2770 \text{ kg/m}^3 \times 875 \text{ J/kg} \cdot \text{K} (2 \times 0.010 \text{ m}) [20 - 200] \text{ K} = +8.73 \times 10^6 \text{ J/m}^2 \quad <$$

(e) The energy transfer from the plate to the bath during the quenching process can be evaluated from knowledge of the surface heat flux as a function of time. The area under the curve in the $q_x''(L, t)$ vs. time plot (see schematic above) represents the energy transferred during the quench process.

$$E_{\text{out}}'' = 2 \int_{t=0}^{\infty} q_x''(L, t) dt = 2 \int_{t=0}^{\infty} A e^{-Bt} dt$$

$$E_{\text{out}}'' = 2A \left[-\frac{1}{B} e^{-Bt} \right]_0^{\infty} = 2A \left[-\frac{1}{B} (0 - 1) \right] = 2A / B$$

$$E_{\text{out}}'' = 2 \times 1.80 \times 10^4 \text{ W/m}^2 / 4.126 \times 10^{-3} \text{ s}^{-1} = 8.73 \times 10^6 \text{ J/m}^2 \quad <$$

COMMENTS: (1) Can you identify and explain the important features in the temperature distributions of part (a)?

(2) The maximum heat flux from the plate occurs at the instant the quench process begins and is equal to the convection heat flux. At this instant, the gradient in the plate at the surface is a maximum. If the gradient is too large, excessive thermal stresses could be induced and cracking could occur.

(3) In this thermodynamic analysis, we were able to determine the energy transferred during the quenching process. We cannot determine the rate at which cooling of the plate occurs without solving the heat diffusion equation.

PROBLEM 2.46

KNOWN: Plane wall, initially at a uniform temperature, is suddenly exposed to convective heating.

FIND: (a) Differential equation and initial and boundary conditions which may be used to find the temperature distribution, $T(x,t)$; (b) Sketch $T(x,t)$ for these conditions: initial ($t \leq 0$), steady-state, $t \rightarrow \infty$, and two intermediate times; (c) Sketch heat fluxes as a function of time for surface locations; (d) Expression for total energy transferred to wall per unit volume (J/m^3).

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal heat generation.

ANALYSIS: (a) For one-dimensional conduction with constant properties, the heat equation has the form,

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

and the conditions are:

$$\begin{cases} \text{Initial, } t \leq 0: & T(x,0) = T_i \\ \text{Boundaries: } & x=0 \quad \partial T / \partial x|_0 = 0 \\ & x=L \quad -k \partial T / \partial x|_L = h [T(L,t) - T_\infty] \end{cases} \quad \begin{array}{l} \text{uniform} \\ \text{adiabatic} \\ \text{convection} \end{array}$$

(b) The temperature distributions are shown on the sketch.

Note that the gradient at $x = 0$ is always zero, since this boundary is adiabatic. Note also that the gradient at $x = L$ decreases with time.

(c) The heat flux, $q_x''(x,t)$, as a function of time, is shown on the sketch for the surfaces $x = 0$ and $x = L$.

Continued

PROBLEM 2.46 (Cont.)

For the surface at $x = 0$, $q''_x(0, t) = 0$ since it is adiabatic. At $x = L$ and $t = 0$, $q''_x(L, 0)$ is a maximum (in magnitude)

$$|q''_x(L, 0)| = h |T(L, 0) - T_\infty|$$

where $T(L, 0) = T_i$. The temperature difference, and hence the flux, decreases with time.

(d) The total energy transferred to the wall may be expressed as

$$E_{in} = \int_0^\infty q''_{conv} A_s dt$$

$$E_{in} = h A_s \int_0^\infty (T_\infty - T(L, t)) dt$$

Dividing both sides by $A_s L$, the energy transferred per unit volume is

$$\frac{E_{in}}{V} = \frac{h}{L} \int_0^\infty [T_\infty - T(L, t)] dt \quad \left[\text{J/m}^3 \right]$$

COMMENTS: Note that the heat flux at $x = L$ is into the wall and is hence in the negative x direction.

PROBLEM 2.47

KNOWN: Plane wall, initially at a uniform temperature T_i , is suddenly exposed to convection with a fluid at T_∞ at one surface, while the other surface is exposed to a constant heat flux q_o'' .

FIND: (a) Temperature distributions, $T(x,t)$, for initial, steady-state and two intermediate times, (b) Corresponding heat fluxes on $q_x'' - x$ coordinates, (c) Heat flux at locations $x = 0$ and $x = L$ as a function of time, (d) Expression for the steady-state temperature of the heater, $T(0,\infty)$, in terms of q_o'' , T_∞ , k , h and L .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) No heat generation, (3) Constant properties.

ANALYSIS: (a) For $T_i < T_\infty$, the temperature distributions are

Note the constant gradient at $x = 0$ since $q_x''(0) = q_o''$.

(b) The heat flux distribution, $q_x''(x,t)$, is determined from knowledge of the temperature gradients, evident from Part (a), and Fourier's law.

(c) On $q_x''(x,t) - t$ coordinates, the heat fluxes at the boundaries are shown above.

(d) Perform a surface energy balance at $x = L$ and an energy balance on the wall:

$$q_{\text{cond}}'' = q_{\text{conv}}'' = h[T(L,\infty) - T_\infty] \quad (1), \quad q_{\text{cond}}'' = q_o'' \quad (2)$$

For the wall, under steady-state conditions, Fourier's law gives

$$q_o'' = -k \frac{dT}{dx} = k \frac{T(0,\infty) - T(L,\infty)}{L} \quad (3)$$

Combine Eqs. (1), (2), (3) to find:

$$T(0,\infty) = T_\infty + \frac{q_o''}{1/h + L/k}$$

PROBLEM 2.48

KNOWN: Plane wall, initially at a uniform temperature T_0 , has one surface ($x = L$) suddenly exposed to a convection process ($T_\infty > T_0, h$), while the other surface ($x = 0$) is maintained at T_0 . Also, wall experiences uniform volumetric heating \dot{q} such that the maximum steady-state temperature will exceed T_∞ .

FIND: (a) Sketch temperature distribution (T vs. x) for following conditions: initial ($t \leq 0$), steady-state ($t \rightarrow \infty$), and two intermediate times; also show distribution when there is no heat flow at the $x = L$ boundary, (b) Sketch the heat flux (q_x'' vs. t) at the boundaries $x = 0$ and L .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Uniform volumetric generation, (4) $T_0 < T_\infty$ and \dot{q} large enough that $T(x, \infty) > T_\infty$ for some x .

ANALYSIS: (a) The initial and boundary conditions for the wall can be written as

<i>Initial</i> ($t \leq 0$):	$T(x, 0) = T_0$	Uniform temperature
<i>Boundary:</i>	$x = 0 \quad T(0, t) = T_0$	Constant temperature
	$x = L \quad -k \frac{\partial T}{\partial x} \bigg _{x=L} = h [T(L, t) - T_\infty]$	Convection process.

The temperature distributions are shown on the T - x coordinates below. Note the special condition when the heat flux at ($x = L$) is zero.

(b) The heat flux as a function of time at the boundaries, $q_x''(0, t)$ and $q_x''(L, t)$, can be inferred from the temperature distributions using Fourier's law.

COMMENTS: Since $T(x, \infty) > T_\infty$ for some x and $T_\infty > T_0$, heat transfer at both boundaries must be out of the wall at steady state. From an overall energy balance at steady state, $+q_x''(L, \infty) - q_x''(0, \infty) = \dot{q}L$.

PROBLEM 2.49

KNOWN: Plane wall, initially at a uniform temperature T_o , has one surface ($x = L$) suddenly exposed to a convection process ($T_\infty < T_o$, h), while the other surface ($x = 0$) is maintained at T_o . Also, wall experiences uniform volumetric heating \dot{q} such that the maximum steady-state temperature will exceed T_∞ .

FIND: (a) Sketch temperature distribution (T vs. x) for following conditions: initial ($t \leq 0$), steady-state ($t \rightarrow \infty$), and two intermediate times; identify key features of the distributions, (b) Sketch the heat flux (q''_x vs. t) at the boundaries $x = 0$ and L ; identify key features of the distributions.

SCHEMATIC:

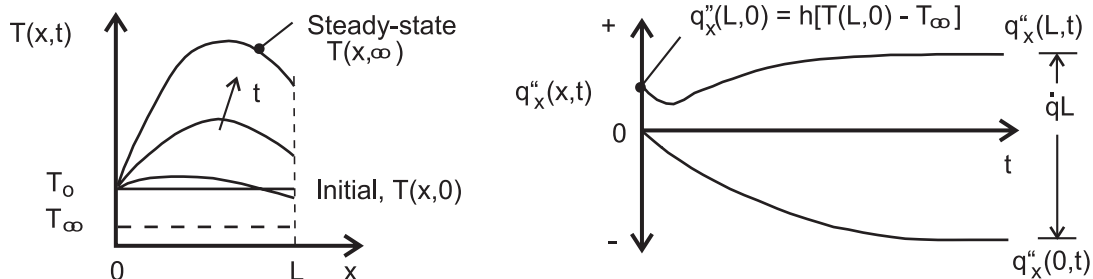

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Uniform volumetric generation, (4) $T_\infty < T_o$ and \dot{q} large enough that $T(x, \infty) > T_o$.

ANALYSIS: (a) The initial and boundary conditions for the wall can be written as

<i>Initial</i> ($t \leq 0$):	$T(x, 0) = T_o$	Uniform temperature
<i>Boundary:</i>	$x = 0 \quad T(0, t) = T_o$	Constant temperature
	$x = L \quad -k \frac{\partial T}{\partial x} \bigg _{x=L} = h [T(L, t) - T_\infty]$	Convection process.

The temperature distributions are shown on the T - x coordinates below. Note that the maximum temperature occurs under steady-state conditions not at the midplane, but to the right toward the surface experiencing convection. The temperature gradients at $x = L$ increase for $t > 0$ since the convection heat rate from the surface increases as the surface temperature increases.

(b) The heat flux as a function of time at the boundaries, $q''_x(0, t)$ and $q''_x(L, t)$, can be inferred from the temperature distributions using Fourier's law. At the surface $x = L$, the convection heat flux at $t = 0$ is $q''_x(L, 0) = h(T_o - T_\infty)$. Because the surface temperature dips slightly at early times, the convection heat flux decreases slightly, and then increases until the steady-state condition is reached. For the steady-state condition, heat transfer at both boundaries must be out of the wall. It follows from an overall energy balance on the wall that $+q''_x(0, \infty) - q''_x(L, \infty) + \dot{q}L = 0$.

PROBLEM 2.50

KNOWN: Size and thermal conductivities of a spherical particle encased by a spherical shell.

FIND: (a) Relationship between dT/dr and r for $0 \leq r \leq r_1$, (b) Relationship between dT/dr and r for $r_1 \leq r \leq r_2$, (c) Sketch of $T(r)$ over the range $0 \leq r \leq r_2$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer.

ANALYSIS:

(a) The conservation of energy principle, applied to control volume A, results in

$$\dot{E}_{\text{in}} + \dot{E}_g - \dot{E}_{\text{out}} = \dot{E}_{\text{st}} \quad (1)$$

where $\dot{E}_g = \dot{q}V = \dot{q} \frac{4}{3} \pi r^3$ (2)

since $\dot{E}_{\text{st}} = 0$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = q_r'' A = - (k_1 \frac{dT}{dr})(4\pi r^2) \quad (3)$$

Substituting Eqs. (2) and (3) in Eq. (1) yields

$$\dot{q} \frac{4}{3} \pi r^3 + k_1 \frac{dT}{dr} (4\pi r^2) = 0$$

or

$$\frac{dT}{dr} = - \frac{\dot{q}}{3 k_1} r$$

<

Continued...

PROBLEM 2.50 (Cont.)

(b) For $r > r_1$, the radial heat rate is constant and is

$$\dot{E}_g = \dot{q}_r = \dot{q} \forall_1 = \dot{q} \frac{4}{3} \pi r_1^3 \quad (4)$$

$$\dot{E}_{in} - \dot{E}_{out} = \dot{q}_r'' A = - \left(k_2 \frac{dT}{dr} \right) 4\pi r^2 \quad (5)$$

Substituting Eqs. (4) and (5) into Eq. (1) yields

$$k_2 \frac{dT}{dr} 4\pi r^2 + \dot{q} \frac{4}{3} \pi r_1^3$$

or

$$\frac{dT}{dr} = - \frac{\dot{q} r_1^3}{3k_2 r^2} \quad <$$

(c) The temperature distribution on T-r coordinates is

COMMENTS: (1) Note the non-linear temperature distributions in both the particle and the shell. (2) The temperature gradient at $r = 0$ is zero. (3) The discontinuous slope of $T(r)$ at $r_1/r_2 = 0.5$ is a result of $k_1 = 2k_2$.

PROBLEM 2.51

KNOWN: Temperature distribution in a plane wall of thickness L experiencing uniform volumetric heating \dot{q} having one surface ($x = 0$) insulated and the other exposed to a convection process characterized by T_∞ and h . Suddenly the volumetric heat generation is deactivated while convection continues to occur.

FIND: (a) Determine the magnitude of the volumetric energy generation rate associated with the initial condition, (b) On T - x coordinates, sketch the temperature distributions for the initial condition ($T \leq 0$), the steady-state condition ($t \rightarrow \infty$), and two intermediate times; (c) On q_x'' - t coordinates, sketch the variation with time of the heat flux at the boundary exposed to the convection process, $q_x''(L, t)$; calculate the corresponding value of the heat flux at $t = 0$; and (d) Determine the amount of energy removed from the wall per unit area (J/m^2) by the fluid stream as the wall cools from its initial to steady-state condition.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, and (3) Uniform internal volumetric heat generation for $t < 0$.

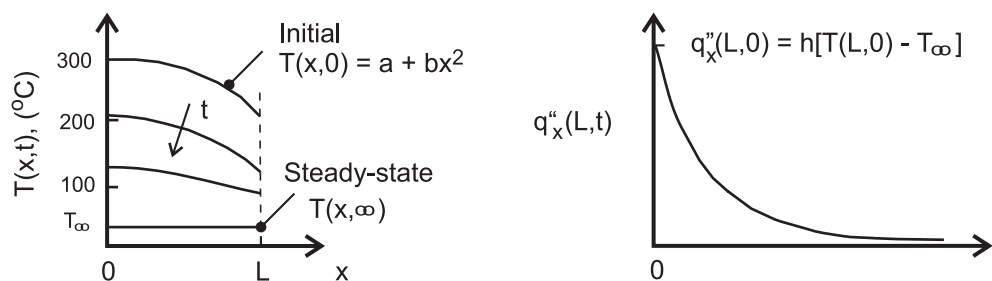

ANALYSIS: (a) The volumetric heating rate can be determined by substituting the temperature distribution for the initial condition into the appropriate form of the heat diffusion equation.

$$\frac{d}{dx} \left(\frac{dT}{dx} \right) + \frac{\dot{q}}{k} = 0 \quad \text{where} \quad T(x, 0) = a + bx^2$$

$$\frac{d}{dx} (0 + 2bx) + \frac{\dot{q}}{k} = 0 = 2b + \frac{\dot{q}}{k} = 0$$

$$\dot{q} = -2kb = -2 \times 90 \text{ W/m}\cdot\text{K} \left(-1.0 \times 10^4 \text{ }^\circ\text{C/m}^2 \right) = 1.8 \times 10^6 \text{ W/m}^3 \quad <$$

(b) The temperature distributions are shown in the sketch below.

Continued

PROBLEM 2.51 (Cont.)

(c) The heat flux at the exposed surface $x = L$, $q_x''(L, 0)$, is initially a maximum value and decreases with increasing time as shown in the sketch above. The heat flux at $t = 0$ is equal to the convection heat flux with the surface temperature $T(L, 0)$. See the surface energy balance represented in the schematic.

$$q_x''(L, 0) = q_{\text{conv}}''(t = 0) = h(T(L, 0) - T_\infty) = 1000 \text{ W/m}^2 \cdot \text{K} (200 - 20)^\circ\text{C} = 1.80 \times 10^5 \text{ W/m}^2 <$$

$$\text{where } T(L, 0) = a + bL^2 = 300^\circ\text{C} - 1.0 \times 10^4^\circ\text{C/m}^2 (0.1\text{m})^2 = 200^\circ\text{C}.$$

(d) The energy removed from the wall to the fluid as it cools from its initial to steady-state condition can be determined from an energy balance on a time interval basis, Eq. 1.11b. For the initial state, the wall has the temperature distribution $T(x, 0) = a + bx^2$; for the final state, the wall is at the temperature of the fluid, $T_f = T_\infty$. We have used T_∞ as the reference condition for the energy terms.

$$E_{\text{in}}'' - E_{\text{out}}'' = \Delta E_{\text{st}}'' = E_f'' - E_i'' \quad \text{with} \quad E_{\text{in}}'' = 0$$

$$E_{\text{out}}'' = \rho c_p \int_{x=0}^{x=L} [T(x, 0) - T_\infty] dx$$

$$E_{\text{out}}'' = \rho c_p \int_{x=0}^{x=L} [a + bx^2 - T_\infty] dx = \rho c_p \left[ax + bx^3/3 - T_\infty x \right]_0^L$$

$$E_{\text{out}}'' = 7000 \text{ kg/m}^3 \times 450 \text{ J/kg} \cdot \text{K} \left[300 \times 0.1 - 1.0 \times 10^4 (0.1)^3 / 3 - 20 \times 0.1 \right] \text{ K} \cdot \text{m}$$

$$E_{\text{out}}'' = 7.77 \times 10^7 \text{ J/m}^2 <$$

COMMENTS: (1) In the temperature distributions of part (a), note these features: initial condition has quadratic form with zero gradient at the adiabatic boundary; for the steady-state condition, the wall has reached the temperature of the fluid; for all distributions, the gradient at the adiabatic boundary is zero; and, the gradient at the exposed boundary decreases with increasing time.

(2) In this thermodynamic analysis, we were able to determine the energy transferred during the cooling process. However, we cannot determine the rate at which cooling of the wall occurs without solving the heat diffusion equation.

PROBLEM 2.52

KNOWN: Temperature as a function of position and time in a plane wall suddenly subjected to a change in surface temperature, while the other surface is insulated.

FIND: (a) Validate the temperature distribution, (b) Heat fluxes at $x = 0$ and $x = L$, (c) Sketch of temperature distribution at selected times and surface heat flux variation with time, (d) Effect of thermal diffusivity on system response.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x , (2) Constant properties.

ANALYSIS: (a) To be valid, the temperature distribution must satisfy the appropriate forms of the heat equation and boundary conditions. Substituting the distribution into Equation 2.19, it follows that

$$\begin{aligned}
 \frac{\partial^2 T}{\partial x^2} &= \frac{1}{\alpha} \frac{\partial T}{\partial t} \\
 -C_1 (T_i - T_s) \exp\left(-\frac{\pi^2}{4} \frac{\alpha t}{L^2}\right) \left(\frac{\pi}{2L}\right)^2 \cos\left(\frac{\pi x}{2L}\right) \\
 &= -\frac{C_1}{\alpha} (T_i - T_s) \left(\frac{\pi^2}{4} \frac{\alpha}{L^2}\right) \exp\left(-\frac{\pi^2}{4} \frac{\alpha t}{L^2}\right) \cos\left(\frac{\pi x}{2L}\right). \quad <
 \end{aligned}$$

Hence, the heat equation is satisfied. Applying boundary conditions at $x = 0$ and $x = L$, it follows that

$$\left. \frac{\partial T}{\partial x} \right|_{x=0} = -\frac{C_1 \pi}{2L} (T_i - T_s) \exp\left(-\frac{\pi^2}{4} \frac{\alpha t}{L^2}\right) \sin\left(\frac{\pi x}{2L}\right) \Big|_{x=0} = 0 \quad <$$

and

$$T(L, t) = T_s + C_1 (T_i - T_s) \exp\left(-\frac{\pi^2}{4} \frac{\alpha t}{L^2}\right) \cos\left(\frac{\pi x}{2L}\right) \Big|_{x=L} = T_s. \quad <$$

Hence, the boundary conditions are also satisfied.

(b) The heat flux has the form

$$q_x'' = -k \frac{\partial T}{\partial x} = +\frac{k C_1 \pi}{2L} (T_i - T_s) \exp\left(-\frac{\pi^2}{4} \frac{\alpha t}{L^2}\right) \sin\left(\frac{\pi x}{2L}\right).$$

Continued

PROBLEM 2.52 (Cont.)

Hence, $q_x''(0) = 0$,

<

$$q_x''(L) = +\frac{kC_1\pi}{2L}(T_i - T_s)\exp\left(-\frac{\pi^2}{4}\frac{\alpha t}{L^2}\right).$$

<

(c) The temperature distribution and surface heat flux variations are:

(d) For materials A and B of different α ,

$$\frac{[T(x,t) - T_s]_A}{[T(x,t) - T_s]_B} = \exp\left[-\frac{\pi^2}{4L^2}(\alpha_A - \alpha_B)t\right]$$

Hence, if $\alpha_A > \alpha_B$, $T(x,t) \rightarrow T_s$ more rapidly for Material A. If $\alpha_A < \alpha_B$, $T(x,t) \rightarrow T_s$ more rapidly for Material B.

<

COMMENTS: Note that the prescribed function for $T(x,t)$ does not reduce to T_i for $t \rightarrow 0$. For times at or close to zero, the function is not a valid solution of the problem. At such times, the solution for $T(x,t)$ must include additional terms. The solution is considered in Section 5.5.1 of the text.

PROBLEM 2.53

KNOWN: Thin electrical heater dissipating 4000 W/m^2 sandwiched between two 25-mm thick plates whose surfaces experience convection.

FIND: (a) On T-x coordinates, sketch the steady-state temperature distribution for $-L \leq x \leq +L$; calculate values for the surfaces $x = L$ and the mid-point, $x = 0$; label this distribution as Case 1 and explain key features; (b) Case 2: sudden loss of coolant causing existence of adiabatic condition on the $x = +L$ surface; sketch temperature distribution on same T-x coordinates as part (a) and calculate values for $x = 0, \pm L$; explain key features; (c) Case 3: further loss of coolant and existence of adiabatic condition on the $x = -L$ surface; situation goes undetected for 15 minutes at which time power to the heater is deactivated; determine the eventual ($t \rightarrow \infty$) uniform, steady-state temperature distribution; sketch temperature distribution on same T-x coordinates as parts (a,b); and (d) On T-t coordinates, sketch the temperature-time history at the plate locations $x = 0, \pm L$ during the transient period between the steady-state distributions for Case 2 and Case 3; at what location and when will the temperature in the system achieve a maximum value?

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal volumetric generation in plates, and (3) Negligible thermal resistance between the heater surfaces and the plates.

ANALYSIS: (a) Since the system is symmetrical, the heater power results in equal conduction fluxes through the plates. By applying a surface energy balance on the surface $x = +L$ as shown in the schematic, determine the temperatures at the mid-point, $x = 0$, and the exposed surface, $x = +L$.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$q''_x(+L) - q''_{\text{conv}} = 0 \quad \text{where} \quad q''_x(+L) = q''_0 / 2$$

$$q''_0 / 2 - h[T(+L) - T_\infty] = 0$$

$$T_1(+L) = q''_0 / 2h + T_\infty = 4000 \text{ W/m}^2 / (2 \times 400 \text{ W/m}^2 \cdot \text{K}) + 20^\circ\text{C} = 25^\circ\text{C} \quad <$$

From Fourier's law for the conduction flux through the plate, find $T(0)$.

$$q''_x = q''_0 / 2 = k[T(0) - T(+L)] / L$$

$$T_1(0) = T_1(+L) + q''_0 L / 2k = 25^\circ\text{C} + 4000 \text{ W/m}^2 \cdot \text{K} \times 0.025 \text{ m} / (2 \times 5 \text{ W/m} \cdot \text{K}) = 35^\circ\text{C} \quad <$$

The temperature distribution is shown on the T-x coordinates below and labeled Case 1. The key features of the distribution are its symmetry about the heater plane and its linear dependence with distance.

Continued

PROBLEM 2.53 (Cont.)

(b) Case 2: sudden loss of coolant with the existence of an adiabatic condition on surface $x = +L$. For this situation, all the heater power will be conducted to the coolant through the left-hand plate. From a surface energy balance and application of Fourier's law as done for part (a), find

$$T_2(-L) = q_0'' / h + T_\infty = 4000 \text{ W/m}^2 / 400 \text{ W/m}^2 \cdot \text{K} + 20^\circ\text{C} = 30^\circ\text{C} \quad <$$

$$T_2(0) = T_2(-L) + q_0'' L / k = 30^\circ\text{C} + 4000 \text{ W/m}^2 \times 0.025 \text{ m} / 5 \text{ W/m} \cdot \text{K} = 50^\circ\text{C} \quad <$$

The temperature distribution is shown on the T - x coordinates above and labeled Case 2. The distribution is linear in the left-hand plate, with the maximum value at the mid-point. Since no heat flows through the right-hand plate, the gradient must be zero and this plate is at the maximum temperature as well. The maximum temperature is higher than for Case 1 because the heat flux through the left-hand plate has increased two-fold.

(c) Case 3: sudden loss of coolant occurs at the $x = -L$ surface also. For this situation, there is no heat transfer out of either plate, so that for a 15-minute period, Δt_0 , the heater dissipates 4000 W/m^2 and then is deactivated. To determine the eventual, uniform steady-state temperature distribution, apply the conservation of energy requirement on a time-interval basis, Eq. 1.11b. The initial condition corresponds to the temperature distribution of Case 2, and the final condition will be a uniform, elevated temperature $T_f = T_3$ representing Case 3. We have used T_∞ as the reference condition for the energy terms.

$$E_{\text{in}}'' - E_{\text{out}}'' + E_{\text{gen}}'' = \Delta E_{\text{st}}'' = E_f'' - E_i'' \quad (1)$$

Note that $E_{\text{in}}'' - E_{\text{out}}'' = 0$, and the dissipated electrical energy is

$$E_{\text{gen}}'' = q_0'' \Delta t_0 = 4000 \text{ W/m}^2 (15 \times 60) \text{ s} = 3.600 \times 10^6 \text{ J/m}^2 \quad (2)$$

For the final condition,

$$\begin{aligned} E_f'' &= \rho c (2L) [T_f - T_\infty] = 2500 \text{ kg/m}^3 \times 700 \text{ J/kg} \cdot \text{K} (2 \times 0.025 \text{ m}) [T_f - 20]^\circ\text{C} \\ E_f'' &= 8.75 \times 10^4 [T_f - 20] \text{ J/m}^2 \end{aligned} \quad (3)$$

where $T_f = T_3$, the final uniform temperature, Case 3. For the initial condition,

$$E_i'' = \rho c \int_{-L}^{+L} [T_2(x) - T_\infty] dx = \rho c \left\{ \int_{-L}^0 [T_2(x) - T_\infty] dx + \int_0^{+L} [T_2(0) - T_\infty] dx \right\} \quad (4)$$

where $T_2(x)$ is linear for $-L \leq x \leq 0$ and constant at $T_2(0)$ for $0 \leq x \leq +L$.

$$\begin{aligned} T_2(x) &= T_2(0) + [T_2(0) - T_2(L)] x / L & -L \leq x \leq 0 \\ T_2(x) &= 50^\circ\text{C} + [50 - 30]^\circ\text{C} x / 0.025 \text{ m} \\ T_2(x) &= 50^\circ\text{C} + 800x \end{aligned} \quad (5)$$

Substituting for $T_2(x)$, Eq. (5), into Eq. (4)

Continued

PROBLEM 2.53 (Cont.)

$$\begin{aligned}
 E_1'' &= \rho c \left\{ \int_{-L}^0 [50 + 800x - T_\infty] dx + [T_2(0) - T_\infty] L \right\} \\
 E_1'' &= \rho c \left\{ \left[50x + 400x^2 - T_\infty x \right]_{-L}^0 + [T_2(0) - T_\infty] L \right\} \\
 E_1'' &= \rho c \left\{ -[-50L + 400L^2 + T_\infty L] + [T_2(0) - T_\infty] L \right\} \\
 E_1'' &= \rho c L \{ +50 - 400L - T_\infty + T_2(0) - T_\infty \} \\
 E_1'' &= 2500 \text{ kg/m}^3 \times 700 \text{ J/kg} \cdot \text{K} \times 0.025 \text{ m} \{ +50 - 400 \times 0.025 - 20 + 50 - 20 \} \text{ K} \\
 E_1'' &= 2.188 \times 10^6 \text{ J/m}^2 \quad (6)
 \end{aligned}$$

Returning to the energy balance, Eq. (1), and substituting Eqs. (2), (3) and (6), find $T_f = T_3$.

$$3.600 \times 10^6 \text{ J/m}^2 = 8.75 \times 10^4 [T_3 - 20] - 2.188 \times 10^6 \text{ J/m}^2$$

$$T_3 = (66.1 + 20)^\circ\text{C} = 86.1^\circ\text{C}$$

<

The temperature distribution is shown on the T-x coordinates above and labeled Case 3. The distribution is uniform, and considerably higher than the maximum value for Case 2.

(d) The temperature-time history at the plate locations $x = 0, \pm L$ during the transient period between the distributions for Case 2 and Case 3 are shown on the T-t coordinates below.

Note the temperatures for the locations at time $t = 0$ corresponding to the instant when the surface $x = -L$ becomes adiabatic. These temperatures correspond to the distribution for Case 2. The heater remains energized for yet another 15 minutes and then is deactivated. The midpoint temperature, $T(0,t)$, is always the hottest location and the maximum value slightly exceeds the final temperature T_3 .

PROBLEM 2.54

KNOWN: Radius and length of coiled wire in hair dryer. Electric power dissipation in the wire, and temperature and convection coefficient associated with air flow over the wire.

FIND: (a) Form of heat equation and conditions governing transient, thermal behavior of wire during start-up, (b) Volumetric rate of thermal energy generation in the wire, (c) Sketch of temperature distribution at selected times during start-up, (d) Variation with time of heat flux at $r = 0$ and $r = r_o$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Constant properties, (3) Uniform volumetric heating, (4) Negligible radiation from surface of wire.

ANALYSIS: (a) The general form of the heat equation for cylindrical coordinates is given by Eq. 2.24. For one-dimensional, radial conduction and constant properties, the equation reduces to

$$\frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial T}{\partial r} \right) + \frac{\dot{q}}{k} = \frac{\rho c_p}{k} \frac{\partial T}{\partial t} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad <$$

The initial condition is $T(r, 0) = T_i$ <

The boundary conditions are: $\partial T / \partial r|_{r=0} = 0$ <

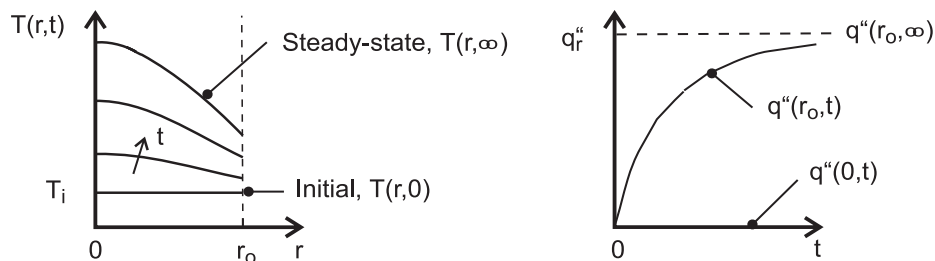

$$-k \frac{\partial T}{\partial r} \bigg|_{r=r_o} = h [T(r_o, t) - T_\infty] \quad <$$

(b) The volumetric rate of thermal energy generation is

$$\dot{q} = \frac{\dot{E}_g}{V} = \frac{P_{\text{elec}}}{\pi r_o^2 L} = \frac{500 \text{ W}}{\pi (0.001 \text{ m})^2 (0.5 \text{ m})} = 3.18 \times 10^8 \text{ W/m}^3 \quad <$$

Under steady-state conditions, all of the thermal energy generated within the wire is transferred to the air by convection. Performing an energy balance for a control surface about the wire, $-\dot{E}_{\text{out}} + \dot{E}_g = 0$, it follows that $-2\pi r_o L q''(r_o, t \rightarrow \infty) + P_{\text{elec}} = 0$. Hence,

$$q''(r_o, t \rightarrow \infty) = \frac{P_{\text{elec}}}{2\pi r_o L} = \frac{500 \text{ W}}{2\pi (0.001 \text{ m}) 0.5 \text{ m}} = 1.59 \times 10^5 \text{ W/m}^2 \quad <$$

COMMENTS: The symmetry condition at $r = 0$ imposes the requirement that $\partial T / \partial r|_{r=0} = 0$, and

hence $q''(0, t) = 0$ throughout the process. The temperature at r_o , and hence the convection heat flux, increases steadily during the start-up, and since conduction to the surface must be balanced by convection from the surface at all times, $|\partial T / \partial r|_{r=r_o}$ also increases during the start-up.

PROBLEM 3.1

KNOWN: One-dimensional, plane wall separating hot and cold fluids at $T_{\infty,1}$ and $T_{\infty,2}$, respectively.

FIND: Temperature distribution, $T(x)$, and heat flux, q''_x , in terms of $T_{\infty,1}$, $T_{\infty,2}$, h_1 , h_2 , k and L .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) Constant properties, (4) Negligible radiation, (5) No generation.

ANALYSIS: For the foregoing conditions, the general solution to the heat diffusion equation is of the form, Equation 3.2,

$$T(x) = C_1x + C_2. \quad (1)$$

The constants of integration, C_1 and C_2 , are determined by using surface energy balance conditions at $x = 0$ and $x = L$, Equation 2.32, and as illustrated above,

$$-k \frac{dT}{dx} \Big|_{x=0} = h_1 [T_{\infty,1} - T(0)] \quad -k \frac{dT}{dx} \Big|_{x=L} = h_2 [T(L) - T_{\infty,2}]. \quad (2,3)$$

For the BC at $x = 0$, Equation (2), use Equation (1) to find

$$-k(C_1 + 0) = h_1 [T_{\infty,1} - (C_1 \cdot 0 + C_2)] \quad (4)$$

and for the BC at $x = L$ to find

$$-k(C_1 + 0) = h_2 [(C_1L + C_2) - T_{\infty,2}]. \quad (5)$$

Multiply Eq. (4) by h_2 and Eq. (5) by h_1 , and add the equations to obtain C_1 . Then substitute C_1 into Eq. (4) to obtain C_2 . The results are

$$C_1 = -\frac{(T_{\infty,1} - T_{\infty,2})}{k \left[\frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k} \right]} \quad C_2 = -\frac{(T_{\infty,1} - T_{\infty,2})}{h_1 \left[\frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k} \right]} + T_{\infty,1}$$

$$T(x) = -\frac{(T_{\infty,1} - T_{\infty,2})}{\left[\frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k} \right]} \left[\frac{x}{k} + \frac{1}{h_1} \right] + T_{\infty,1}. \quad <$$

From Fourier's law, the heat flux is a constant and of the form

$$q''_x = -k \frac{dT}{dx} = -k C_1 = +\frac{(T_{\infty,1} - T_{\infty,2})}{\left[\frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k} \right]}. \quad <$$

PROBLEM 3.2

KNOWN: Temperatures and convection coefficients associated with air at the inner and outer surfaces of a rear window.

FIND: (a) Inner and outer window surface temperatures, $T_{s,i}$ and $T_{s,o}$, and (b) $T_{s,i}$ and $T_{s,o}$ as a function of the outside air temperature $T_{\infty,o}$ and for selected values of outer convection coefficient, h_o .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible radiation effects, (4) Constant properties.

PROPERTIES: Table A-3, Glass (300 K): $k = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) The heat flux may be obtained from Eqs. 3.11 and 3.12,

$$q'' = \frac{T_{\infty,i} - T_{\infty,o}}{\frac{1}{h_o} + \frac{L}{k} + \frac{1}{h_i}} = \frac{40^\circ\text{C} - (-10^\circ\text{C})}{\frac{1}{65 \text{ W/m}^2 \cdot \text{K}} + \frac{0.004 \text{ m}}{1.4 \text{ W/m}\cdot\text{K}} + \frac{1}{30 \text{ W/m}^2 \cdot \text{K}}}$$

$$q'' = \frac{50^\circ\text{C}}{(0.0154 + 0.0029 + 0.0333) \text{ m}^2 \cdot \text{K/W}} = 969 \text{ W/m}^2.$$

Hence, with $q'' = h_i (T_{\infty,i} - T_{s,o})$, the inner surface temperature is

$$T_{s,i} = T_{\infty,i} - \frac{q''}{h_i} = 40^\circ\text{C} - \frac{969 \text{ W/m}^2}{30 \text{ W/m}^2 \cdot \text{K}} = 7.7^\circ\text{C} \quad <$$

Similarly for the outer surface temperature with $q'' = h_o (T_{s,o} - T_{\infty,o})$ find

$$T_{s,o} = T_{\infty,o} + \frac{q''}{h_o} = -10^\circ\text{C} + \frac{969 \text{ W/m}^2}{65 \text{ W/m}^2 \cdot \text{K}} = 4.9^\circ\text{C} \quad <$$

(b) Using the same analysis, $T_{s,i}$ and $T_{s,o}$ have been computed and plotted as a function of the outside air temperature, $T_{\infty,o}$, for outer convection coefficients of $h_o = 2, 65$, and $100 \text{ W/m}^2 \cdot \text{K}$. As expected, $T_{s,i}$ and $T_{s,o}$ are linear with changes in the outside air temperature. The difference between $T_{s,i}$ and $T_{s,o}$ increases with increasing convection coefficient, since the heat flux through the window likewise increases. This difference is larger at lower outside air temperatures for the same reason. Note that with $h_o = 2 \text{ W/m}^2 \cdot \text{K}$, $T_{s,i} - T_{s,o}$, is too small to show on the plot.

Continued

PROBLEM 3.2 (Cont.)

COMMENTS: (1) The largest resistance is that associated with convection at the inner surface. The values of $T_{s,i}$ and $T_{s,o}$ could be increased by increasing the value of h_i .

(2) The *IHT Thermal Resistance Network Model* was used to create a model of the window and generate the above plot. The Workspace is shown below.

// Thermal Resistance Network Model:

// The Network:

// Heat rates into node j, qij, through thermal resistance Rij

$$q_{21} = (T_2 - T_1) / R_{21}$$

$$q_{32} = (T_3 - T_2) / R_{32}$$

$$q_{43} = (T_4 - T_3) / R_{43}$$

// Nodal energy balances

$$q_1 + q_{21} = 0$$

$$q_2 - q_{21} + q_{32} = 0$$

$$q_3 - q_{32} + q_{43} = 0$$

$$q_4 - q_{43} = 0$$

/* Assigned variables list: deselect the qi, Rij and Ti which are unknowns; set qi = 0 for embedded nodal points at which there is no external source of heat. */

T1 = Tinfo // Outside air temperature, C

//q1 = // Heat rate, W

T2 = Tso // Outer surface temperature, C

q2 = 0 // Heat rate, W; node 2, no external heat source

T3 = Tsi // Inner surface temperature, C

q3 = 0 // Heat rate, W; node 2, no external heat source

T4 = Tinf // Inside air temperature, C

//q4 = // Heat rate, W

// Thermal Resistances:

R21 = 1 / (ho * As) // Convection thermal resistance, K/W; outer surface

R32 = L / (k * As) // Conduction thermal resistance, K/W; glass

R43 = 1 / (hi * As) // Convection thermal resistance, K/W; inner surface

// Other Assigned Variables:

Tinfo = -10 // Outside air temperature, C

ho = 65 // Convection coefficient, W/m^2.K; outer surface

L = 0.004 // Thickness, m; glass

k = 1.4 // Thermal conductivity, W/m.K; glass

Tinf = 40 // Inside air temperature, C

hi = 30 // Convection coefficient, W/m^2.K; inner surface

As = 1 // Cross-sectional area, m^2; unit area

PROBLEM 3.3

KNOWN: Desired inner surface temperature of rear window with prescribed inside and outside air conditions.

FIND: (a) Heater power per unit area required to maintain the desired temperature, and (b) Compute and plot the electrical power requirement as a function of $T_{\infty,o}$ for the range $-30 \leq T_{\infty,o} \leq 0^\circ\text{C}$ with h_o of 2, 20, 65 and $100 \text{ W/m}^2\cdot\text{K}$. Comment on heater operation needs for low h_o . If $h \sim V^n$, where V is the vehicle speed and n is a positive exponent, how does the vehicle speed affect the need for heater operation?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Uniform heater flux, q''_h , (4) Constant properties, (5) Negligible radiation effects, (6) Negligible film resistance.

PROPERTIES: Table A-3, Glass (300 K): $k = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) From an energy balance at the inner surface and the thermal circuit, it follows that for a unit surface area,

$$\frac{T_{\infty,i} - T_{s,i}}{1/h_i} + q''_h = \frac{T_{s,i} - T_{\infty,o}}{L/k + 1/h_o}$$

$$q''_h = \frac{T_{s,i} - T_{\infty,o}}{L/k + 1/h_o} - \frac{T_{\infty,i} - T_{s,i}}{1/h_i} = \frac{15^\circ\text{C} - (-10^\circ\text{C})}{\frac{0.004 \text{ m}}{1.4 \text{ W/m}\cdot\text{K}} + \frac{1}{65 \text{ W/m}^2\cdot\text{K}}} - \frac{25^\circ\text{C} - 15^\circ\text{C}}{10 \text{ W/m}^2\cdot\text{K}}$$

$$q''_h = (1370 - 100) \text{ W/m}^2 = 1270 \text{ W/m}^2$$

(b) The heater electrical power requirement as a function of the exterior air temperature for different exterior convection coefficients is shown in the plot. When $h_o = 2 \text{ W/m}^2\cdot\text{K}$, the heater is unnecessary, since the glass is maintained at 15°C by the interior air. If $h \sim V^n$, we conclude that, with higher vehicle speeds, the exterior convection will increase, requiring increased heat power to maintain the 15°C condition.

COMMENTS: With $q''_h = 0$, the inner surface temperature with $T_{\infty,o} = -10^\circ\text{C}$ would be given by

$$\frac{T_{\infty,i} - T_{s,i}}{T_{\infty,i} - T_{\infty,o}} = \frac{1/h_i}{1/h_i + L/k + 1/h_o} = \frac{0.10}{0.118} = 0.846, \quad \text{or} \quad T_{s,i} = 25^\circ\text{C} - 0.846(35^\circ\text{C}) = -4.6^\circ\text{C}.$$

PROBLEM 3.4

KNOWN: Curing of a transparent film by radiant heating with substrate and film surface subjected to known thermal conditions.

FIND: (a) Thermal circuit for this situation, (b) Radiant heat flux, q_o'' (W/m^2), to maintain bond at curing temperature, T_o , (c) Compute and plot q_o'' as a function of the film thickness for $0 \leq L_f \leq 1$ mm, and (d) If the film is not transparent, determine q_o'' required to achieve bonding; plot results as a function of L_f .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat flow, (3) All the radiant heat flux q_o'' is absorbed at the bond, (4) Negligible contact resistance.

ANALYSIS: (a) The thermal circuit for this situation is shown at the right. Note that terms are written on a per unit area basis.

(b) Using this circuit and performing an energy balance on the film-substrate interface,

$$q_o'' = q_1'' + q_2'' \quad q_o'' = \frac{T_o - T_\infty}{R_{cv}'' + R_f''} + \frac{T_o - T_1}{R_s''}$$

where the thermal resistances are

$$R_{cv}'' = 1/h = 1/50 \text{ W/m}^2 \cdot \text{K} = 0.020 \text{ m}^2 \cdot \text{K/W}$$

$$R_f'' = L_f/k_f = 0.00025 \text{ m}/0.025 \text{ W/m} \cdot \text{K} = 0.010 \text{ m}^2 \cdot \text{K/W}$$

$$R_s'' = L_s/k_s = 0.001 \text{ m}/0.05 \text{ W/m} \cdot \text{K} = 0.020 \text{ m}^2 \cdot \text{K/W}$$

$$q_o'' = \frac{(60 - 20)^\circ \text{C}}{[0.020 + 0.010] \text{ m}^2 \cdot \text{K/W}} + \frac{(60 - 30)^\circ \text{C}}{0.020 \text{ m}^2 \cdot \text{K/W}} = (1333 + 1500) \text{ W/m}^2 = 2833 \text{ W/m}^2 <$$

(c) For the transparent film, the radiant flux required to achieve bonding as a function of film thickness L_f is shown in the plot below.

(d) If the film is opaque (not transparent), the thermal circuit is shown below. In order to find q_o'' , it is necessary to write two energy balances, one around the T_s node and the second about the T_o node.

The results of the analysis are plotted below.

Continued...

PROBLEM 3.4 (Cont.)

COMMENTS: (1) When the film is transparent, the radiant flux is absorbed on the bond. The flux required decreases with increasing film thickness. Physically, how do you explain this? Why is the relationship not linear?

(2) When the film is opaque, the radiant flux is absorbed on the surface, and the flux required increases with increasing thickness of the film. Physically, how do you explain this? Why is the relationship linear?

(3) The IHT Thermal Resistance Network Model was used to create a model of the film-substrate system and generate the above plot. The Workspace is shown below.

// Thermal Resistance Network

Model:

// The Network:

// Heat rates into node j, q_{ij} , through thermal resistance R_{ij}

$$q_{21} = (T_2 - T_1) / R_{21}$$

$$q_{32} = (T_3 - T_2) / R_{32}$$

$$q_{43} = (T_4 - T_3) / R_{43}$$

// Nodal energy balances

$$q_1 + q_{21} = 0$$

$$q_2 - q_{21} + q_{32} = 0$$

$$q_3 - q_{32} + q_{43} = 0$$

$$q_4 - q_{43} = 0$$

/* Assigned variables list: deselect the q_i , R_{ij} and T_i which are unknowns; set $q_i = 0$ for embedded nodal points at which there is no external source of heat. */

$T_1 = T_{inf}$ // Ambient air temperature, C

// $q_1 =$ // Heat rate, W; film side

$T_2 = T_s$ // Film surface temperature, C

$q_2 = 0$ // Radiant flux, W/m²; zero for part (a)

$T_3 = T_o$ // Bond temperature, C

$q_3 = q_o$ // Radiant flux, W/m²; part (a)

$T_4 = T_{sub}$ // Substrate temperature, C

// $q_4 =$ // Heat rate, W; substrate side

// Thermal Resistances:

$R_{21} = 1 / (h * A_s)$ // Convection resistance, K/W

$R_{32} = L_f / (k_f * A_s)$ // Conduction resistance, K/W; film

$R_{43} = L_s / (k_s * A_s)$ // Conduction resistance, K/W; substrate

// Other Assigned Variables:

$T_{inf} = 20$ // Ambient air temperature, C

$h = 50$ // Convection coefficient, W/m².K

$L_f = 0.00025$ // Thickness, m; film

$k_f = 0.025$ // Thermal conductivity, W/m.K; film

$T_o = 60$ // Cure temperature, C

$L_s = 0.001$ // Thickness, m; substrate

$k_s = 0.05$ // Thermal conductivity, W/m.K; substrate

$T_{sub} = 30$ // Substrate temperature, C

$A_s = 1$ // Cross-sectional area, m²; unit area

PROBLEM 3.5

KNOWN: Thicknesses and thermal conductivities of refrigerator wall materials. Inner and outer air temperatures and convection coefficients.

FIND: Heat gain per surface area.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Negligible contact resistance, (4) Negligible radiation, (5) Constant properties.

ANALYSIS: From the thermal circuit, the heat gain per unit surface area is

$$q'' = \frac{T_{\infty,o} - T_{\infty,i}}{(1/h_i) + (L_p/k_p) + (L_i/k_i) + (L_p/k_p) + (1/h_o)}$$

$$q'' = \frac{(25 - 4)^{\circ}\text{C}}{2\left(1/5 \text{ W/m}^2 \cdot \text{K}\right) + 2(0.003\text{m}/60 \text{ W/m} \cdot \text{K}) + (0.050\text{m}/0.046 \text{ W/m} \cdot \text{K})}$$

$$q'' = \frac{21^{\circ}\text{C}}{(0.4 + 0.0001 + 1.087) \text{ m}^2 \cdot \text{K/W}} = 14.1 \text{ W/m}^2 \quad <$$

COMMENTS: Although the contribution of the panels to the total thermal resistance is negligible, that due to convection is not inconsequential and is comparable to the thermal resistance of the insulation.

PROBLEM 3.6

KNOWN: Design and operating conditions of a heat flux gage.

FIND: (a) Convection coefficient for water flow ($T_s = 27^\circ\text{C}$) and error associated with neglecting conduction in the insulation, (b) Convection coefficient for air flow ($T_s = 125^\circ\text{C}$) and error associated with neglecting conduction and radiation, (c) Effect of convection coefficient on error associated with neglecting conduction for $T_s = 27^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Constant k .

ANALYSIS: (a) The electric power dissipation is balanced by convection to the water and conduction through the insulation. An energy balance applied to a control surface about the foil therefore yields

$$P''_{elec} = q''_{conv} + q''_{cond} = h(T_s - T_\infty) + k(T_s - T_b)/L$$

Hence,

$$h = \frac{P''_{elec} - k(T_s - T_b)/L}{T_s - T_\infty} = \frac{2000 \text{ W/m}^2 - 0.04 \text{ W/m} \cdot \text{K} (2 \text{ K}) / 0.01 \text{ m}}{2 \text{ K}}$$

$$h = \frac{(2000 - 8) \text{ W/m}^2}{2 \text{ K}} = 996 \text{ W/m}^2 \cdot \text{K}$$

If conduction is neglected, a value of $h = 1000 \text{ W/m}^2 \cdot \text{K}$ is obtained, with an attendant error of $(1000 - 996)/996 = 0.40\%$

(b) In air, energy may also be transferred from the foil surface by radiation, and the energy balance yields

$$P''_{elec} = q''_{conv} + q''_{rad} + q''_{cond} = h(T_s - T_\infty) + \varepsilon\sigma(T_s^4 - T_{sur}^4) + k(T_s - T_b)/L$$

Hence,

$$h = \frac{P''_{elec} - \varepsilon\sigma(T_s^4 - T_{sur}^4) - k(T_s - T_\infty)/L}{T_s - T_\infty}$$

$$= \frac{2000 \text{ W/m}^2 - 0.15 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (398^4 - 298^4) \text{ K}^4 - 0.04 \text{ W/m} \cdot \text{K} (100 \text{ K}) / 0.01 \text{ m}}{100 \text{ K}}$$

$$= \frac{(2000 - 146 - 400) \text{ W/m}^2}{100 \text{ K}} = 14.5 \text{ W/m}^2 \cdot \text{K}$$

Continued...

PROBLEM 3.6 (Cont.)

If conduction, radiation, or conduction and radiation are neglected, the corresponding values of h and the percentage errors are $18.5 \text{ W/m}^2\cdot\text{K}$ (27.6%), $16 \text{ W/m}^2\cdot\text{K}$ (10.3%), and $20 \text{ W/m}^2\cdot\text{K}$ (37.9%).

(c) For a fixed value of $T_s = 27^\circ\text{C}$, the conduction loss remains at $q''_{\text{cond}} = 8 \text{ W/m}^2$, which is also the fixed difference between P''_{elec} and q''_{conv} . Although this difference is not clearly shown in the plot for $10 \leq h \leq 1000 \text{ W/m}^2\cdot\text{K}$, it is revealed in the subplot for $10 \leq 100 \text{ W/m}^2\cdot\text{K}$.

Errors associated with neglecting conduction decrease with increasing h from values which are significant for small h ($h < 100 \text{ W/m}^2\cdot\text{K}$) to values which are negligible for large h .

COMMENTS: In liquids (large h), it is an excellent approximation to neglect conduction and assume that all of the dissipated power is transferred to the fluid.

PROBLEM 3.7

KNOWN: A layer of fatty tissue with fixed inside temperature can experience different outside convection conditions.

FIND: (a) Ratio of heat loss for different convection conditions, (b) Outer surface temperature for different convection conditions, and (c) Temperature of still air which achieves same cooling as moving air (*wind chill* effect).

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction through a plane wall, (2) Steady-state conditions, (3) Homogeneous medium with constant properties, (4) No internal heat generation (metabolic effects are negligible), (5) Negligible radiation effects.

PROPERTIES: Table A-3, Tissue, fat layer: $k = 0.2 \text{ W/m}\cdot\text{K}$.

ANALYSIS: The thermal circuit for this situation is

Hence, the heat rate is

$$q = \frac{T_{s,1} - T_{\infty}}{R_{\text{tot}}} = \frac{T_{s,1} - T_{\infty}}{L/kA + 1/hA}.$$

Therefore,

$$\frac{q''_{\text{calm}}}{q''_{\text{windy}}} = \frac{\left[\frac{L}{k} + \frac{1}{h} \right]_{\text{windy}}}{\left[\frac{L}{k} + \frac{1}{h} \right]_{\text{calm}}}.$$

Applying a surface energy balance to the outer surface, it also follows that

$$q''_{\text{cond}} = q''_{\text{conv}}.$$

Continued

PROBLEM 3.7 (Cont.)

Hence,

$$\frac{k}{L}(T_{s,1} - T_{s,2}) = h(T_{s,2} - T_{\infty})$$

$$T_{s,2} = \frac{T_{\infty} + \frac{k}{hL}T_{s,1}}{1 + \frac{k}{hL}}$$

To determine the wind chill effect, we must determine the heat loss for the windy day and use it to evaluate the hypothetical ambient air temperature, T'_{∞} , which would provide the same heat loss on a calm day, Hence,

$$q'' = \frac{T_{s,1} - T_{\infty}}{\left[\frac{L}{k} + \frac{1}{h}\right]_{\text{windy}}} = \frac{T_{s,1} - T'_{\infty}}{\left[\frac{L}{k} + \frac{1}{h}\right]_{\text{calm}}}$$

From these relations, we can now find the results sought:

$$(a) \quad \frac{q''_{\text{calm}}}{q''_{\text{windy}}} = \frac{\frac{0.003 \text{ m}}{0.2 \text{ W/m} \cdot \text{K}} + \frac{1}{65 \text{ W/m}^2 \cdot \text{K}}}{\frac{0.003 \text{ m}}{0.2 \text{ W/m} \cdot \text{K}} + \frac{1}{25 \text{ W/m}^2 \cdot \text{K}}} = \frac{0.015 + 0.0154}{0.015 + 0.04}$$

$$\frac{q''_{\text{calm}}}{q''_{\text{windy}}} = 0.553 \quad <$$

$$(b) \quad T_{s,2}]_{\text{calm}} = \frac{-15^{\circ}\text{C} + \frac{0.2 \text{ W/m} \cdot \text{K}}{(25 \text{ W/m}^2 \cdot \text{K})(0.003 \text{ m})} 36^{\circ}\text{C}}{1 + \frac{0.2 \text{ W/m} \cdot \text{K}}{(25 \text{ W/m}^2 \cdot \text{K})(0.003 \text{ m})}} = 22.1^{\circ}\text{C} \quad <$$

$$T_{s,2}]_{\text{windy}} = \frac{-15^{\circ}\text{C} + \frac{0.2 \text{ W/m} \cdot \text{K}}{(65 \text{ W/m}^2 \cdot \text{K})(0.003 \text{ m})} 36^{\circ}\text{C}}{1 + \frac{0.2 \text{ W/m} \cdot \text{K}}{(65 \text{ W/m}^2 \cdot \text{K})(0.003 \text{ m})}} = 10.8^{\circ}\text{C} \quad <$$

$$(c) \quad T'_{\infty} = 36^{\circ}\text{C} - (36 + 15)^{\circ}\text{C} \frac{(0.003/0.2 + 1/25)}{(0.003/0.2 + 1/65)} = -56.3^{\circ}\text{C} \quad <$$

COMMENTS: The wind chill effect is equivalent to a decrease of $T_{s,2}$ by 11.3°C and increase in the heat loss by a factor of $(0.553)^{-1} = 1.81$.

PROBLEM 3.8

KNOWN: Dimensions of a thermopane window. Room and ambient air conditions.

FIND: (a) Heat loss through window, (b) Effect of variation in outside convection coefficient for double and triple pane construction.

SCHEMATIC (Double pane):

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Neglect radiation effects, (5) Air between glass is stagnant.

PROPERTIES: Table A-3, Glass (300 K): $k_g = 1.4 \text{ W/m}\cdot\text{K}$; Table A-4, Air ($T = 278 \text{ K}$): $k_a = 0.0245 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) From the thermal circuit, the heat loss is

$$q = \frac{T_{\infty,i} - T_{\infty,o}}{\frac{1}{A} \left(\frac{1}{h_i} + \frac{L}{k_g} + \frac{L}{k_a} + \frac{L}{k_g} + \frac{1}{h_o} \right)}$$

$$q = \frac{20^\circ\text{C} - (-10^\circ\text{C})}{\left(\frac{1}{0.4\text{m}^2} \right) \left(\frac{1}{10\text{W/m}^2\cdot\text{K}} + \frac{0.007\text{m}}{1.4\text{W/m}\cdot\text{K}} + \frac{0.007\text{m}}{0.0245\text{W/m}\cdot\text{K}} + \frac{0.007\text{m}}{1.4\text{W/m}\cdot\text{K}} + \frac{1}{80\text{W/m}^2\cdot\text{K}} \right)}$$

$$q = \frac{30^\circ\text{C}}{(0.25 + 0.0125 + 0.715 + 0.0125 + 0.03125)\text{K/W}} = \frac{30^\circ\text{C}}{1.021\text{K/W}} = 29.4 \text{ W}$$

(b) For the triple pane window, the additional pane and airspace increase the total resistance from 1.021 K/W to 1.749 K/W, thereby reducing the heat loss from 29.4 to 17.2 W. The effect of h_o on the heat loss is plotted as follows.

Continued...

PROBLEM 3.8(Cont.)

Changes in h_o influence the heat loss at small values of h_o , for which the outside convection resistance is not negligible relative to the total resistance. However, the resistance becomes negligible with increasing h_o , particularly for the triple pane window, and changes in h_o have little effect on the heat loss.

COMMENTS: (1) The largest contribution to the thermal resistance is due to conduction across the enclosed air. Note that this air could be in motion due to free convection currents. If the corresponding convection coefficient exceeded $3.5 \text{ W/m}^2\cdot\text{K}$, the thermal resistance would be less than that predicted by assuming conduction across stagnant air, thereby increasing the heat loss. (2) Determination of the radiation heat loss is complex and will be addressed in Chapters 12 and 13. Radiation would increase the heat loss between the room and outside air, but on a sunny day, solar radiation transmitted through the window would contribute to heating the room.

PROBLEM 3.9

KNOWN: Thicknesses of three materials which form a composite wall and thermal conductivities of two of the materials. Inner and outer surface temperatures of the composite; also, temperature and convection coefficient associated with adjoining gas.

FIND: Value of unknown thermal conductivity, k_B .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Negligible radiation effects.

ANALYSIS: Referring to the thermal circuit, the heat flux may be expressed as

$$q'' = \frac{T_{s,i} - T_{s,o}}{\frac{L_A}{k_A} + \frac{L_B}{k_B} + \frac{L_C}{k_C}} = \frac{(600 - 20)^{\circ}\text{C}}{\frac{0.3 \text{ m}}{20 \text{ W/m} \cdot \text{K}} + \frac{0.15 \text{ m}}{k_B} + \frac{0.15 \text{ m}}{50 \text{ W/m} \cdot \text{K}}}$$

$$q'' = \frac{580}{0.018 + 0.15/k_B} \text{ W/m}^2. \quad (1)$$

The heat flux may be obtained from

$$q'' = h(T_{\infty} - T_{s,i}) = 25 \text{ W/m}^2 \cdot \text{K} (800 - 600)^{\circ}\text{C} \quad (2)$$

$$q'' = 5000 \text{ W/m}^2.$$

Substituting for the heat flux from Eq. (2) into Eq. (1), find

$$\frac{0.15}{k_B} = \frac{580}{q''} - 0.018 = \frac{580}{5000} - 0.018 = 0.098$$

$$k_B = 1.53 \text{ W/m} \cdot \text{K}. \quad <$$

COMMENTS: Radiation effects are likely to have a significant influence on the net heat flux at the inner surface of the oven.

PROBLEM 3.10

KNOWN: Construction and dimensions of a device to measure the temperature dependence of a liquid's thermal conductivity.

FIND: (a) Overall height of the apparatus using bakelite, (b) Overall height of the apparatus using aerogel, (c) Required heater area and electrical power to minimize heat losses for bakelite and aerogel.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer.

PROPERTIES: Table A.3, bakelite (300 K): $k = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: The heat flux through the device is constant and is evaluated using Eq. 3.5

$$q'' = k_\ell \frac{\Delta T_\ell}{t_\ell} = \frac{0.8 \text{ W/m}\cdot\text{K} \times 2^\circ\text{C}}{2 \times 10^{-3} \text{ m}} = 800 \text{ W/m}^2$$

For each stainless steel sheet,

$$q'' = k_{ss} \frac{\Delta T_{ss}}{t_{ss}} \quad \text{or} \quad \Delta T_{ss} = \frac{q'' t_{ss}}{k_{ss}} = \frac{800 \text{ W/m}^2 \times 1 \times 10^{-3} \text{ m}}{15 \text{ W/m}\cdot\text{K}} = 0.053^\circ\text{C}$$

The temperature difference from top to bottom is

$$\Delta T_{\text{tot}} = \Delta T_{ss} \times N \times 2 + \Delta T_\ell \times N + \Delta T_{\text{lcm}} \times (N - 1)$$

or

$$\Delta T_{\text{lcm}} = \frac{1}{(N - 1)} [\Delta T_{\text{tot}} - \Delta T_{ss} \times N \times 2 - \Delta T_\ell \times N] = \frac{1}{4} [100^\circ\text{C} - 0.053^\circ\text{C} \times 10 - 2^\circ\text{C} \times 5] = 22.4^\circ\text{C}$$

For the low thermal conductivity material, $q'' = k_{\text{lcm}} \frac{\Delta T_{\text{lcm}}}{t_{\text{lcm}}}$ or $t_{\text{lcm}} = \frac{k_{\text{lcm}} \Delta T_{\text{lcm}}}{q''}$.

(a) For bakelite,

$$t_{\text{lcm}} = \frac{1.4 \text{ W/m}\cdot\text{K} \times 22.4^\circ\text{C}}{800 \text{ W/m}^2} = 39.2 \times 10^{-3} \text{ m}$$

Continued...

PROBLEM 3.10 (Cont.)

The total height is

$$\begin{aligned} H &= 2Nt_{ss} + Nt_{\ell} + (N - 1)t_{lcm} \\ &= 2 \times 5 \times 1 \times 10^{-3} \text{ m} + 5 \times 2 \times 10^{-3} \text{ m} + (5 - 1) \times 39.2 \times 10^{-3} \text{ m} \\ &= 177 \times 10^{-3} \text{ m} = 177 \text{ mm} \end{aligned} \quad <$$

(b) For aerogel,

$$t_{lcm} = \frac{0.0065 \text{ W/m} \cdot \text{K} \times 22.4^{\circ}\text{C}}{800 \text{ W/m}^2} = 182 \times 10^{-6} \text{ m} = 182 \text{ } \mu\text{m}$$

The total height is

$$\begin{aligned} H &= 2N \times t_{ss} + Nt_{\ell} + (N - 1)t_{lcm} \\ &= 2 \times 5 \times 1 \times 10^{-3} \text{ m} + 5 \times 2 \times 10^{-3} \text{ m} + (5 - 1) \times 182 \times 10^{-6} \text{ m} \\ &= 20.7 \times 10^{-3} \text{ m} = 20.7 \text{ mm} \end{aligned} \quad <$$

(c) For side area, $A_s = 4HL$ and heater area, $A_h = L^2$. The heater-to-side area ratio is

$$10 = \frac{L^2}{4HL} = \frac{L}{4H} \quad \text{or } L = 40 H$$

For bakelite, $L = 40 \times 177 \text{ mm} = 7.1 \text{ m}$ and

$$q = q''A_h = 800 \text{ W/m}^2 \times (7.1 \text{ m})^2 = 40.3 \times 10^3 \text{ W} = 40.3 \text{ kW} \quad <$$

For aerogel, $L = 40 \times 20.7 \text{ mm} = 830 \text{ mm} = 0.83 \text{ m}$ and

$$q = q''A_h = 800 \text{ W/m}^2 \times (0.83 \text{ m})^2 = 550 \text{ W} \quad <$$

COMMENTS: (1) It may be expected that the small device utilizing the aerogel low thermal conductivity material will reach steady-state faster than the large device using the bakelite plates. (2) The stainless steel sheets are isothermal to within 0.053 degrees Celsius. Precise placement of the thermocouple beads on the stainless steel sheets is not required. (3) The device constructed of bakelite is large. The device constructed of the nanostructured aerogel material reasonably sized.

PROBLEM 3.11

KNOWN: Drying oven wall having material with known thermal conductivity sandwiched between thin metal sheets. Radiation and convection conditions prescribed on inner surface; convection conditions on outer surface.

FIND: (a) Thermal circuit representing wall and processes and (b) Insulation thickness required to maintain outer wall surface at $T_o = 40^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in wall, (3) Thermal resistance of metal sheets negligible, (4) Negligible contact resistance.

ANALYSIS: (a) The thermal circuit is shown above. Note labels for the temperatures, thermal resistances and the relevant heat fluxes.

(b) Perform energy balances on the i- and o- nodes finding

$$\frac{T_{\infty,i} - T_i}{R''_{cv,i}} + \frac{T_o - T_i}{R''_{cd}} + q''_{rad} = 0 \quad (1)$$

$$\frac{T_i - T_o}{R''_{cd}} + \frac{T_{\infty,o} - T_o}{R''_{cv,o}} = 0 \quad (2)$$

where the thermal resistances are

$$R''_{cv,i} = 1/h_i = 0.0333 \text{ m}^2 \cdot \text{K} / \text{W} \quad (3)$$

$$R''_{cd} = L/k = L/0.05 \text{ m}^2 \cdot \text{K} / \text{W} \quad (4)$$

$$R''_{cv,o} = 1/h_o = 0.100 \text{ m}^2 \cdot \text{K} / \text{W} \quad (5)$$

Substituting numerical values, and solving Eqs. (1) and (2) simultaneously, find

$$L = 86 \text{ mm}$$

COMMENTS: (1) The temperature at the inner surface can be found from an energy balance on the i-node using the value found for L.

$$\frac{T_{\infty,i} - T_i}{R''_{cv,i}} + \frac{T_{\infty,o} - T_i}{R''_{cd} + R''_{cv,i}} + q''_{rad} = 0 \quad T_i = 298.3^\circ\text{C}$$

It follows that T_i is close to $T_{\infty,i}$ since the wall represents the dominant resistance of the system.

(2) Verify that $q''_i = 50 \text{ W/m}^2$ and $q''_o = -150 \text{ W/m}^2$. Is the overall energy balance on the system satisfied?

PROBLEM 3.12

KNOWN: Dimensions and thermal conductivities of the components of a fuel cell membrane.

FIND: The effective thermal conductivity in the x-direction for various carbon nanotube loadings.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

ANALYSIS: The equivalent thermal circuit is as follows.

Therefore,

$$q_x = \frac{T_1 - T_2}{R_{tot}} = \frac{\Delta T}{R_{tot}} = \Delta T \left[\frac{1}{R_{t,1}} + \frac{1}{R_{t,2}} + \frac{1}{R_{t,3}} + \frac{1}{R_{t,4}} \right] ; \quad q_x = k_{eff,x} \frac{wt}{L} \Delta T \quad (1, 2)$$

Continued...

PROBLEM 3.12 (Cont.)

Equating Eqs. (1) and (2) yields

$$k_{\text{eff},x} = \frac{L}{wt} \left[\frac{k_{\text{gdl}}(2t_{\text{gdl}})w}{L} + \frac{k_{\text{pc}}t_{\text{pc}}w}{L} + \frac{k_{\text{cl}}(1-f)2t_{\text{cl}}w}{L} + \frac{k_{\text{cn}}f2t_{\text{cl}}w}{L} \right]$$

$$k_{\text{eff},x} = \frac{1}{t} \left[2k_{\text{gdl}}t_{\text{gdl}} + k_{\text{pc}}t_{\text{pc}} + 2k_{\text{cl}}(1-f)t_{\text{cl}} + 2k_{\text{cn}}ft_{\text{cl}} \right]$$

where $t = t_{\text{pc}} + 2t_{\text{cl}} + 2t_{\text{gdl}} = 0.20 \text{ mm} + 2 \times 0.01 \text{ mm} + 2 \times 0.1 \text{ mm} = 0.42 \text{ mm}$

For $f = 0$,

$$k_{\text{eff},x} = \frac{1}{0.42 \times 10^{-3} \text{ m}} \left[\begin{array}{l} 2 \times 1.3 \text{ W/m} \cdot \text{K} \times 0.1 \times 10^{-3} \text{ m} + 0.25 \text{ W/m} \cdot \text{K} \times 0.2 \times 10^{-3} \text{ m} \\ + 2 \times 1 \text{ W/m} \cdot \text{K} \times 0.01 \times 10^{-3} \text{ m} + 0 \end{array} \right]$$

$$= 0.79 \text{ W/m} \cdot \text{K} \quad <$$

For $f = 0.3$,

$$k_{\text{eff},x} = \frac{1}{0.42 \times 10^{-3} \text{ m}} \left[\begin{array}{l} 2 \times 1.3 \text{ W/m} \cdot \text{K} \times 0.1 \times 10^{-3} \text{ m} + 0.25 \text{ W/m} \cdot \text{K} \times 0.2 \times 10^{-3} \text{ m} \\ + 2 \times 1 \text{ W/m} \cdot \text{K} \times (1 - 0.3) \times 0.01 \times 10^{-3} \text{ m} \\ + 2 \times 3000 \text{ W/m} \cdot \text{K} \times (0.3) \times 0.01 \times 10^{-3} \text{ m} \end{array} \right]$$

$$= 43.6 \text{ W/m} \cdot \text{K} \quad <$$

Similarly, $k_{\text{eff},x} = 15.1 \text{ W/m}^2 \cdot \text{K}$ and $29.3 \text{ W/m}^2 \cdot \text{K}$ for $f = 0.1$ and 0.2 , respectively.

COMMENTS: (1) Addition of a small amount of high thermal conductivity carbon nanotubes increases the ability of the membrane to conduct energy in the x-direction. (2) The effective thermal conductivity in the y-direction will not be significantly affected by the carbon nanotubes, since the thermal resistance posed by the polymer core will have the most influence on the value of $k_{\text{eff},y}$.

PROBLEM 3.13

KNOWN: Composite wall of a house with prescribed convection processes at inner and outer surfaces.

FIND: (a) Expression for thermal resistance of house wall, R_{tot} ; (b) Total heat loss, $q(W)$; (c) Effect on heat loss due to increase in outside heat transfer convection coefficient, h_o ; and (d) Controlling resistance for heat loss from house.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) Negligible contact resistance.

PROPERTIES: Table A-3, $\left(\bar{T} = (T_i + T_o)/2 = (20 - 15)^\circ\text{C}/2 = 2.5^\circ\text{C} \approx 300\text{K}\right)$: Fiberglass blanket, 28 kg/m^3 , $k_b = 0.038 \text{ W/m}\cdot\text{K}$; Plywood siding, $k_s = 0.12 \text{ W/m}\cdot\text{K}$; Plasterboard, $k_p = 0.17 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) The expression for the total thermal resistance of the house wall follows from Eq. 3.18.

$$R_{\text{tot}} = \frac{1}{h_i A} + \frac{L_p}{k_p A} + \frac{L_b}{k_b A} + \frac{L_s}{k_s A} + \frac{1}{h_o A} \quad <$$

(b) The total heat loss through the house wall is

$$q = \Delta T / R_{\text{tot}} = (T_i - T_o) / R_{\text{tot}}.$$

Substituting numerical values, find

$$R_{\text{tot}} = \frac{1}{30 \text{ W/m}^2 \cdot \text{K} \times 350 \text{ m}^2} + \frac{0.01 \text{ m}}{0.17 \text{ W/m} \cdot \text{K} \times 350 \text{ m}^2} + \frac{0.10 \text{ m}}{0.038 \text{ W/m} \cdot \text{K} \times 350 \text{ m}^2} + \frac{0.02 \text{ m}}{0.12 \text{ W/m} \cdot \text{K} \times 350 \text{ m}^2} + \frac{1}{60 \text{ W/m}^2 \cdot \text{K} \times 350 \text{ m}^2}$$

$$R_{\text{tot}} = [9.52 + 16.8 + 752 + 47.6 + 4.76] \times 10^{-5} \text{ }^\circ\text{C/W} = 831 \times 10^{-5} \text{ }^\circ\text{C/W}$$

The heat loss is then,

$$q = [20 - (-15)]^\circ\text{C} / 831 \times 10^{-5} \text{ }^\circ\text{C/W} = 4.21 \text{ kW}. \quad <$$

(c) If h_o changes from 60 to $300 \text{ W/m}^2\cdot\text{K}$, $R_o = 1/h_o A$ changes from $4.76 \times 10^{-5} \text{ }^\circ\text{C/W}$ to $0.95 \times 10^{-5} \text{ }^\circ\text{C/W}$. This reduces R_{tot} to $826 \times 10^{-5} \text{ }^\circ\text{C/W}$, which is a 0.6% decrease and hence a 0.6% increase in q .

(d) From the expression for R_{tot} in part (b), note that the insulation resistance, $L_b/k_b A$, is $752/830 \approx 90\%$ of the total resistance. Hence, this material layer controls the resistance of the wall. From part (c) note that a 5-fold decrease in the outer convection resistance due to an increase in the wind velocity has a negligible effect on the heat loss.

PROBLEM 3.14

KNOWN: Composite wall of a house with prescribed convection processes at inner and outer surfaces.

FIND: Daily heat loss for prescribed diurnal variation in ambient air temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction (negligible change in wall thermal energy storage over 24h period), (2) Negligible contact resistance.

PROPERTIES: Table A-3, $T \approx 300$ K: Fiberglass blanket (28 kg/m^3), $k_b = 0.038 \text{ W/m}\cdot\text{K}$; Plywood, $k_s = 0.12 \text{ W/m}\cdot\text{K}$; Plasterboard, $k_p = 0.17 \text{ W/m}\cdot\text{K}$.

ANALYSIS: The heat loss may be approximated as $Q = \int_0^{24\text{h}} \frac{T_{\infty,i} - T_{\infty,o}}{R_{\text{tot}}} dt$ where

$$R_{\text{tot}} = \frac{1}{A} \left[\frac{1}{h_i} + \frac{L_p}{k_p} + \frac{L_b}{k_b} + \frac{L_s}{k_s} + \frac{1}{h_o} \right]$$

$$R_{\text{tot}} = \frac{1}{200 \text{ m}^2} \left[\frac{1}{30 \text{ W/m}^2 \cdot \text{K}} + \frac{0.01 \text{ m}}{0.17 \text{ W/m}\cdot\text{K}} + \frac{0.1 \text{ m}}{0.038 \text{ W/m}\cdot\text{K}} + \frac{0.02 \text{ m}}{0.12 \text{ W/m}\cdot\text{K}} + \frac{1}{60 \text{ W/m}^2 \cdot \text{K}} \right]$$

$$R_{\text{tot}} = 0.01454 \text{ K/W}$$

Hence the heat rate is

$$Q = \frac{1}{R_{\text{tot}}} \left\{ \int_0^{12\text{h}} \left[293 - \left[273 + 5 \sin \frac{2\pi}{24} t \right] \right] dt + \int_{12}^{24\text{h}} \left[293 - \left[273 + 11 \sin \frac{2\pi}{24} t \right] \right] dt \right\}$$

$$Q = 68.8 \frac{\text{W}}{\text{K}} \left\{ \left[20t + 5 \left[\frac{24}{2\pi} \right] \cos \frac{2\pi t}{24} \right] \Big|_0^{12} + \left[20t + 11 \left[\frac{24}{2\pi} \right] \cos \frac{2\pi t}{24} \right] \Big|_{12}^{24} \right\} \text{ K} \cdot \text{h}$$

$$Q = 68.8 \left\{ \left[240 + \frac{60}{\pi} (-1 - 1) \right] + \left[480 - 240 + \frac{132}{\pi} (1 + 1) \right] \right\} \text{ W} \cdot \text{h}$$

$$Q = 68.8 \{ 480 - 38.2 + 84.03 \} \text{ W} \cdot \text{h}$$

$$Q = 36.18 \text{ kW} \cdot \text{h} = 1.302 \times 10^8 \text{ J}$$

<

COMMENTS: From knowledge of the fuel cost, the total daily heating bill could be determined. For example, at a cost of 0.10\$/kW·h, the heating bill would be \$3.62/day.

PROBLEM 3.15

KNOWN: Dimensions and materials associated with a composite wall ($2.5\text{m} \times 6.5\text{m}$, 10 studs each 2.5m high).

FIND: Wall thermal resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Temperature of composite depends only on x (surfaces normal to x are isothermal), (3) Constant properties, (4) Negligible contact resistance.

PROPERTIES: Table A-3 ($T \approx 300\text{K}$): Hardwood siding, $k_A = 0.094\text{ W/m}\cdot\text{K}$; Hardwood, $k_B = 0.16\text{ W/m}\cdot\text{K}$; Gypsum, $k_C = 0.17\text{ W/m}\cdot\text{K}$; Insulation (glass fiber paper faced, 28 kg/m^3), $k_D = 0.038\text{ W/m}\cdot\text{K}$.

ANALYSIS: Using the isothermal surface assumption, the thermal circuit associated with a single unit (enclosed by dashed lines) of the wall is

$$(L_A / k_A A_A) = \frac{0.008\text{m}}{0.094\text{ W/m}\cdot\text{K} (0.65\text{m} \times 2.5\text{m})} = 0.0524\text{ K/W}$$

$$(L_B / k_B A_B) = \frac{0.13\text{m}}{0.16\text{ W/m}\cdot\text{K} (0.04\text{m} \times 2.5\text{m})} = 8.125\text{ K/W}$$

$$(L_D / k_D A_D) = \frac{0.13\text{m}}{0.038\text{ W/m}\cdot\text{K} (0.61\text{m} \times 2.5\text{m})} = 2.243\text{ K/W}$$

$$(L_C / k_C A_C) = \frac{0.012\text{m}}{0.17\text{ W/m}\cdot\text{K} (0.65\text{m} \times 2.5\text{m})} = 0.0434\text{ K/W}$$

The equivalent resistance of the core is

$$R_{eq} = (1/R_B + 1/R_D)^{-1} = (1/8.125 + 1/2.243)^{-1} = 1.758\text{ K/W}$$

and the total unit resistance is

$$R_{tot,1} = R_A + R_{eq} + R_C = 1.854\text{ K/W}$$

With 10 such units in parallel, the total wall resistance is

$$R_{tot} = (10 \times 1/R_{tot,1})^{-1} = 0.1854\text{ K/W}$$

COMMENTS: If surfaces parallel to the heat flow direction are assumed adiabatic, the thermal circuit and the value of R_{tot} will differ.

PROBLEM 3.16

KNOWN: Conditions associated with maintaining heated and cooled conditions within a refrigerator compartment.

FIND: Coefficient of performance (COP).

SCHEMATIC:

$$\begin{aligned} \longrightarrow T_{\infty} &= 20^{\circ}\text{C} \\ \longrightarrow h &= 50 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

ASSUMPTIONS: (1) Steady-state operating conditions, (2) Negligible radiation, (3) Compartment completely sealed from ambient air.

ANALYSIS: The Case (a) experiment is performed to determine the overall thermal resistance to heat transfer between the interior of the refrigerator and the ambient air. Applying an energy balance to a control surface about the refrigerator, it follows from Eq. 1.11b that, at any instant,

$$\dot{E}_g - \dot{E}_{\text{out}} = 0$$

Hence,

$$q_{\text{elec}} - q_{\text{out}} = 0$$

where $q_{\text{out}} = (T_{\infty,i} - T_{\infty,o})/R_t$. It follows that

$$R_t = \frac{T_{\infty,i} - T_{\infty,o}}{q_{\text{elec}}} = \frac{(90 - 25)^{\circ}\text{C}}{20 \text{ W}} = 3.25^{\circ}\text{C/W}$$

For Case (b), heat transfer from the ambient air to the compartment (the heat load) is balanced by heat transfer to the refrigerant ($q_{\text{in}} = q_{\text{out}}$). Hence, the thermal energy transferred from the refrigerator over the 12 hour period is

$$Q_{\text{out}} = q_{\text{out}}\Delta t = q_{\text{in}}\Delta t = \frac{T_{\infty,i} - T_{\infty,o}}{R_t}\Delta t$$

$$Q_{\text{out}} = \frac{(25 - 5)^{\circ}\text{C}}{3.25^{\circ}\text{C/W}}(12 \text{ h} \times 3600 \text{ s/h}) = 266,000 \text{ J}$$

The coefficient of performance (COP) is therefore

$$\text{COP} = \frac{Q_{\text{out}}}{W_{\text{in}}} = \frac{266,000}{125,000} = 2.13$$

COMMENTS: The ideal (Carnot) COP is

$$\text{COP}_{\text{ideal}} = \frac{T_c}{T_h - T_c} = \frac{278 \text{ K}}{(298 - 278) \text{ K}} = 13.9$$

and the system is operating well below its peak possible performance.

<

PROBLEM 3.17

KNOWN: Total floor space and vertical distance between floors for a square, flat roof building.

FIND: (a) Expression for width of building which minimizes heat loss, (b) Width and number of floors which minimize heat loss for a prescribed floor space and distance between floors. Corresponding heat loss, percent heat loss reduction from 2 floors.

SCHEMATIC:

ASSUMPTIONS: Negligible heat loss to ground.

ANALYSIS: (a) To minimize the heat loss q , the exterior surface area, A_s , must be minimized. From Fig. (a)

$$A_s = W^2 + 4WH = W^2 + 4WN_f H_f$$

where

$$N_f = A_f / W^2$$

Hence,

$$A_s = W^2 + 4WA_f H_f / W^2 = W^2 + 4A_f H_f / W$$

The optimum value of W corresponds to

$$\frac{dA_s}{dW} = 2W - \frac{4A_f H_f}{W^2} = 0$$

or

$$W_{\text{op}} = (2A_f H_f)^{1/3}$$

<

The competing effects of W on the areas of the roof and sidewalls, and hence the basis for an optimum, is shown schematically in Fig. (b).

(b) For $A_f = 32,768 \text{ m}^2$ and $H_f = 4$ m,

$$W_{\text{op}} = (2 \times 32,768 \text{ m}^2 \times 4 \text{ m})^{1/3} = 64 \text{ m}$$

<

Continued

PROBLEM 3.17 (Cont.)

Hence,

$$N_f = \frac{A_f}{W^2} = \frac{32,768 \text{ m}^2}{(64 \text{ m})^2} = 8 \quad <$$

and

$$q = UA_s \Delta T = 1 \text{ W/m}^2 \cdot \text{K} \left[(64 \text{ m})^2 + \frac{4 \times 32,768 \text{ m}^2 \times 4 \text{ m}}{64 \text{ m}} \right] 25^\circ \text{C} = 307,200 \text{ W} \quad <$$

For $N_f = 2$,

$$W = (A_f/N_f)^{1/2} = (32,768 \text{ m}^2/2)^{1/2} = 128 \text{ m}$$
$$q = 1 \text{ W/m}^2 \cdot \text{K} \left[(128 \text{ m})^2 + \frac{4 \times 32,768 \text{ m}^2 \times 4 \text{ m}}{128 \text{ m}} \right] 25^\circ \text{C} = 512,000 \text{ W}$$

$$\% \text{ reduction in } q = (512,000 - 307,200)/512,000 = 40\% \quad <$$

COMMENTS: Even the minimum heat loss is excessive and could be reduced by reducing U .

PROBLEM 3.18

KNOWN: Dimensions and temperature of a canister containing a solid oxide fuel cell. Surroundings and ambient temperature.

FIND: (a) Required insulation thickness to keep the equivalent blackbody temperature below 305 K, (b) Canister surface temperature for four cases, (c) Heat flux through the cylindrical walls for four cases.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Large surroundings.

ANALYSIS: The maximum allowable surface temperature may be found by relating the actual and inferred surface temperatures through the relation

$$E_s = E_b = \epsilon_s \sigma T_s^4 = \sigma T_b^4 \quad \text{or} \quad T_s = (T_b^4 / \epsilon_s)^{1/4} \quad (1)$$

The thermal circuit is

where, from Eq. 1.9,

$$h_r = \epsilon_s \sigma (T_s + T_{sur})(T_s^2 + T_{sur}^2) \quad (2)$$

Summing currents at the T_s node yields

Continued...

PROBLEM 3.18 (Cont.)

$$\frac{T_{fc} - T_s}{\left[\frac{\ln(r_2 / r_1)}{2\pi k L} \right]} = \frac{T_s - T_\infty}{\left[\frac{1}{h_2 \pi r_2 L} \right]} + \frac{T_s - T_{sur}}{\left[\frac{1}{h_r \pi r_2 L} \right]} \quad (3)$$

where

$$q = \frac{T_{fc} - T_s}{\left[\frac{\ln(r_2 / r_1)}{2\pi / L} \right]} L \quad (4)$$

Noting that the insulation thickness is $t = r_2 - r_1$, solving Eqs. (2) and (3) simultaneously, and then solving Eq. (4) yields the following results.

ϵ_s	k (W/m·K)	t (m)	T_s (K)	q (W)
0.08	0.09	0.0875	573.5	135
0.9	0.09	0.963	313.1	33.75
0.08	0.006	0.0008	573.5	108.4
0.9	0.006	0.015	313.1	10.2

COMMENTS: (1) Use of the low emissivity surface allows surface temperatures to be high without the fuel cell being detected. (2) The high surface temperature is not safe to the touch. (3) The low thermal conductivity of the aerogel allows the use of a small insulation thickness relative to the calcium silicate. (4) Small heat losses and low surface temperatures are desired. The $\epsilon_s = 0.9$, $k = 0.006$ case offers the best performance, and the surface need not be kept in a polished condition to avoid detection.

PROBLEM 3.19

KNOWN: Representative dimensions and thermal conductivities for the layers of fire-fighter's protective clothing, a turnout coat.

FIND: (a) Thermal circuit representing the turnout coat; tabulate thermal resistances of the layers and processes; and (b) For a prescribed radiant heat flux on the fire-side surface and temperature of $T_i = 60^\circ\text{C}$ at the inner surface, calculate the fire-side surface temperature, T_o .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction through the layers, (3) Heat is transferred by conduction and radiation exchange across the stagnant air gaps, (3) Constant properties.

PROPERTIES: Table A-4, Air (470 K, 1 atm): $k_{ab} = k_{cd} = 0.0387 \text{ W/m-K}$.

ANALYSIS: (a) The thermal circuit is shown with labels for the temperatures and thermal resistances.

The conduction thermal resistances have the form $R_{cd}'' = L/k$ while the radiation thermal resistances across the air gaps have the form

$$R_{\text{rad}}'' = \frac{1}{h_{\text{rad}}} = \frac{1}{4\sigma T_{\text{avg}}^3}$$

The linearized radiation coefficient follows from Eqs. 1.8 and 1.9 with $\epsilon = 1$ where T_{avg} represents the average temperature of the surfaces comprising the gap

$$h_{\text{rad}} = \sigma (T_1 + T_2) (T_1^2 + T_2^2) \approx 4\sigma T_{\text{avg}}^3$$

For the radiation thermal resistances tabulated below, we used $T_{\text{avg}} = 470 \text{ K}$.

Continued

PROBLEM 3.19 (Cont.)

	Shell (s)	Air gap (a-b)	Barrier (mb)	Air gap (c-d)	Liner (tl)	Total (tot)
$R''_{cd} \left(m^2 \cdot K / W \right)$	0.01702	0.0259	0.04583	0.0259	0.00921	--
$R''_{rad} \left(m^2 \cdot K / W \right)$	--	0.04246	--	0.04246	--	--
$R''_{gap} \left(m^2 \cdot K / W \right)$	--	0.01611	--	0.01611	--	--
R''_{total}	--	--	--	--	--	0.1043

From the thermal circuit, the resistance across the gap for the conduction and radiation processes is

$$\frac{1}{R''_{gap}} = \frac{1}{R''_{cd}} + \frac{1}{R''_{rad}}$$

and the total thermal resistance of the turn coat is

$$R''_{tot} = R''_{cd,s} + R''_{gap,a-b} + R''_{cd,mb} + R''_{gap,c-d} + R''_{cd,tl}$$

(b) If the heat flux through the coat is 0.25 W/cm^2 , the fire-side surface temperature T_o can be calculated from the rate equation written in terms of the overall thermal resistance.

$$q'' = (T_o - T_i) / R''_{tot}$$

$$T_o = 66^\circ\text{C} + 0.25 \text{ W/cm}^2 \times \left(10^2 \text{ cm/m} \right)^2 \times 0.1043 \text{ m}^2 \cdot \text{K/W}$$

$$T_o = 327^\circ\text{C}$$

COMMENTS: (1) From the tabulated results, note that the thermal resistance of the moisture barrier (mb) is nearly 3 times larger than that for the shell or air gap layers, and 4.5 times larger than the thermal liner layer.

(2) The air gap conduction and radiation resistances were calculated based upon the average temperature of 470 K. This value was determined by setting $T_{avg} = (T_o + T_i)/2$ and solving the equation set using *IHT* with $k_{air} = k_{air}(T_{avg})$.

PROBLEM 3.20

KNOWN: Materials and dimensions of a composite wall separating a combustion gas from a liquid coolant.

FIND: (a) Heat loss per unit area, and (b) Temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Constant properties, (4) Negligible radiation effects.

PROPERTIES: Table A-1, St. St. (304) ($\bar{T} \approx 1000\text{K}$): $k = 25.4 \text{ W/m}\cdot\text{K}$; Table A-2, Beryllium Oxide ($T \approx 1500\text{K}$): $k = 21.5 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) The desired heat flux may be expressed as

$$q'' = \frac{T_{\infty,1} - T_{\infty,2}}{\frac{1}{h_1} + \frac{L_A}{k_A} + R_{t,c} + \frac{L_B}{k_B} + \frac{1}{h_2}} = \frac{(2600 - 100)^\circ\text{C}}{\left[\frac{1}{50} + \frac{0.01}{21.5} + 0.05 + \frac{0.02}{25.4} + \frac{1}{1000} \right] \frac{\text{m}^2\cdot\text{K}}{\text{W}}}$$

$$q'' = 34,600 \text{ W/m}^2.$$

(b) The composite surface temperatures may be obtained by applying appropriate rate equations. From the fact that $q'' = h_1 (T_{\infty,1} - T_{s,1})$, it follows that

$$T_{s,1} = T_{\infty,1} - \frac{q''}{h_1} = 2600^\circ\text{C} - \frac{34,600 \text{ W/m}^2}{50 \text{ W/m}^2\cdot\text{K}} = 1908^\circ\text{C}.$$

With $q'' = (k_A / L_A)(T_{s,1} - T_{c,1})$, it also follows that

$$T_{c,1} = T_{s,1} - \frac{L_A q''}{k_A} = 1908^\circ\text{C} - \frac{0.01\text{m} \times 34,600 \text{ W/m}^2}{21.5 \text{ W/m}\cdot\text{K}} = 1892^\circ\text{C}.$$

Similarly, with $q'' = (T_{c,1} - T_{c,2}) / R_{t,c}$

$$T_{c,2} = T_{c,1} - R_{t,c} q'' = 1892^\circ\text{C} - 0.05 \frac{\text{m}^2\cdot\text{K}}{\text{W}} \times 34,600 \frac{\text{W}}{\text{m}^2} = 162^\circ\text{C}$$

Continued

PROBLEM 3.20 (Cont.)

and with $q'' = (k_B / L_B)(T_{c,2} - T_{s,2})$,

$$T_{s,2} = T_{c,2} - \frac{L_B q''}{k_B} = 162^\circ\text{C} - \frac{0.02\text{m} \times 34,600\text{ W/m}^2}{25.4\text{ W/m}\cdot\text{K}} = 134.6^\circ\text{C}.$$

The temperature distribution is therefore of the following form:

COMMENTS: (1) The calculations may be checked by recomputing q'' from

$$q'' = h_2 (T_{s,2} - T_{\infty,2}) = 1000\text{ W/m}^2 \cdot \text{K} (134.6 - 100)^\circ\text{C} = 34,600\text{ W/m}^2$$

(2) The initial *estimates* of the mean material temperatures are in error, particularly for the stainless steel. For improved accuracy the calculations should be repeated using k values corresponding to $T \approx 1900^\circ\text{C}$ for the oxide and $T \approx 115^\circ\text{C}$ for the steel.

(3) The major contributions to the total resistance are made by the combustion gas boundary layer and the contact, where the temperature drops are largest.

PROBLEM 3.21

KNOWN: Thickness, overall temperature difference, and pressure for two stainless steel plates.

FIND: (a) Heat flux and (b) Contact plane temperature drop.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Constant properties.

PROPERTIES: Table A-1, Stainless Steel ($T \approx 400\text{K}$): $k = 16.6 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) With $R''_{t,c} \approx 15 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}$ from Table 3.1 and

$$\frac{L}{k} = \frac{0.01\text{m}}{16.6 \text{ W/m}\cdot\text{K}} = 6.02 \times 10^{-4} \text{ m}^2 \cdot \text{K/W},$$

it follows that

$$R''_{\text{tot}} = 2(L/k) + R''_{t,c} \approx 27 \times 10^{-4} \text{ m}^2 \cdot \text{K/W};$$

hence

$$q'' = \frac{\Delta T}{R''_{\text{tot}}} = \frac{100^\circ\text{C}}{27 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}} = 3.70 \times 10^4 \text{ W/m}^2.$$

(b) From the thermal circuit,

$$\frac{\Delta T_c}{T_{s,1} - T_{s,2}} = \frac{R''_{t,c}}{R''_{\text{tot}}} = \frac{15 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}}{27 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}} = 0.556.$$

Hence,

$$\Delta T_c = 0.556(T_{s,1} - T_{s,2}) = 0.556(100^\circ\text{C}) = 55.6^\circ\text{C}.$$

COMMENTS: The contact resistance is significant relative to the conduction resistances. The value of $R''_{t,c}$ would diminish, however, with increasing pressure. Note that there is considerable uncertainty in the answer since the thermal contact resistance can take on a wide range of values.

PROBLEM 3.22

KNOWN: Temperatures and convection coefficients associated with fluids at inner and outer surfaces of a composite wall. Contact resistance, dimensions, and thermal conductivities associated with wall materials.

FIND: (a) Rate of heat transfer through the wall, (b) Temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Negligible radiation, (4) Constant properties.

ANALYSIS: (a) Calculate the total resistance to find the heat rate,

$$R_{\text{tot}} = \frac{1}{h_1 A} + \frac{L_A}{k_A A} + R_{t,c} + \frac{L_B}{k_B A} + \frac{1}{h_2 A}$$

$$R_{\text{tot}} = \left[\frac{1}{10 \times 5} + \frac{0.01}{0.1 \times 5} + \frac{0.3}{5} + \frac{0.02}{0.04 \times 5} + \frac{1}{20 \times 5} \right] \frac{\text{K}}{\text{W}}$$

$$R_{\text{tot}} = [0.02 + 0.02 + 0.06 + 0.10 + 0.01] \frac{\text{K}}{\text{W}} = 0.21 \frac{\text{K}}{\text{W}}$$

$$q = \frac{T_{\infty,1} - T_{\infty,2}}{R_{\text{tot}}} = \frac{(200 - 40)^\circ \text{C}}{0.21 \text{ K/W}} = 762 \text{ W.}$$

(b) It follows that

$$T_{s,1} = T_{\infty,1} - \frac{q}{h_1 A} = 200^\circ \text{C} - \frac{762 \text{ W}}{50 \text{ W/K}} = 184.8^\circ \text{C}$$

$$T_A = T_{s,1} - \frac{q L_A}{k_A A} = 184.8^\circ \text{C} - \frac{762 \text{ W} \times 0.01 \text{ m}}{0.1 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 5 \text{ m}^2} = 169.6^\circ \text{C}$$

$$T_B = T_A - q R_{t,c} = 169.6^\circ \text{C} - 762 \text{ W} \times 0.06 \frac{\text{K}}{\text{W}} = 123.8^\circ \text{C}$$

$$T_{s,2} = T_B - \frac{q L_B}{k_B A} = 123.8^\circ \text{C} - \frac{762 \text{ W} \times 0.02 \text{ m}}{0.04 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 5 \text{ m}^2} = 47.6^\circ \text{C}$$

$$T_{\infty,2} = T_{s,2} - \frac{q}{h_2 A} = 47.6^\circ \text{C} - \frac{762 \text{ W}}{100 \text{ W/K}} = 40^\circ \text{C}$$

PROBLEM 3.23

KNOWN: Outer and inner surface convection conditions associated with zirconia-coated, Inconel turbine blade. Thicknesses, thermal conductivities, and interfacial resistance of the blade materials. Maximum allowable temperature of Inconel.

FIND: Whether blade operates below maximum temperature. Temperature distribution in blade, with and without the TBC.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction in a composite plane wall, (2) Constant properties, (3) Negligible radiation.

ANALYSIS: For a unit area, the total thermal resistance with the TBC is

$$R''_{\text{tot},w} = h_o^{-1} + (L/k)_{Zr} + R''_{t,c} + (L/k)_{In} + h_i^{-1}$$

$$R''_{\text{tot},w} = \left(10^{-3} + 3.85 \times 10^{-4} + 10^{-4} + 2 \times 10^{-4} + 2 \times 10^{-3} \right) \text{m}^2 \cdot \text{K/W} = 3.69 \times 10^{-3} \text{m}^2 \cdot \text{K/W}$$

With a heat flux of

$$q''_w = \frac{T_{\infty,o} - T_{\infty,i}}{R''_{\text{tot},w}} = \frac{1300 \text{ K}}{3.69 \times 10^{-3} \text{m}^2 \cdot \text{K/W}} = 3.52 \times 10^5 \text{ W/m}^2$$

the inner and outer surface temperatures of the Inconel are

$$T_{s,i(w)} = T_{\infty,i} + (q''_w / h_i) = 400 \text{ K} + \left(3.52 \times 10^5 \text{ W/m}^2 / 500 \text{ W/m}^2 \cdot \text{K} \right) = 1104 \text{ K}$$

$$T_{s,o(w)} = T_{\infty,i} + \left[(1/h_i) + (L/k)_{In} \right] q''_w = 400 \text{ K} + \left(2 \times 10^{-3} + 2 \times 10^{-4} \right) \text{m}^2 \cdot \text{K/W} \left(3.52 \times 10^5 \text{ W/m}^2 \right) = 1174 \text{ K}$$

Without the TBC, $R''_{\text{tot},wo} = h_o^{-1} + (L/k)_{In} + h_i^{-1} = 3.20 \times 10^{-3} \text{m}^2 \cdot \text{K/W}$, and $q''_{wo} = (T_{\infty,o} - T_{\infty,i}) / R''_{\text{tot},wo} = (1300 \text{ K}) / 3.20 \times 10^{-3} \text{m}^2 \cdot \text{K/W} = 4.06 \times 10^5 \text{ W/m}^2$. The inner and outer surface temperatures of the Inconel are then

$$T_{s,i(wo)} = T_{\infty,i} + (q''_{wo} / h_i) = 400 \text{ K} + \left(4.06 \times 10^5 \text{ W/m}^2 / 500 \text{ W/m}^2 \cdot \text{K} \right) = 1212 \text{ K}$$

$$T_{s,o(wo)} = T_{\infty,i} + \left[(1/h_i) + (L/k)_{In} \right] q''_{wo} = 400 \text{ K} + \left(2 \times 10^{-3} + 2 \times 10^{-4} \right) \text{m}^2 \cdot \text{K/W} \left(4.06 \times 10^5 \text{ W/m}^2 \right) = 1293 \text{ K}$$

Continued...

PROBLEM 3.23 (Cont.)

Use of the TBC facilitates operation of the Inconel below $T_{\max} = 1250$ K.

COMMENTS: Since the durability of the TBC decreases with increasing temperature, which increases with increasing thickness, limits to the thickness are associated with reliability considerations.

PROBLEM 3.24

KNOWN: Size and surface temperatures of a cubical freezer. Materials, thicknesses and interface resistances of freezer wall.

FIND: Cooling load.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Constant properties.

PROPERTIES: Table A-1, Aluminum 2024 (~267K): $k_{al} = 173 \text{ W/m}\cdot\text{K}$. Table A-1, Carbon steel AISI 1010 (~295K): $k_{st} = 64 \text{ W/m}\cdot\text{K}$. Table A-3 (~300K): $k_{ins} = 0.039 \text{ W/m}\cdot\text{K}$.

ANALYSIS: For a unit wall surface area, the total thermal resistance of the composite wall is

$$R''_{tot} = \frac{L_{al}}{k_{al}} + R''_{t,c} + \frac{L_{ins}}{k_{ins}} + R''_{t,c} + \frac{L_{st}}{k_{st}}$$

$$R''_{tot} = \frac{0.00635\text{m}}{173 \text{ W/m}\cdot\text{K}} + 2.5 \times 10^{-4} \frac{\text{m}^2 \cdot \text{K}}{\text{W}} + \frac{0.100\text{m}}{0.039 \text{ W/m}\cdot\text{K}} + 2.5 \times 10^{-4} \frac{\text{m}^2 \cdot \text{K}}{\text{W}} + \frac{0.00635\text{m}}{64 \text{ W/m}\cdot\text{K}}$$

$$R''_{tot} = \left(3.7 \times 10^{-5} + 2.5 \times 10^{-4} + 2.56 + 2.5 \times 10^{-4} + 9.9 \times 10^{-5} \right) \text{m}^2 \cdot \text{K} / \text{W} = 2.56 \text{ m}^2 \cdot \text{K} / \text{W}$$

Hence, the heat flux is

$$q'' = \frac{T_{s,o} - T_{s,i}}{R''_{tot}} = \frac{[22 - (-6)]^\circ\text{C}}{2.56 \text{ m}^2 \cdot \text{K} / \text{W}} = 10.9 \frac{\text{W}}{\text{m}^2}$$

and the cooling load is

$$q = A_S q'' = 6 \text{ W}^2 q'' = 54 \text{m}^2 \times 10.9 \text{ W/m}^2 = 590 \text{ W} \quad <$$

COMMENT: Thermal resistances associated with the cladding and the adhesive joints are negligible compared to that of the insulation.

PROBLEM 3.25

KNOWN: Operating conditions, measured temperatures and heat input, and theoretical thermal conductivity of a carbon nanotube.

FIND: (a) Thermal contact resistance between the carbon nanotube and the heating and sensing islands, (b) Fraction of total thermal resistance between the heating and sensing islands due to thermal contact resistance for $5 \mu\text{m} \leq s \leq 20 \mu\text{m}$.

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Isothermal heating and sensing islands, (5) Negligible radiation and convection heat transfer.

PROPERTIES: $k_{\text{cn,T}} = 5000 \text{ W/m}\cdot\text{K}$

ANALYSIS:

(a) The total thermal resistance between the heated and sensing island is

$$R_{\text{t,tot}} = \frac{s}{k_{\text{cn,T}}A_{\text{cn}}} + 2R_{\text{t,c}}$$

The value of this total resistance is the same as the one posed in Example 3.3 with $k_{\text{cn}} = 3113 \text{ W/m}\cdot\text{K}$ and $R_{\text{t,c}} = 0$ or

$$\frac{s}{k_{\text{cn,T}}A_{\text{cn}}} + 2R_{\text{t,c}} = \frac{s}{k_{\text{cn}}A_{\text{cn}}}$$

for which

$$\begin{aligned} R_{\text{t,c}} &= \frac{s}{2A_{\text{cn}}} \left[\frac{1}{k_{\text{cn}}} - \frac{1}{k_{\text{cn,T}}} \right] = \frac{5 \times 10^{-6} \text{ m}}{2 \times 1.54 \times 10^{-16} \text{ m}^2} \times \left[\frac{1}{3113 \text{ W/m}\cdot\text{K}} - \frac{1}{5000 \text{ W/m}\cdot\text{K}} \right] \\ &= 1.97 \times 10^6 \text{ K/W} \end{aligned}$$

(b) The fraction of the total resistance due to the thermal contact resistance is

$$f = \frac{2R_{\text{t,c}}}{2R_{\text{t,c}} + \left[\frac{s}{k_{\text{cn,T}}A_{\text{cn}}} \right]} = \frac{2 \times 1.97 \times 10^6 \text{ K/W}}{2 \times 1.97 \times 10^6 \text{ K/W} + \left[\frac{s}{5000 \text{ W/m}\cdot\text{K} \times 1.54 \times 10^{-16} \text{ m}^2} \right]}$$

As evident in the plot below, the fraction of the total thermal resistance due to thermal contact decreases from 0.38 at $s = 5 \mu\text{m}$ to 0.13 at $s = 20 \mu\text{m}$.

Continued...

PROBLEM 3.25 (Cont.)

COMMENT: To desensitize the experiment to uncertainty due to the unknown thermal contact resistance values, a large separation distance between the islands is desired. As the separation distance becomes large, however, the surface area of the carbon nanotube increases and surface heat losses by radiation may invalidate the assumption of a linear temperature distribution along the length of the nanotube. An optimal separation distance exists that will minimize the undesirable effects of the thermal contact resistances and radiation loss from the surface of the nanotube.

PROBLEM 3.26

KNOWN: Geometry of two mating surfaces.

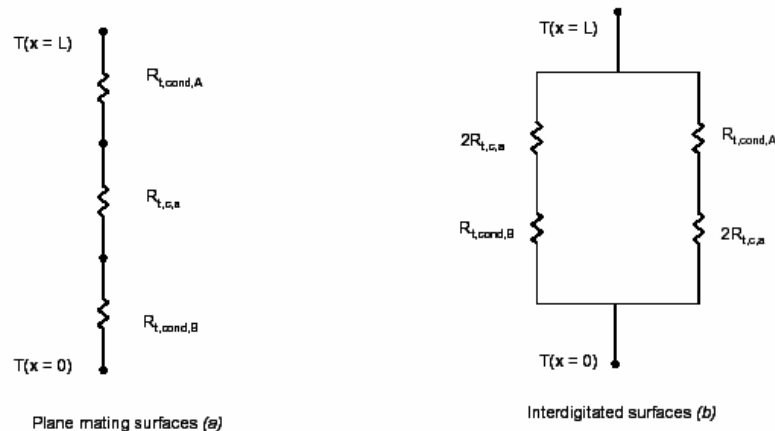

FIND: Possible reduction in contact resistance associated with grooving the surfaces.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Steady-state conditions, (3) One-dimensional heat transfer, (4) Contact resistance is the same in schematics (a) and (b).

ANALYSIS: For the plane mating surfaces of configuration (a), the thermal resistance network between $x = 0$ and $x = L$ is shown on the left below.

Here, $R_{t,c,a}$ is the contact resistance for configuration (a). For a width of $2w = w_a + w_b$ and for unit depth into the page, the conduction resistances for configuration (a) are

$$R_{t,cond,A} = \frac{L/2}{2k_A w}; \quad R_{t,cond,B} = \frac{L/2}{2k_B w}$$

$$\text{Therefore, } R_{tot,a} = \frac{L}{4w} \left[\frac{1}{k_A} + \frac{1}{k_B} \right] + R_{t,c,a} \quad (1)$$

Continued...

PROBLEM 3.26 (Cont.)

For configuration b (shown on the right in the sketch above), the thermal resistance network between $x = 0$ and $x = L$ for a width $2w = w_a + w_b$ and unit depth into the page,

$$R_{t,\text{cond},A} = \frac{L}{k_A w}; \quad R_{t,\text{cond},B} = \frac{L}{k_B w}$$

The contact resistance associated with width w ($R_{t,c,a}$) is twice that associated with width $2w$ ($R_{t,c,b} = 2R_{t,c,a}$). Therefore,

$$\frac{1}{R_{\text{tot},b}} = \frac{1}{\frac{L}{k_A w} + 2R_{t,c,a}} + \frac{1}{\frac{L}{k_B w} + 2R_{t,c,a}} \quad (2)$$

Hence,

$$\frac{R_{\text{tot},a}}{R_{\text{tot},b}} = \frac{\frac{L}{4w} \left[\frac{1}{k_A} + \frac{1}{k_B} \right] + R_{t,c,a}}{\frac{L}{k_A w} + 2R_{t,c,a}} + \frac{\frac{L}{4w} \left[\frac{1}{k_A} + \frac{1}{k_B} \right] + R_{t,c,a}}{\frac{L}{k_B w} + 2R_{t,c,a}}$$

For the limiting case of $R_{t,c,a} = 0$, the preceding expression reduces to

$$\frac{R_{\text{tot},a}}{R_{\text{tot},b}} = \frac{1}{4} [k_A + k_B] \cdot \left[\frac{1}{k_A} + \frac{1}{k_B} \right]$$

For the case $L/w = 1$, the preceding expression reduces to

$$\frac{R_{\text{tot},a}}{R_{\text{tot},b}} = \frac{\frac{1}{4} \left[\frac{1}{k_A} + \frac{1}{k_B} \right] + R_{t,c,a}}{\frac{1}{k_A} + 2R_{t,c,a}} + \frac{\frac{1}{4} \left[\frac{1}{k_A} + \frac{1}{k_B} \right] + R_{t,c,a}}{\frac{1}{k_B} + 2R_{t,c,a}} \quad (3)$$

The ratio of the total thermal resistance of (a) relative to that of (b) is shown for $R_{t,c,a} = 0$ K/(W/m) and 1000 K/(W/m), $k_A = 10$ W/m·K, $1 \leq k_B \leq 100$ W/m·K and $L/w = 1$. The scheme reduces the *total* thermal resistance when the contact resistance is negligible, but is ineffective when the contact resistance is large. The total resistance always increases with increasing contact resistance.

PROBLEM 3.27

KNOWN: Operating conditions for a board mounted chip.

FIND: (a) Equivalent thermal circuit, (b) Chip temperature, (c) Maximum allowable heat dissipation for dielectric liquid ($h_o = 1000 \text{ W/m}^2\cdot\text{K}$) and air ($h_o = 100 \text{ W/m}^2\cdot\text{K}$). Effect of changes in circuit board temperature and contact resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible chip thermal resistance, (4) Negligible radiation, (5) Constant properties.

PROPERTIES: Table A-2, Aluminum oxide (polycrystalline, 358 K): $k_b = 32.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a)

(b) Applying conservation of energy to a control surface about the chip ($\dot{E}_{in} - \dot{E}_{out} = 0$),

$$q''_c - q''_i - q''_o = 0$$

$$q''_c = \frac{T_c - T_{\infty,i}}{1/h_i + (L/k)_b + R''_{t,c}} + \frac{T_c - T_{\infty,o}}{1/h_o}$$

With $q''_c = 3 \times 10^4 \text{ W/m}^2$, $h_o = 1000 \text{ W/m}^2\cdot\text{K}$, $k_b = 1 \text{ W/m}\cdot\text{K}$ and $R''_{t,c} = 10^{-4} \text{ m}^2 \cdot \text{K/W}$,

$$3 \times 10^4 \text{ W/m}^2 = \frac{T_c - 20^\circ\text{C}}{\left(1/40 + 0.005/1 + 10^{-4}\right) \text{ m}^2 \cdot \text{K/W}} + \frac{T_c - 20^\circ\text{C}}{(1/1000) \text{ m}^2 \cdot \text{K/W}}$$

$$3 \times 10^4 \text{ W/m}^2 = (33.2T_c - 664 + 1000T_c - 20,000) \text{ W/m}^2 \cdot \text{K}$$

$$1033T_c = 50,664$$

$$T_c = 49^\circ\text{C}.$$

(c) For $T_c = 85^\circ\text{C}$ and $h_o = 1000 \text{ W/m}^2\cdot\text{K}$, the foregoing energy balance yields

$$q''_c = 67,160 \text{ W/m}^2$$

with $q''_o = 65,000 \text{ W/m}^2$ and $q''_i = 2160 \text{ W/m}^2$. Replacing the dielectric with air ($h_o = 100 \text{ W/m}^2\cdot\text{K}$), the following results are obtained for different combinations of k_b and $R''_{t,c}$.

Continued...

PROBLEM 3.27 (Cont.)

k_b (W/m·K)	$R_{t,c}''$ (m ² ·K/W)	q_i'' (W/m ²)	q_o'' (W/m ²)	q_c'' (W/m ²)
1	10 ⁻⁴	2159	6500	8659
32.4	10 ⁻⁴	2574	6500	9074
1	10 ⁻⁵	2166	6500	8666
32.4	10 ⁻⁵	2583	6500	9083

<

COMMENTS: 1. For the conditions of part (b), the total internal resistance is 0.0301 m²·K/W, while the outer resistance is 0.001 m²·K/W. Hence

$$\frac{q_o''}{q_i''} = \frac{(T_c - T_{\infty,o})/R_o''}{(T_c - T_{\infty,i})/R_i''} = \frac{0.0301}{0.001} = 30.$$

and only approximately 3% of the heat is dissipated through the board.

2. With $h_o = 100$ W/m²·K, the outer resistance increases to 0.01 m²·K/W, in which case $q_o''/q_i'' = R_i''/R_o'' = 0.0301/0.01 = 3.1$ and now almost 25% of the heat is dissipated through the board. Hence, although measures to reduce R_i'' would have a negligible effect on q_c'' for the liquid coolant, some improvement may be gained for air-cooled conditions. As shown in the table of part (b), use of an aluminum oxide board increase q_i'' by 19% (from 2159 to 2574 W/m²) by reducing R_i'' from 0.0301 to 0.0253 m²·K/W.

Because the initial contact resistance ($R_{t,c}'' = 10^{-4}$ m²·K/W) is already much less than R_i'' , any reduction in its value would have a negligible effect on q_i'' . The largest gain would be realized by increasing h_i , since the inside convection resistance makes the dominant contribution to the total internal resistance.

PROBLEM 3.28

KNOWN: Dimensions, thermal conductivity and emissivity of base plate. Temperature and convection coefficient of adjoining air. Temperature of surroundings. Maximum allowable temperature of transistor case. Case-plate interface conditions.

FIND: (a) Maximum allowable power dissipation for an air-filled interface, (b) Effect of convection coefficient on maximum allowable power dissipation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible heat transfer from the enclosure, to the surroundings. (3) One-dimensional conduction in the base plate, (4) Radiation exchange at surface of base plate is with large surroundings, (5) Constant thermal conductivity.

PROPERTIES: Aluminum-aluminum interface, air-filled, 10 μm roughness, 10^5 N/m^2 contact pressure (Table 3.1): $R_{t,c}'' = 2.75 \times 10^{-4} \text{ m}^2 \cdot \text{K} / \text{W}$.

ANALYSIS: (a) With all of the heat dissipation transferred through the base plate,

$$P_{\text{elec}} = q = \frac{T_{s,c} - T_{\infty}}{R_{\text{tot}}} \quad (1)$$

where $R_{\text{tot}} = R_{t,c} + R_{\text{cnd}} + \left[(1/R_{\text{cnv}}) + (1/R_{\text{rad}}) \right]^{-1}$

$$R_{\text{tot}} = \frac{R_{t,c}''}{A_c} + \frac{L}{kW^2} + \frac{1}{W^2} \left(\frac{1}{h + h_r} \right) \quad (2)$$

$$\text{and} \quad h_r = \varepsilon \sigma (T_{s,p} + T_{\text{sur}}) (T_{s,p}^2 + T_{\text{sur}}^2) \quad (3)$$

To obtain $T_{s,p}$, the following energy balance must be performed on the plate surface,

$$q = \frac{T_{s,c} - T_{s,p}}{R_{t,c} + R_{\text{cnd}}} = q_{\text{cnv}} + q_{\text{rad}} = hW^2 (T_{s,p} - T_{\infty}) + h_r W^2 (T_{s,p} - T_{\text{sur}}) \quad (4)$$

With $R_{t,c} = 2.75 \times 10^{-4} \text{ m}^2 \cdot \text{K} / \text{W} / 2 \times 10^{-4} \text{ m}^2 = 1.375 \text{ K/W}$, $R_{\text{cnd}} = 0.006 \text{ m} / (240 \text{ W/m-K} \times 4 \times 10^{-4} \text{ m}^2) = 0.0625 \text{ K/W}$, and the prescribed values of h , W , $T_{\infty} = T_{\text{sur}}$ and ε , Eq. (4) yields a surface temperature of $T_{s,p} = 357.6 \text{ K} = 84.6^\circ\text{C}$ and a power dissipation of

Continued

PROBLEM 3.28 (Cont.)

$$P_{\text{elec}} = q = 0.268 \text{ W}$$

<

The convection and radiation resistances are $R_{\text{cnv}} = 625 \text{ K/W}$ and $R_{\text{rad}} = 345 \text{ K/W}$, where $h_r = 7.25 \text{ W/m}^2 \cdot \text{K}$.

(b) With the major contribution to the total resistance made by convection, significant benefit may be derived by increasing the value of h .

For $h = 200 \text{ W/m}^2 \cdot \text{K}$, $R_{\text{cnv}} = 12.5 \text{ K/W}$ and $T_{\text{s,p}} = 351.6 \text{ K}$, yielding $R_{\text{rad}} = 355 \text{ K/W}$. The effect of radiation is then negligible.

COMMENTS: (1) The plate conduction resistance is negligible, and even for $h = 200 \text{ W/m}^2 \cdot \text{K}$, the contact resistance is small relative to the convection resistance. However, $R_{\text{t,c}}$ could be rendered negligible by using indium foil, instead of an air gap, at the interface. From Table 3.1, $R_{\text{t,c}}'' = 0.07 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}$, in which case $R_{\text{t,c}} = 0.035 \text{ m}^2 \cdot \text{K/W}$.

(2) Because $A_c < W^2$, heat transfer by conduction in the plate is actually two-dimensional, rendering the conduction resistance even smaller.

PROBLEM 3.29

KNOWN: Conduction in a conical section with prescribed diameter, D , as a function of x in the form $D = ax^{1/2}$.

FIND: (a) Temperature distribution, $T(x)$, (b) Heat transfer rate, q_x .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x -direction, (3) No internal heat generation, (4) Constant properties.

PROPERTIES: Table A-1, Pure Aluminum (500K): $k = 236 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) Based upon the assumptions, and following the same methodology of Example 3.4, q_x is a constant independent of x . Accordingly,

$$q_x = -kA \frac{dT}{dx} = -k \left[\pi \left(ax^{1/2} \right)^2 / 4 \right] \frac{dT}{dx} \quad (1)$$

using $A = \pi D^2 / 4$ where $D = ax^{1/2}$. Separating variables and identifying limits,

$$\frac{4q_x}{\pi a^2 k} \int_{x_1}^x \frac{dx}{x} = - \int_{T_1}^T dT. \quad (2)$$

Integrating and solving for $T(x)$ and then for T_2 ,

$$T(x) = T_1 - \frac{4q_x}{\pi a^2 k} \ln \frac{x}{x_1} \quad T_2 = T_1 - \frac{4q_x}{\pi a^2 k} \ln \frac{x_2}{x_1}. \quad (3,4)$$

Solving Eq. (4) for q_x and then substituting into Eq. (3) gives the results,

$$q_x = -\frac{\pi a^2 k (T_1 - T_2)}{4 \ln (x_1 / x_2)} \quad (5)$$

$$T(x) = T_1 + (T_1 - T_2) \frac{\ln (x/x_1)}{\ln (x_1 / x_2)}. \quad <$$

From Eq. (1) note that $(dT/dx) \cdot x = \text{Constant}$. It follows that $T(x)$ has the distribution shown above.

(b) The heat rate follows from Eq. (5),

$$q_x = \frac{\pi}{4} \times 0.5^2 \text{ m} \times 236 \frac{\text{W}}{\text{m}\cdot\text{K}} (600 - 400) \text{ K} / \ln \frac{25}{125} = 5.76 \text{ kW}. \quad <$$

PROBLEM 3.30

KNOWN: Geometry and surface conditions of a truncated solid cone.

FIND: (a) Temperature distribution, (b) Rate of heat transfer across the cone.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x , (3) Constant properties.

PROPERTIES: Table A-1, Aluminum (333K): $k = 238 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) From Fourier's law, Eq. 2.1, with $A = \pi D^2 / 4 = (\pi a^2 / 4) x^3$, it follows that

$$\frac{4q_x dx}{\pi a^2 x^3} = -k dT.$$

Hence, since q_x is independent of x ,

$$\frac{4q_x}{\pi a^2} \int_{x_1}^x \frac{dx}{x^3} = -k \int_{T_1}^T dT$$

or

$$\frac{4q_x}{\pi a^2} \left[-\frac{1}{2x^2} \right]_{x_1}^x = -k (T - T_1).$$

Hence

$$T = T_1 + \frac{2q_x}{\pi a^2 k} \left[\frac{1}{x^2} - \frac{1}{x_1^2} \right].$$

(b) From the foregoing expression, it also follows that

$$q_x = \frac{\pi a^2 k}{2} \frac{T_2 - T_1}{\left[1/x_2^2 - 1/x_1^2 \right]}$$

$$q_x = \frac{\pi (1\text{m}^{-1}) 238 \text{ W/m}\cdot\text{K}}{2} \times \frac{(20 - 100)^\circ \text{C}}{\left[(0.225)^{-2} - (0.075)^{-2} \right] \text{m}^{-2}}$$

$$q_x = 189 \text{ W}.$$

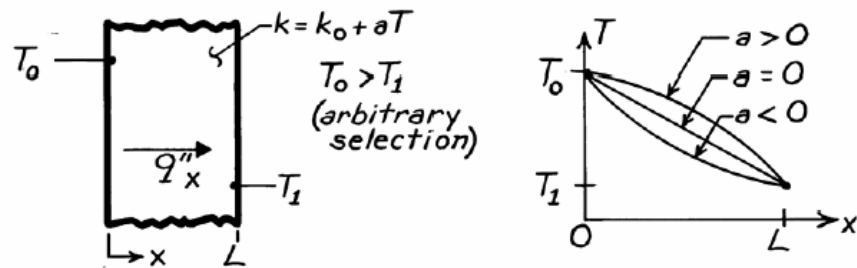

COMMENTS: The foregoing results are approximate due to use of a one-dimensional model in treating what is inherently a two-dimensional problem.

PROBLEM 3.31

KNOWN: Temperature dependence of the thermal conductivity, k .

FIND: Heat flux and form of temperature distribution for a plane wall.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction through a plane wall, (2) Steady-state conditions, (3) No internal heat generation.

ANALYSIS: For the assumed conditions, q_x and $A(x)$ are constant and Eq. 3.21 gives

$$q''_x \int_0^L dx = - \int_{T_0}^{T_1} (k_0 + aT) dT$$

$$q''_x = \frac{1}{L} \left[k_0 (T_0 - T_1) + \frac{a}{2} (T_0^2 - T_1^2) \right].$$

From Fourier's law,

$$q''_x = -(k_0 + aT) dT/dx.$$

Hence, since the product of $(k_0 + aT)$ and dT/dx is constant, decreasing T with increasing x implies,

$a > 0$: decreasing $(k_0 + aT)$ and increasing $|dT/dx|$ with increasing x

$a = 0$: $k = k_0 \Rightarrow$ constant (dT/dx)

$a < 0$: increasing $(k_0 + aT)$ and decreasing $|dT/dx|$ with increasing x .

The temperature distributions appear as shown in the above sketch.

PROBLEM 3.32

KNOWN: Temperature dependence of tube wall thermal conductivity.

FIND: Expressions for heat transfer per unit length and tube wall thermal (conduction) resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) No internal heat generation.

ANALYSIS: From Eq. 3.24, the appropriate form of Fourier's law is

$$q_r = -kA_r \frac{dT}{dr} = -k(2\pi rL) \frac{dT}{dr}$$

$$q'_r = -2\pi kr \frac{dT}{dr}$$

$$q'_r = -2\pi rk_o(1 + aT) \frac{dT}{dr}.$$

Separating variables,

$$-\frac{q'_r}{2\pi r} \frac{dr}{r} = k_o(1 + aT)dT$$

and integrating across the wall, find

$$-\frac{q'_r}{2\pi} \int_{r_i}^{r_o} \frac{dr}{r} = k_o \int_{T_i}^{T_o} (1 + aT) dT$$

$$-\frac{q'_r}{2\pi} \ln \frac{r_o}{r_i} = k_o \left[T + \frac{aT^2}{2} \right] \Big|_{T_i}^{T_o}$$

$$-\frac{q'_r}{2\pi} \ln \frac{r_o}{r_i} = k_o \left[(T_o - T_i) + \frac{a}{2} (T_o^2 - T_i^2) \right]$$

$$q'_r = -2\pi k_o \left[1 + \frac{a}{2} (T_o + T_i) \right] \frac{(T_o - T_i)}{\ln(r_o / r_i)}. \quad <$$

It follows that the overall thermal resistance per unit length is

$$R'_t = \frac{T_i - T_o}{q'_r} = \frac{\ln(r_o / r_i)}{2\pi k_o \left[1 + \frac{a}{2} (T_o + T_i) \right]}. \quad <$$

COMMENT: Note the necessity of the stated assumptions to treating q'_r as independent of r .

PROBLEM 3.33

KNOWN: Steady-state temperature distribution of convex shape for material with $k = k_o(1 + \alpha T)$ where α is a constant and the mid-point temperature is ΔT_o higher than expected for a linear temperature distribution.

FIND: Relationship to evaluate α in terms of ΔT_o and T_1, T_2 (the temperatures at the boundaries).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) No internal heat generation, (4) α is positive and constant.

ANALYSIS: At any location in the wall, Fourier's law has the form

$$q_x'' = -k_o(1 + \alpha T) \frac{dT}{dx}. \quad (1)$$

Since q_x'' is a constant, we can separate Eq. (1), identify appropriate integration limits, and integrate to obtain

$$\int_0^L q_x'' dx = - \int_{T_1}^{T_2} k_o(1 + \alpha T) dT \quad (2)$$

$$q_x'' = -\frac{k_o}{L} \left[\left(T_2 + \frac{\alpha T_2^2}{2} \right) - \left(T_1 + \frac{\alpha T_1^2}{2} \right) \right]. \quad (3)$$

We could perform the same integration, but with the upper limits at $x = L/2$, to obtain

$$q_x'' = -\frac{2k_o}{L} \left[\left(T_{L/2} + \frac{\alpha T_{L/2}^2}{2} \right) - \left(T_1 + \frac{\alpha T_1^2}{2} \right) \right] \quad (4)$$

where

$$T_{L/2} = T(L/2) = \frac{T_1 + T_2}{2} + \Delta T_o. \quad (5)$$

Setting Eq. (3) equal to Eq. (4), substituting from Eq. (5) for $T_{L/2}$, and solving for α , it follows that

$$\alpha = \frac{2\Delta T_o}{\left(T_2^2 + T_1^2 \right)/2 - \left[(T_1 + T_2)/2 + \Delta T_o \right]^2}. <$$

PROBLEM 3.34

KNOWN: Construction and dimensions of a device to measure the temperature of a surface. Ambient and sensing temperatures, and thermal resistance between the sensing element and the pivot point.

FIND: (a) Thermal resistance between the surface temperature and the sensing temperature, (b) Surface temperature for $T_{\text{sen}} = 28.5^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Negligible nanoscale effects, (4) Constant properties.

PROPERTIES: Table A.2, polycrystalline silicon dioxide (300 K): $k = 1.38 \text{ W/m}\cdot\text{K}$. Table A.4, air (300 K): $k = 0.0263 \text{ W/m}\cdot\text{K}$.

ANALYSIS:

(a) At any x location, heat transfer in the x -direction occurs by conduction in the air as well as conduction in the probe. Applying Fourier's law,

$$q_x = -k_a A_a \frac{dT}{dx} - k_p A_p \frac{dT}{dx} \quad (1)$$

Since the probe radius is $r = Dx/2L$, the probe area is

$$A_p = \frac{\pi D^2}{4L^2} x^2 \quad \text{and} \quad A_a = \frac{\pi D^2}{4} - A_p = \frac{\pi D^2}{4} \left[1 - \frac{x^2}{L^2} \right] \quad (2a, 2b)$$

Substituting Eqs. (2a) and (2b) into Eq. (1) yields

$$q_x = -\frac{\pi D^2}{4L^2} \left[k_a (L^2 - x^2) + k_p x^2 \right] \frac{dT}{dx}$$

Separating variables and integrating,

Continued...

PROBLEM 3.34 (Cont.)

$$q_x \int_{x=0}^L \frac{dx}{k_a(L^2 - x^2) + k_p x^2} = - \frac{\pi D^2}{4L^2} \int_{T=T_{\text{surf}}}^{T_{\text{sen}}} dT = - \frac{\pi D^2}{4L^2} (T_{\text{sen}} - T_{\text{surf}})$$

Therefore, the thermal resistance associated with the probe is

$$R_{\text{sen}} = \frac{(T_{\text{surf}} - T_{\text{sen}})}{q_x} = \frac{4L^2}{\pi D^2} \int_{x=0}^L \frac{dx}{k_a L^2 + (k_p - k_a)x^2}$$

Carrying out the integration yields

$$R_{\text{sen}} = \frac{4L^2}{\pi D^2} \frac{1}{\sqrt{k_a(k_p - k_a)}} \tan^{-1} \sqrt{\frac{k_p - k_a}{k_a}}$$

Substituting values gives

$$R_{\text{sen}} = \frac{4 \times 50 \times 10^{-9} \text{ m}}{\pi \times (100 \times 10^{-9} \text{ m})^2} \times \frac{1}{\sqrt{0.0263 \text{ W/m} \cdot \text{K} \times (1.38 - 0.0263) \text{ W/m} \cdot \text{K}}} \\ \times \tan^{-1} \sqrt{\frac{(1.38 - 0.0263) \text{ W/m} \cdot \text{K}}{0.0263 \text{ W/m} \cdot \text{K}}} = 48.3 \times 10^6 \text{ K/W}$$

<

(b) The thermal circuit is

Hence,

$$\frac{(T_{\text{surf}} - T_{\text{sen}})}{R_{\text{sen}}} = \frac{(T_{\text{sen}} - T_{\infty})}{R_T}$$

$$T_{\text{surf}} = (T_{\text{sen}} - T_{\infty}) \frac{R_{\text{sen}}}{R_T} + T_{\text{sen}} = (28.5 - 25)^\circ\text{C} \times \frac{48.3 \times 10^6 \text{ K/W}}{5 \times 10^6 \text{ K/W}} + 28.5^\circ\text{C}$$

$$T_{\text{surf}} = 62.3^\circ\text{C}$$

<

COMMENT: Heat transfer within the probe region will not be one-dimensional and modification of heat transfer due to nanoscale effects may be important. However, the probe may be calibrated by measuring the surface temperature of a large isothermal object.

PROBLEM 3.35

KNOWN: Thickness and inner surface temperature of calcium silicate insulation on a steam pipe. Convection and radiation conditions at outer surface.

FIND: (a) Heat loss per unit pipe length for prescribed insulation thickness and outer surface temperature. (b) Heat loss and radial temperature distribution as a function of insulation thickness.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties.

PROPERTIES: Table A-3, Calcium Silicate ($T = 645 \text{ K}$): $k = 0.089 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) From Eq. 3.27 with $T_{s,2} = 490 \text{ K}$, the heat rate per unit length is

$$q' = q_r/L = \frac{2\pi k (T_{s,1} - T_{s,2})}{\ln(r_2/r_1)}$$

$$q' = \frac{2\pi (0.089 \text{ W/m}\cdot\text{K})(800 - 490) \text{ K}}{\ln(0.08 \text{ m}/0.06 \text{ m})}$$

$$q' = 603 \text{ W/m}.$$

(b) Performing an energy balance for a control surface around the outer surface of the insulation, it follows that

$$q'_{\text{cond}} = q'_{\text{conv}} + q'_{\text{rad}}$$

$$\frac{T_{s,1} - T_{s,2}}{\ln(r_2/r_1)/2\pi k} = \frac{T_{s,2} - T_{\infty}}{1/(2\pi r_2 h)} + \frac{T_{s,2} - T_{\text{sur}}}{1/(2\pi r_2 h_r)}$$

where $h_r = \varepsilon \sigma (T_{s,2} + T_{\text{sur}})(T_{s,2}^2 + T_{\text{sur}}^2)$. Solving this equation for $T_{s,2}$, the heat rate may be determined from

$$q' = 2\pi r_2 \left[h(T_{s,2} - T_{\infty}) + h_r(T_{s,2} - T_{\text{sur}}) \right]$$

Continued...

PROBLEM 3.35 (Cont.)

and from Eq. 3.26 the temperature distribution is

$$T(r) = \frac{T_{s,1} - T_{s,2}}{\ln(r_1/r_2)} \ln\left(\frac{r}{r_2}\right) + T_{s,2}$$

As shown below, the outer surface temperature of the insulation $T_{s,2}$ and the heat loss q' decay precipitously with increasing insulation thickness from values of $T_{s,2} = T_{s,1} = 800$ K and $q' = 11,600$ W/m, respectively, at $r_2 = r_1$ (no insulation).

When plotted as a function of a dimensionless radius, $(r - r_1)/(r_2 - r_1)$, the temperature decay becomes more pronounced with increasing r_2 .

Note that $T(r_2) = T_{s,2}$ increases with decreasing r_2 and a linear temperature distribution is approached as r_2 approaches r_1 .

COMMENTS: An insulation layer thickness of 20 mm is sufficient to maintain the outer surface temperature and heat rate below 350 K and 1000 W/m, respectively.

PROBLEM 3.36

KNOWN: Temperature and volume of hot water heater. Nature of heater insulating material. Ambient air temperature and convection coefficient. Unit cost of electric power.

FIND: Heater dimensions and insulation thickness for which annual cost of heat loss is less than \$50.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction through side and end walls, (2) Conduction resistance dominated by insulation, (3) Inner surface temperature is approximately that of the water ($T_{s,1} = 55^\circ\text{C}$), (4) Constant properties, (5) Negligible radiation due to low emissivity foil covering on insulation.

PROPERTIES: Table A.3, Urethane Foam ($T = 300\text{ K}$): $k = 0.026\text{ W/m}\cdot\text{K}$.

ANALYSIS: To minimize heat loss, tank dimensions which minimize the total surface area, $A_{s,t}$, should be selected. With $L = 4\sqrt[3]{\pi D^2}$, $A_{s,t} = \pi DL + 2\left(\pi D^2/4\right) = 4\sqrt[3]{D} + \pi D^2/2$, and the tank diameter for which $A_{s,t}$ is an extremum is determined from the requirement

$$dA_{s,t}/dD = -4\sqrt[3]{D} + \pi D = 0$$

It follows that

$$D = (4\sqrt[3]{\pi})^{1/3} \quad \text{and} \quad L = (4\sqrt[3]{\pi})^{1/3}$$

With $d^2A_{s,t}/dD^2 = 8\sqrt[3]{D} + \pi > 0$, the foregoing conditions yield the desired minimum in $A_{s,t}$. Hence, for $\forall = 100\text{ gal} \times 0.00379\text{ m}^3/\text{gal} = 0.379\text{ m}^3$,

$$D_{\text{op}} = L_{\text{op}} = 0.784\text{ m}$$

For an annual cost of heat loss of \$50 and a unit electric power cost of \$0.08/kWh

$$Q_{\text{annual}} = \$50.00/\$0.08/\text{kWh} = 625\text{ kWh}$$

The energy loss rate is therefore

$$\dot{q} = Q_{\text{annual}}/(\text{hours per year}) = 625 \times 10^3\text{ W}\cdot\text{h}/[(365\text{ days})(24\text{ h/day})] = 71.3\text{ W}$$

Continued...

PROBLEM 3.36 (Cont.)

The total heat loss through the side and end walls is

$$q = \frac{T_{s,1} - T_{\infty}}{\frac{\ln(r_2/r_1)}{2\pi k L_{op}} + \frac{1}{h 2\pi r_2 L_{op}}} + \frac{2(T_{s,1} - T_{\infty})}{\frac{\delta}{k(\pi D_{op}^2/4)} + \frac{1}{h(\pi D_{op}^2/4)}}$$

With $r_1 = D_{op}/2 = 0.392$ m and $r_2 = r_1 + \delta$, everything is known except for the insulation thickness, δ .

$$q = 71.3 \text{ W} = \frac{(55 - 20)^{\circ}\text{C}}{\frac{\ln((0.392 + \delta)/0.392)}{2\pi(0.026 \text{ W/m}\cdot\text{K})0.784 \text{ m}} + \frac{1}{(2 \text{ W/m}^2\cdot\text{K})2\pi(0.392 \text{ m} + \delta)0.784 \text{ m}}} + \frac{2(55 - 20)^{\circ}\text{C}}{\frac{\delta}{(0.026 \text{ W/m}\cdot\text{K})\pi(0.784 \text{ m})^2/4} + \frac{1}{(2 \text{ W/m}^2\cdot\text{K})\pi(0.784 \text{ m})^2/4}}$$

Solving by trial and error yields an insulation thickness of

$$\delta = 25 \text{ mm}$$

<

COMMENTS: Cylindrical containers of aspect ratio $L/D = 1$ are seldom used because of floor space constraints. Choosing $L/D = 2$, $\forall = \pi D^3/2$ and $D = (2\forall/\pi)^{1/3} = 0.623$ m. Hence, $L = 1.245$ m, $r_1 = 0.312$ m and $r_2 = 0.337$ m. It follows that $q = 76.1$ W and $C = \$53.37$. The 6.7% increase in the annual cost of the heat loss is small, providing little justification for using the optimal heater dimensions.

PROBLEM 3.37

KNOWN: Inner and outer radii of a tube wall which is heated electrically at its outer surface and is exposed to a fluid of prescribed h and T_∞ . Thermal contact resistance between heater and tube wall and wall inner surface temperature.

FIND: Heater power per unit length required to maintain a heater temperature of 25°C .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across heater.

ANALYSIS: The thermal circuit has the form

Applying an energy balance to a control surface about the heater,

$$\begin{aligned}
 q' &= q'_a + q'_b \\
 q' &= \frac{T_o - T_i}{\frac{\ln(r_o/r_i)}{2\pi k} + R_{t,c}} + \frac{T_o - T_\infty}{(1/h\pi D_o)} \\
 q' &= \frac{(25-5)^\circ\text{C}}{\frac{\ln(75\text{mm}/25\text{mm})}{2\pi \times 10 \text{ W/m}\cdot\text{K}} + 0.01 \frac{\text{m}\cdot\text{K}}{\text{W}}} + \frac{[25 - (-10)]^\circ\text{C}}{\left[1/\left(100 \text{ W/m}^2\cdot\text{K} \times \pi \times 0.15\text{m}\right)\right]} \\
 q' &= (728 + 1649) \text{ W/m} \\
 q' &= 2377 \text{ W/m.}
 \end{aligned}$$

COMMENTS: The conduction, contact and convection resistances are 0.0175, 0.01 and 0.021 m·K/W, respectively,

<

PROBLEM 3.38

KNOWN: Inner and outer radii of a tube wall which is heated electrically at its outer surface. Inner and outer wall temperatures. Temperature of fluid adjoining outer wall.

FIND: Effect of wall thermal conductivity, thermal contact resistance, and convection coefficient on total heater power and heat rates to outer fluid and inner surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across heater, (5) Negligible radiation.

ANALYSIS: Applying an energy balance to a control surface about the heater,

$$q' = q'_i + q'_o$$

$$q' = \frac{T_o - T_i}{\frac{\ln(r_o/r_i)}{2\pi k} + R'_{t,c}} + \frac{T_o - T_\infty}{(1/2\pi r_o h)}$$

Selecting nominal values of $k = 10 \text{ W/m}\cdot\text{K}$, $R'_{t,c} = 0.01 \text{ m}\cdot\text{K/W}$ and $h = 100 \text{ W/m}^2\cdot\text{K}$, the following parametric variations are obtained

Continued...

PROBLEM 3.38 (Cont.)

For a prescribed value of h , q_o' is fixed, while q_i' , and hence q' , increase and decrease, respectively, with increasing k and $R'_{t,c}$. These trends are attributable to the effects of k and $R'_{t,c}$ on the total (conduction plus contact) resistance separating the heater from the inner surface. For fixed k and $R'_{t,c}$, q_i' is fixed, while q_o' , and hence q' , increase with increasing h due to a reduction in the convection resistance.

COMMENTS: For the prescribed nominal values of k , $R'_{t,c}$ and h , the electric power requirement is $q' = 2377$ W/m. To maintain the prescribed heater temperature, q' would increase with any changes which reduce the conduction, contact and/or convection resistances.

PROBLEM 3.39

KNOWN: Wall thickness and diameter of stainless steel tube. Inner and outer fluid temperatures and convection coefficients.

FIND: (a) Heat gain per unit length of tube, (b) Effect of adding a 10 mm thick layer of insulation to outer surface of tube.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Negligible contact resistance between tube and insulation, (5) Negligible effect of radiation.

PROPERTIES: Table A-1, Ss 304 (~280K): $k_{st} = 14.2 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) Without the insulation, the total thermal resistance per unit length is

$$R'_{tot} = R'_{conv,i} + R'_{cond,st} + R'_{conv,o} = \frac{1}{2\pi r_1 h_i} + \frac{\ln(r_2/r_1)}{2\pi k_{st}} + \frac{1}{2\pi r_2 h_o}$$

$$R'_{tot} = \frac{1}{2\pi (0.018\text{m}) 400 \text{ W/m}^2\cdot\text{K}} + \frac{\ln(20/18)}{2\pi (14.2 \text{ W/m}\cdot\text{K})} + \frac{1}{2\pi (0.020\text{m}) 6 \text{ W/m}^2\cdot\text{K}}$$

$$R'_{tot} = (0.0221 + 1.18 \times 10^{-3} + 1.33) \text{ m}\cdot\text{K/W} = 1.35 \text{ m}\cdot\text{K/W}$$

The heat gain per unit length is then

$$q' = \frac{T_{\infty,o} - T_{\infty,i}}{R'_{tot}} = \frac{(23 - 6)^\circ\text{C}}{1.35 \text{ m}\cdot\text{K/W}} = 12.6 \text{ W/m} \quad <$$

(b) With the insulation, the total resistance per unit length is now $R'_{tot} = R'_{conv,i} + R'_{cond,st} + R'_{cond,ins} + R'_{conv,o}$, where $R'_{conv,i}$ and $R'_{cond,st}$ remain the same. The thermal resistance of the insulation is

$$R'_{cond,ins} = \frac{\ln(r_3/r_2)}{2\pi k_{ins}} = \frac{\ln(30/20)}{2\pi (0.05 \text{ W/m}\cdot\text{K})} = 1.29 \text{ m}\cdot\text{K/W}$$

and the outer convection resistance is now

$$R'_{conv,o} = \frac{1}{2\pi r_3 h_o} = \frac{1}{2\pi (0.03\text{m}) 6 \text{ W/m}^2\cdot\text{K}} = 0.88 \text{ m}\cdot\text{K/W}$$

The total resistance is now

$$R'_{tot} = (0.0221 + 1.18 \times 10^{-3} + 1.29 + 0.88) \text{ m}\cdot\text{K/W} = 2.20 \text{ m}\cdot\text{K/W}$$

Continued

PROBLEM 3.39 (Cont.)

and the heat gain per unit length is

$$q' = \frac{T_{\infty,o} - T_{\infty,i}}{R'_{\text{tot}}} = \frac{17^\circ\text{C}}{2.20 \text{ m} \cdot \text{K}/\text{W}} = 7.7 \text{ W/m}$$

COMMENTS: (1) The validity of assuming negligible radiation may be assessed for the worst case condition corresponding to the bare tube. Assuming a tube outer surface temperature of $T_s = T_{\infty,i} = 279\text{K}$, large surroundings at $T_{\text{sur}} = T_{\infty,o} = 296\text{K}$, and an emissivity of $\varepsilon = 0.7$ (Table A-11), the heat gain due to net radiation exchange with the surroundings is $q'_{\text{rad}} = \varepsilon \sigma (2\pi r_2) (T_{\text{sur}}^4 - T_s^4) = 8.1 \text{ W/m}$.

Hence, the net rate of heat transfer by radiation to the tube surface is comparable to that by convection, and the assumption of negligible radiation is inappropriate.

(2) If heat transfer from the air is by natural convection, the value of h_o with the insulation would actually be less than the value for the bare tube, thereby further reducing the heat gain. Use of the insulation would also increase the outer surface temperature, thereby reducing net radiation transfer from the surroundings.

(3) The critical radius is $r_{\text{cr}} = k_{\text{ins}}/h \approx 8 \text{ mm} < r_2$. Hence, as indicated by the calculations, heat transfer is reduced by the insulation.

PROBLEM 3.40

KNOWN: Diameter, wall thickness and thermal conductivity of steel tubes. Temperature of steam flowing through the tubes. Thermal conductivity of insulation and emissivity of aluminum sheath. Temperature of ambient air and surroundings. Convection coefficient at outer surface and maximum allowable surface temperature.

FIND: (a) Minimum required insulation thickness ($r_3 - r_2$) and corresponding heat loss per unit length, (b) Effect of insulation thickness on outer surface temperature and heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional radial conduction, (3) Negligible contact resistances at the material interfaces, (4) Negligible steam side convection resistance ($T_{\infty,i} = T_{s,i}$), (5) Negligible conduction resistance for aluminum sheath, (6) Constant properties, (7) Large surroundings.

ANALYSIS: (a) To determine the insulation thickness, an energy balance must be performed at the outer surface, where $q' = q'_{\text{conv},o} + q'_{\text{rad}}$. With $q'_{\text{conv},o} = 2\pi r_3 h_o (T_{s,o} - T_{\infty,o})$, $q'_{\text{rad}} = 2\pi r_3 \epsilon \sigma (T_{s,o}^4 - T_{\text{sur}}^4)$, $q' = (T_{s,i} - T_{s,o}) / (R'_{\text{cond,st}} + R'_{\text{cond,ins}})$, $R'_{\text{cond,st}} = \ln(r_2 / r_1) / 2\pi k_{st}$, and $R'_{\text{cond,ins}} = \ln(r_3 / r_2) / 2\pi k_{ins}$, it follows that

$$\frac{2\pi (T_{s,i} - T_{s,o})}{\frac{\ln(r_2 / r_1)}{k_{st}} + \frac{\ln(r_3 / r_2)}{k_{ins}}} = 2\pi r_3 \left[h_o (T_{s,o} - T_{\infty,o}) + \epsilon \sigma (T_{s,o}^4 - T_{\text{sur}}^4) \right]$$

$$\frac{2\pi (848 - 323) \text{ K}}{\frac{\ln(0.18 / 0.15)}{35 \text{ W/m}\cdot\text{K}} + \frac{\ln(r_3 / 0.18)}{0.10 \text{ W/m}\cdot\text{K}}} = 2\pi r_3 \left[6 \text{ W/m}^2\cdot\text{K} (323 - 300) \text{ K} + 0.20 \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 (323^4 - 300^4) \text{ K}^4 \right]$$

A trial-and-error solution yields $r_3 = 0.394 \text{ m} = 394 \text{ mm}$, in which case the insulation thickness is

$$t_{\text{ins}} = r_3 - r_2 = 214 \text{ mm} \quad <$$

The heat rate is then

$$q' = \frac{2\pi (848 - 323) \text{ K}}{\frac{\ln(0.18 / 0.15)}{35 \text{ W/m}\cdot\text{K}} + \frac{\ln(0.394 / 0.18)}{0.10 \text{ W/m}\cdot\text{K}}} = 420 \text{ W/m} \quad <$$

(b) The effects of r_3 on $T_{s,o}$ and q' have been computed and are shown below.

Continued

PROBLEM 3.40 (Cont.)

Beyond $r_3 \approx 0.40$ m, there are rapidly diminishing benefits associated with increasing the insulation thickness.

COMMENTS: Note that the thermal resistance of the insulation is much larger than that for the tube wall. For the conditions of Part (a), the radiation coefficient is $h_r = 1.37$ W/m, and the heat loss by radiation is less than 25% of that due to natural convection ($q'_{\text{rad}} = 78$ W/m, $q'_{\text{conv},o} = 342$ W/m).

PROBLEM 3.41

KNOWN: Thin electrical heater fitted between two concentric cylinders, the outer surface of which experiences convection.

FIND: (a) Electrical power required to maintain outer surface at a specified temperature, (b) Temperature at the center.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Steady-state conditions, (3) Heater element has negligible thickness, (4) Negligible contact resistance between cylinders and heater, (5) Constant properties, (6) No generation.

ANALYSIS: (a) Perform an energy balance on the composite system to determine the power required to maintain $T(r_2) = T_s = 5^\circ\text{C}$.

$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_{gen} = \dot{E}'_{st}$$

$$+q'_{elec} - q'_{conv} = 0.$$

Using Newton's law of cooling,

$$q'_{elec} = q'_{conv} = h \cdot 2\pi r_2 (T_s - T_\infty)$$

$$q'_{elec} = 50 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times 2\pi (0.040\text{m}) [5 - (-15)]^\circ\text{C} = 251 \text{ W/m}.$$

(b) From a control volume about Cylinder A, we recognize that the cylinder must be isothermal, that is,

$$T(0) = T(r_1).$$

Represent Cylinder B by a thermal circuit:

$$q' = \frac{T(r_1) - T_s}{R'_B}$$

For the cylinder, from Eq. 3.28,

$$R'_B = \ln r_2 / r_1 / 2\pi k_B$$

giving

$$T(r_1) = T_s + q' R'_B = 5^\circ\text{C} + 251 \frac{\text{W}}{\text{m}} \frac{\ln 40/20}{2\pi \times 1.5 \text{ W/m} \cdot \text{K}} = 23.5^\circ\text{C}$$

Hence, $T(0) = T(r_1) = 23.5^\circ\text{C}$.

Note that k_A has no influence on the temperature $T(0)$.

PROBLEM 3.42

KNOWN: Electric current and resistance of wire. Wire diameter and emissivity. Thickness, emissivity and thermal conductivity of coating. Temperature of ambient air and surroundings. Expression for heat transfer coefficient at surface of the wire or coating.

FIND: (a) Heat generation per unit length and volume of wire, (b) Temperature of uninsulated wire, (c) Inner and outer surface temperatures of insulation, including the effect of insulation thickness.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional radial conduction through insulation, (3) Constant properties, (4) Negligible contact resistance between insulation and wire, (5) Negligible radial temperature gradients in wire, (6) Large surroundings.

ANALYSIS: (a) The rates of energy generation per unit length and volume are, respectively,

$$\dot{E}'_g = I^2 R'_{\text{elec}} = (20 \text{ A})^2 (0.01 \Omega / \text{m}) = 4 \text{ W / m} \quad <$$

$$\dot{q} = \dot{E}'_g / A_c = 4 \dot{E}'_g / \pi D^2 = 16 \text{ W / m} / \pi (0.002 \text{ m})^2 = 1.27 \times 10^6 \text{ W / m}^3 \quad <$$

(b) Without the insulation, an energy balance at the surface of the wire yields

$$\dot{E}'_g = \dot{q}' = \dot{q}'_{\text{conv}} + \dot{q}'_{\text{rad}} = \pi D h (T - T_{\infty}) + \pi D \varepsilon_w \sigma (T^4 - T_{\text{sur}}^4)$$

where $h = 1.25[(T - T_{\infty})/D]^{1/4}$. Substituting,

$$4 \text{ W / m} = 1.25 \pi (0.002 \text{ m})^{3/4} (T - 293)^{5/4} + \pi (0.002 \text{ m}) 0.3 \times 5.67 \times 10^{-8} \text{ W / m}^2 \cdot \text{K}^4 (T^4 - 293^4) \text{ K}^4$$

and a trial-and-error solution yields

$$T = 331 \text{ K} = 58^\circ \text{C} \quad <$$

(c) Performing an energy balance at the outer surface,

$$\dot{E}'_g = \dot{q}' = \dot{q}'_{\text{conv}} + \dot{q}'_{\text{rad}} = \pi D h (T_{s,2} - T_{\infty}) + \pi D \varepsilon_i \sigma (T_{s,2}^4 - T_{\text{sur}}^4)$$

$$4 \text{ W / m} = 1.25 \pi (0.006 \text{ m})^{3/4} (T_{s,2} - 293)^{5/4} + \pi (0.006 \text{ m}) 0.9 \times 5.67 \times 10^{-8} \text{ W / m}^2 \cdot \text{K}^4 (T_{s,2}^4 - 293^4) \text{ K}^4$$

and an iterative solution yields the following value of the surface temperature

$$T_{s,2} = 307.8 \text{ K} = 34.8^\circ \text{C} \quad <$$

The inner surface temperature may then be obtained from the following expression for heat transfer by conduction in the insulation.

Continued

PROBLEM 3.42 (Cont.)

$$q' = \frac{T_{s,i} - T_{s,2}}{R'_{\text{cond}}} = \frac{T_{s,i} - T_{s,2}}{\ln(r_2/r_1)/2\pi k_i}$$

$$4 \text{ W} = \frac{2\pi (0.25 \text{ W/m}\cdot\text{K})(T_{s,i} - 307.8 \text{ K})}{\ln(3)}$$

$$T_{s,i} = 310.6 \text{ K} = 37.6^\circ\text{C}$$

<

As shown below, the effect of increasing the insulation thickness is to *reduce*, not increase, the surface temperatures.

This behavior is due to a reduction in the total resistance to heat transfer with increasing r_2 . Although the convection, h , and radiation, $h_r = \varepsilon\sigma(T_{s,2} + T_{\text{sur}})(T_{s,2}^2 + T_{\text{sur}}^2)$, coefficients decrease with increasing r_2 , the corresponding increase in the surface area is more than sufficient to provide for a reduction in the total resistance. Even for an insulation thickness of $t = 4 \text{ mm}$, $h = h + h_r = (7.1 + 5.4) \text{ W/m}^2\cdot\text{K} = 12.5 \text{ W/m}^2\cdot\text{K}$, and $r_{\text{cr}} = k/h = 0.25 \text{ W/m}\cdot\text{K}/12.5 \text{ W/m}^2\cdot\text{K} = 0.020 \text{ m} = 20 \text{ mm} > r_2 = 5 \text{ mm}$. The outer radius of the insulation is therefore well below the critical radius.

PROBLEM 3.43

KNOWN: Diameter of electrical wire. Thickness and thermal conductivity of rubberized sheath. Contact resistance between sheath and wire. Convection coefficient and ambient air temperature. Maximum allowable sheath temperature.

FIND: Maximum allowable power dissipation per unit length of wire. Critical radius of insulation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional radial conduction through insulation, (3) Constant properties, (4) Negligible radiation exchange with surroundings.

ANALYSIS: The maximum insulation temperature corresponds to its inner surface and is independent of the contact resistance. From the thermal circuit, we may write

$$\dot{E}'_g = q' = \frac{T_{in,i} - T_{\infty}}{R'_{cond} + R'_{conv}} = \frac{T_{in,i} - T_{\infty}}{\left[\ell n(r_{in,o} / r_{in,i}) / 2\pi k \right] + (1 / 2\pi r_{in,o} h)}$$

where $r_{in,i} = D/2 = 0.001\text{m}$, $r_{in,o} = r_{in,i} + t = 0.003\text{m}$, and $T_{in,i} = T_{max} = 50^{\circ}\text{C}$ yields the maximum allowable power dissipation. Hence,

$$\dot{E}'_{g,max} = \frac{(50 - 20)^{\circ}\text{C}}{\frac{\ell n 3}{2\pi \times 0.13 \text{ W/m} \cdot \text{K}} + \frac{1}{2\pi (0.003\text{m}) 10 \text{ W/m}^2 \cdot \text{K}}} = \frac{30^{\circ}\text{C}}{(1.35 + 5.31) \text{ m} \cdot \text{K/W}} = 4.51 \text{ W/m} \quad <$$

The critical insulation radius is also unaffected by the contact resistance and is given by

$$r_{cr} = \frac{k}{h} = \frac{0.13 \text{ W/m} \cdot \text{K}}{10 \text{ W/m}^2 \cdot \text{K}} = 0.013\text{m} = 13 \text{ mm} \quad <$$

Hence, $r_{in,o} < r_{cr}$ and $\dot{E}'_{g,max}$ could be increased by increasing $r_{in,o}$ up to a value of 13 mm ($t = 12$ mm).

COMMENTS: The contact resistance affects the temperature of the wire, and for $q' = \dot{E}'_{g,max} = 4.51 \text{ W/m}$, the outer surface temperature of the wire is $T_{w,o} = T_{in,i} + q' R'_{t,c} = 50^{\circ}\text{C} + (4.51 \text{ W/m}) \left(3 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} \right) / \pi (0.002\text{m}) = 50.2^{\circ}\text{C}$. Hence, the temperature change across the contact resistance is negligible.

PROBLEM 3.44

KNOWN: Long rod experiencing uniform volumetric generation of thermal energy, \dot{q} , concentric with a hollow ceramic cylinder creating an enclosure filled with air. Thermal resistance per unit length due to radiation exchange between enclosure surfaces is R'_{rad} . The free convection coefficient for the enclosure surfaces is $h = 20 \text{ W/m}^2 \cdot \text{K}$.

FIND: (a) Thermal circuit of the system that can be used to calculate the surface temperature of the rod, T_r ; label all temperatures, heat rates and thermal resistances; evaluate the thermal resistances; and (b) Calculate the surface temperature of the rod.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial conduction through the hollow cylinder, (3) The enclosure surfaces experience free convection and radiation exchange.

ANALYSIS: (a) The thermal circuit is shown below. Note labels for the temperatures, thermal resistances and the relevant heat fluxes.

Enclosure, radiation exchange (given):

$$R'_{\text{rad}} = 0.30 \text{ m} \cdot \text{K} / \text{W}$$

Enclosure, free convection:

$$R'_{\text{cv,rod}} = \frac{1}{h\pi D_r} = \frac{1}{20 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.020 \text{ m}} = 0.80 \text{ m} \cdot \text{K} / \text{W}$$

$$R'_{\text{cv,cer}} = \frac{1}{h\pi D_i} = \frac{1}{20 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.040 \text{ m}} = 0.40 \text{ m} \cdot \text{K} / \text{W}$$

Ceramic cylinder, conduction:

$$R'_{\text{cd}} = \frac{\ln(D_o/D_i)}{2\pi k} = \frac{\ln(0.120/0.040)}{2\pi \times 1.75 \text{ W/m} \cdot \text{K}} = 0.10 \text{ m} \cdot \text{K} / \text{W}$$

The thermal resistance between the enclosure surfaces (r-i) due to convection and radiation exchange is

$$\frac{1}{R'_{\text{enc}}} = \frac{1}{R'_{\text{rad}}} + \frac{1}{R'_{\text{cv,rod}} + R'_{\text{cv,cer}}}$$

$$R'_{\text{enc}} = \left[\frac{1}{0.30} + \frac{1}{0.80 + 0.40} \right]^{-1} \text{ m} \cdot \text{K} / \text{W} = 0.24 \text{ m} \cdot \text{K} / \text{W}$$

The total resistance between the rod surface (r) and the outer surface of the cylinder (o) is

$$R'_{\text{tot}} = R'_{\text{enc}} + R'_{\text{cd}} = (0.24 + 0.1) \text{ m} \cdot \text{K} / \text{W} = 0.34 \text{ m} \cdot \text{K} / \text{W}$$

Continued

PROBLEM 3.44 (Cont.)

(b) From an energy balance on the rod (see schematic) find T_r .

$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_{gen} = 0$$

$$-q + \dot{q} \forall = 0$$

$$-(T_r - T_i) / R'_{tot} + \dot{q} (\pi D_r^2 / 4) = 0$$

$$-(T_r - 25) \text{ K} / 0.34 \text{ m} \cdot \text{K} / \text{W} + 2 \times 10^6 \text{ W} / \text{m}^3 (\pi \times 0.020 \text{ m}^2 / 4) = 0$$

$$T_r = 239^\circ\text{C}$$

<

COMMENTS: In evaluating the convection resistance of the air space, it was necessary to define an average air temperature (T_∞) and consider the convection coefficients for each of the space surfaces. As you'll learn later in Chapter 9, correlations are available for directly estimating the convection coefficient (h_{enc}) for the enclosure so that $q_{cv} = h_{enc} (T_r - T_i)$.

PROBLEM 3.45

KNOWN: Tube diameter and refrigerant temperature for evaporator of a refrigerant system. Convection coefficient and temperature of outside air.

FIND: (a) Rate of heat extraction without frost formation, (b) Effect of frost formation on heat rate, (c) Time required for a 2 mm thick frost layer to melt in ambient air for which $h = 2 \text{ W/m}^2 \cdot \text{K}$ and $T_{\infty} = 20^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Negligible convection resistance for refrigerant flow ($T_{\infty,i} = T_{s,i}$), (3) Negligible tube wall conduction resistance, (4) Negligible radiation exchange at outer surface.

ANALYSIS: (a) The cooling capacity in the defrosted condition ($\delta = 0$) corresponds to the rate of heat extraction from the airflow. Hence,

$$q' = h 2\pi\eta (T_{\infty,o} - T_{s,i}) = 100 \text{ W/m}^2 \cdot \text{K} (2\pi \times 0.005 \text{ m}) (-3 + 18)^\circ\text{C}$$

$$q' = 47.1 \text{ W/m}$$

(b) With the frost layer, there is an additional (conduction) resistance to heat transfer, and the extraction rate is

$$q' = \frac{T_{\infty,o} - T_{s,i}}{R'_{\text{conv}} + R'_{\text{cond}}} = \frac{T_{\infty,o} - T_{s,i}}{1/(h 2\pi r_2) + \ln(r_2/r_1)/2\pi k}$$

For $5 \leq r_2 \leq 9 \text{ mm}$ and $k = 0.4 \text{ W/m} \cdot \text{K}$, this expression yields

Continued...

PROBLEM 3.45 (Cont.)

The heat extraction, and hence the performance of the evaporator coil, decreases with increasing frost layer thickness due to an increase in the total resistance to heat transfer. Although the convection resistance decreases with increasing δ , the reduction is exceeded by the increase in the conduction resistance.

(c) The time t_m required to melt a 2 mm thick frost layer may be determined by applying an energy balance, Eq. 1.11c, over the differential time interval dt and to a differential control volume extending inward from the surface of the layer.

$$\dot{E}_{in} dt = dE_{st} = dU_{lat}$$

$$h(2\pi rL)(T_{\infty,o} - T_f) dt = -h_{sf} \rho dV = -h_{sf} \rho (2\pi rL) dr$$

$$h(T_{\infty,o} - T_f) \int_0^{t_m} dt = -\rho h_{sf} \int_{r_2}^{r_1} dr$$

$$t_m = \frac{\rho h_{sf} (r_2 - r_1)}{h(T_{\infty,o} - T_f)} = \frac{700 \text{ kg/m}^3 (3.34 \times 10^5 \text{ J/kg})(0.002 \text{ m})}{2 \text{ W/m}^2 \cdot \text{K} (20 - 0)^\circ \text{C}}$$

$$t_m = 11,690 \text{ s} = 3.25 \text{ h}$$

<

COMMENTS: The tube radius r_1 exceeds the critical radius $r_{cr} = k/h = 0.4 \text{ W/m}\cdot\text{K}/100 \text{ W/m}^2\cdot\text{K} = 0.004 \text{ m}$, in which case any frost formation will reduce the performance of the coil.

PROBLEM 3.46

KNOWN: Conditions associated with a composite wall and a thin electric heater.

FIND: (a) Equivalent thermal circuit, (b) Expression for heater temperature, (c) Ratio of outer and inner heat flows and conditions for which ratio is minimized.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Constant properties, (3) Isothermal heater, (4) Negligible contact resistance(s).

ANALYSIS: (a) On the basis of a unit axial length, the circuit, thermal resistances, and heat rates are as shown in the schematic.

(b) Performing an energy balance for the heater, $\dot{E}_{in} = \dot{E}_{out}$, it follows that

$$q''_h (2\pi r_2) = q'_i + q'_o = \frac{T_h - T_{\infty,i}}{(h_i 2\pi r_1)^{-1} + \frac{\ln(r_2/r_1)}{2\pi k_B}} + \frac{T_h - T_{\infty,o}}{(h_o 2\pi r_3)^{-1} + \frac{\ln(r_3/r_2)}{2\pi k_A}} \quad <$$

(c) From the circuit,

$$\frac{q'_o}{q'_i} = \frac{(T_h - T_{\infty,o})}{(T_h - T_{\infty,i})} \times \frac{(h_i 2\pi r_1)^{-1} + \frac{\ln(r_2/r_1)}{2\pi k_B}}{(h_o 2\pi r_3)^{-1} + \frac{\ln(r_3/r_2)}{2\pi k_A}} \quad <$$

To reduce q'_o/q'_i , one could increase k_B , h_i , and r_3/r_2 , while reducing k_A , h_o and r_2/r_1 .

COMMENTS: Contact resistances between the heater and materials A and B could be important.

PROBLEM 3.47

KNOWN: Electric current flow, resistance, diameter and environmental conditions associated with a cable.

FIND: (a) Surface temperature of bare cable, (b) Cable surface and insulation temperatures for a thin coating of insulation, (c) Insulation thickness which provides the lowest value of the maximum insulation temperature. Corresponding value of this temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r , (3) Constant properties.

ANALYSIS: (a) The rate at which heat is transferred to the surroundings is fixed by the rate of heat generation in the cable. Performing an energy balance for a control surface about the cable, it follows that $\dot{E}_g = \dot{Q}$, or, for the bare cable, $I^2 R'_{tc} L = h (\pi D_i L) (T_s - T_{\infty})$. With

$\dot{Q}' = I^2 R'_{tc} = (700 \text{ A})^2 (6 \times 10^{-4} \Omega/\text{m}) = 294 \text{ W/m}$, it follows that

$$T_s = T_{\infty} + \frac{\dot{Q}'}{h \pi D_i} = 30^\circ \text{C} + \frac{294 \text{ W/m}}{(25 \text{ W/m}^2 \cdot \text{K}) \pi (0.005 \text{ m})}$$

$$T_s = 778.7^\circ \text{C}.$$

(b) With a thin coating of insulation, there exist contact and convection resistances to heat transfer from the cable. The heat transfer rate is determined by heating within the cable, however, and therefore remains the same.

$$\dot{Q} = \frac{T_s - T_{\infty}}{R'_{t,c} + \frac{1}{h \pi D_i L}} = \frac{T_s - T_{\infty}}{\frac{R'_{t,c}}{\pi D_i L} + \frac{1}{h \pi D_i L}}$$

$$\dot{Q}' = \frac{\pi D_i (T_s - T_{\infty})}{R'_{t,c} + 1/h}$$

and solving for the surface temperature, find

$$T_s = \frac{\dot{Q}'}{\pi D_i} \left[R'_{t,c} + \frac{1}{h} \right] + T_{\infty} = \frac{294 \text{ W/m}}{\pi (0.005 \text{ m})} \left[0.02 \frac{\text{m}^2 \cdot \text{K}}{\text{W}} + 0.04 \frac{\text{m}^2 \cdot \text{K}}{\text{W}} \right] + 30^\circ \text{C}$$

$$T_s = 1153^\circ \text{C}.$$

Continued

PROBLEM 3.47 (Cont.)

The insulation temperature is then obtained from

$$q = \frac{T_s - T_i}{R_{t,c}}$$

or

$$T_i = T_s - qR_{t,c} = 1153^\circ\text{C} - q \frac{R_{t,c}''}{\pi D_i L} = 1153^\circ\text{C} - \frac{294 \frac{\text{W}}{\text{m}} \times 0.02 \frac{\text{m}^2 \cdot \text{K}}{\text{W}}}{\pi (0.005\text{m})}$$

$$T_i = 778.7^\circ\text{C},$$

<

(c) The maximum insulation temperature could be reduced by reducing the resistance to heat transfer from the outer surface of the insulation. Such a reduction is possible if $D_i < D_{cr}$. From Example 3.5,

$$r_{cr} = \frac{k}{h} = \frac{0.5 \text{ W/m} \cdot \text{K}}{25 \text{ W/m}^2 \cdot \text{K}} = 0.02\text{m}.$$

Hence, $D_{cr} = 0.04\text{m} > D_i = 0.005\text{m}$. To minimize the maximum temperature, which exists at the inner surface of the insulation, add insulation in the amount

$$t = \frac{D_o - D_i}{2} = \frac{D_{cr} - D_i}{2} = \frac{(0.04 - 0.005)\text{m}}{2}$$

$$t = 0.0175\text{m}.$$

<

The cable surface temperature may then be obtained from

$$q' = \frac{T_s - T_\infty}{\frac{R_{t,c}''}{\pi D_i} + \frac{\ln(D_{cr}/D_i)}{2\pi k} + \frac{1}{h\pi D_{cr}}} = \frac{T_s - 30^\circ\text{C}}{\frac{0.02 \text{ m}^2 \cdot \text{K/W}}{\pi (0.005\text{m})} + \frac{\ln(0.04/0.005)}{2\pi (0.5 \text{ W/m} \cdot \text{K})} + \frac{1}{25 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \pi (0.04\text{m})}}$$

Hence,

$$294 \frac{\text{W}}{\text{m}} = \frac{T_s - 30^\circ\text{C}}{(1.27 + 0.66 + 0.32) \text{ m} \cdot \text{K/W}} = \frac{T_s - 30^\circ\text{C}}{2.25 \text{ m} \cdot \text{K/W}}$$

$$T_s = 692.5^\circ\text{C}$$

Recognizing that $q = (T_s - T_i)/R_{t,c}$, find

$$T_i = T_s - qR_{t,c} = T_s - q \frac{R_{t,c}''}{\pi D_i L} = 692.5^\circ\text{C} - \frac{294 \frac{\text{W}}{\text{m}} \times 0.02 \frac{\text{m}^2 \cdot \text{K}}{\text{W}}}{\pi (0.005\text{m})}$$

$$T_i = 318.2^\circ\text{C}.$$

<

COMMENTS: Use of the critical insulation thickness in lieu of a thin coating has the effect of reducing the maximum insulation temperature from 778.7°C to 318.2°C . Use of the critical insulation thickness also reduces the cable surface temperature to 692.5°C from 778.7°C with no insulation or from 1153°C with a thin coating.

PROBLEM 3.48

KNOWN: Saturated steam conditions in a pipe with prescribed surroundings.

FIND: (a) Heat loss per unit length from bare pipe and from insulated pipe, (b) Pay back period for insulation.

SCHEMATIC:

Steam Costs:

\$4 for 10^9 J

Insulation Cost:

\$100 per meter

Operation time:

7500 h/yr

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Negligible pipe wall resistance, (5) Negligible steam side convection resistance (pipe inner surface temperature is equal to steam temperature), (6) Negligible contact resistance, (7) $T_{sur} = T_{\infty}$.

PROPERTIES: Table A-6, Saturated water ($p = 20$ bar): $T_{sat} = T_s = 486\text{K}$; Table A-3, Magnesia, 85% ($T \approx 392\text{K}$): $k = 0.058$ W/m·K.

ANALYSIS: (a) Without the insulation, the heat loss may be expressed in terms of radiation and convection rates,

$$q' = \varepsilon \pi D \sigma (T_s^4 - T_{sur}^4) + h(\pi D)(T_s - T_{\infty})$$

$$q' = 0.8 \pi (0.2\text{m}) 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} (486^4 - 298^4) \text{K}^4$$

$$+ 20 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (\pi \times 0.2\text{m}) (486 - 298) \text{K}$$

$$q' = (1365 + 2362) \text{W/m} = 3727 \text{W/m}.$$

With the insulation, the thermal circuit is of the form

Continued

PROBLEM 3.48 (Cont.)

From an energy balance at the outer surface of the insulation,

$$\begin{aligned} \frac{q'_{\text{cond}}}{T_{s,i} - T_{s,o}} &= q'_{\text{conv}} + q'_{\text{rad}} \\ \frac{1}{\ln(D_o/D_i)/2\pi k} &= h\pi D_o (T_{s,o} - T_\infty) + \varepsilon\sigma\pi D_o (T_{s,o}^4 - T_{\text{sur}}^4) \\ \frac{(486 - T_{s,o})\text{K}}{\ln(0.3\text{m}/0.2\text{m})} &= 20 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \pi (0.3\text{m}) (T_{s,o} - 298\text{K}) \\ &\quad + 0.8 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \pi (0.3\text{m}) (T_{s,o}^4 - 298^4)\text{K}^4. \end{aligned}$$

By trial and error, we obtain

$$T_{s,o} \approx 305\text{K}$$

in which case

$$q' = \frac{(486 - 305)\text{K}}{\frac{\ln(0.3\text{m}/0.2\text{m})}{2\pi(0.055 \text{ W/m} \cdot \text{K})}} = 163 \text{ W/m.} \quad <$$

(b) The yearly energy savings per unit length of pipe due to use of the insulation is

$$\begin{aligned} \frac{\text{Savings}}{\text{Yr} \cdot \text{m}} &= \frac{\text{Energy Savings}}{\text{Yr.}} \times \frac{\text{Cost}}{\text{Energy}} \\ \frac{\text{Savings}}{\text{Yr} \cdot \text{m}} &= (3727 - 163) \frac{\text{J}}{\text{s} \cdot \text{m}} \times 3600 \frac{\text{s}}{\text{h}} \times 7500 \frac{\text{h}}{\text{Yr}} \times \frac{\$4}{10^9 \text{ J}} \\ \frac{\text{Savings}}{\text{Yr} \cdot \text{m}} &= \$385 / \text{Yr} \cdot \text{m}. \end{aligned}$$

The pay back period is then

$$\text{Pay Back Period} = \frac{\text{Insulation Costs}}{\text{Savings/Yr.} \cdot \text{m}} = \frac{\$100/\text{m}}{\$385/\text{Yr} \cdot \text{m}}$$

$$\text{Pay Back Period} = 0.26 \text{ Yr} = 3.1 \text{ mo.} \quad <$$

COMMENTS: Such a low pay back period is more than sufficient to justify investing in the insulation.

PROBLEM 3.49

KNOWN: Temperature and convection coefficient associated with steam flow through a pipe of prescribed inner and outer diameters. Outer surface emissivity and convection coefficient. Temperature of ambient air and surroundings.

FIND: Heat loss per unit length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Surroundings form a large enclosure about pipe.

PROPERTIES: Table A-1, Steel, AISI 1010 ($T \approx 450$ K): $k = 56.5$ W/m·K.

ANALYSIS: Referring to the thermal circuit, it follows from an energy balance on the outer surface that

$$\frac{T_{w,i} - T_{s,o}}{R_{\text{conv},i} + R_{\text{cond}}} = \frac{T_{s,o} - T_{w,o}}{R_{\text{conv},o}} + \frac{T_{s,o} - T_{\text{sur}}}{R_{\text{rad}}}$$

or from Eqs. 3.9, 3.28 and 1.7,

$$\begin{aligned} \frac{T_{w,i} - T_{s,o}}{(1/\pi D_i h_i) + \ln(D_o/D_i)/2\pi k} &= \frac{T_{s,o} - T_{w,o}}{(1/\pi D_o h_o)} + \frac{T_{s,o} - T_{\text{sur}}}{\frac{1}{\epsilon \pi D_o \sigma} \left(T_{s,o}^4 - T_{\text{sur}}^4 \right)} \\ \frac{523 - T_{s,o}}{\left(\pi \times 0.06 \times 500 \text{ W/m}^2 \cdot \text{K} \right)^{-1} + \frac{\ln(75/60)}{2\pi \times 56.5 \text{ W/m} \cdot \text{K}}} &= \frac{T_{s,o} - 293}{\left(\pi \times 0.075 \times 25 \text{ W/m}^2 \cdot \text{K} \right)^{-1} + \frac{1}{0.8 \pi \times (0.075 \text{ m}) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \left[T_{s,o}^4 - 293^4 \right] \text{ K}^4} \\ \frac{523 - T_{s,o}}{0.0106 + 0.0006} &= \frac{T_{s,o} - 293}{0.170} + 1.07 \times 10^{-8} \left[T_{s,o}^4 - 293^4 \right] \end{aligned}$$

From a trial-and-error solution, $T_{s,o} \approx 502$ K. Hence the heat loss is

$$q' = \pi D_o h_o (T_{s,o} - T_{w,o}) + \epsilon \pi D_o \sigma (T_{s,o}^4 - T_{\text{sur}}^4)$$

$$q' = \pi (0.075 \text{ m}) 25 \text{ W/m}^2 \cdot \text{K} (502 - 293) + 0.8 \pi (0.075 \text{ m}) 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} [502^4 - 293^4] \text{ K}^4$$

$$q' = 1231 \text{ W/m} + 600 \text{ W/m} = 1831 \text{ W/m.}$$

COMMENTS: The thermal resistance between the outer surface and the surroundings is much larger than that between the outer surface and the steam.

PROBLEM 3.50

KNOWN: Temperature and convection coefficient associated with steam flow through a pipe of prescribed inner and outer radii. Emissivity of outer surface magnesia insulation, and convection coefficient. Temperature of ambient air and surroundings.

FIND: Heat loss per unit length q' and outer surface temperature $T_{s,o}$ as a function of insulation thickness. Recommended insulation thickness. Corresponding annual savings and temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Surroundings form a large enclosure about pipe.

PROPERTIES: Table A-1, Steel, AISI 1010 ($T \approx 450$ K): $k_s = 56.5$ W/m·K. Table A-3, Magnesia, 85% ($T \approx 365$ K): $k_m = 0.055$ W/m·K.

ANALYSIS: Referring to the thermal circuit, it follows from an energy balance on the outer surface that

$$\frac{T_{\infty,i} - T_{s,o}}{R'_{\text{conv},i} + R'_{\text{cond},s} + R'_{\text{cond},m}} = \frac{T_{s,o} - T_{\infty,o}}{R'_{\text{conv},o}} + \frac{T_{s,o} - T_{\text{sur}}}{R'_{\text{rad}}}$$

or from Eqs. 3.9, 3.28 and 1.7,

$$\frac{T_{\infty,i} - T_{s,o}}{(1/2\pi\eta h_i) + \ln(r_2/\eta)/2\pi k_s + \ln(r_3/r_2)/2\pi k_m} = \frac{T_{s,o} - T_{\infty,o}}{(1/2\pi r_3 h_o)} + \frac{T_{s,o} - T_{\text{sur}}}{\left[(2\pi r_3) \epsilon \sigma (T_{s,o} + T_{\text{sur}}) (T_{s,o}^2 + T_{\text{sur}}^2) \right]^{-1}}$$

This expression may be solved for $T_{s,o}$ as a function of r_3 , and the heat loss may then be determined by evaluating either the left-or right-hand side of the energy balance equation. The results are plotted as follows.

Continued...

PROBLEM 3.50 (Cont.)

The rapid decay in q' with increasing r_3 is attributable to the dominant contribution which the insulation begins to make to the total thermal resistance. The inside convection and tube wall conduction resistances are fixed at $0.0106 \text{ m}^2\cdot\text{K}/\text{W}$ and $6.29 \times 10^{-4} \text{ m}^2\cdot\text{K}/\text{W}$, respectively, while the resistance of the insulation increases to approximately $2 \text{ m}^2\cdot\text{K}/\text{W}$ at $r_3 = 0.075 \text{ m}$.

The heat loss may be reduced by almost 91% from a value of approximately 1830 W/m at $r_3 = r_2 = 0.0375 \text{ m}$ (no insulation) to 172 W/m at $r_3 = 0.0575 \text{ m}$ and by only an additional 3% if the insulation thickness is increased to $r_3 = 0.0775 \text{ m}$. Hence, an insulation thickness of $(r_3 - r_2) = 0.020 \text{ m}$ is recommended, for which $q' = 172 \text{ W/m}$. The corresponding annual savings (AS) in energy costs is therefore

$$AS = [(1830 - 172) \text{ W/m}] \frac{\$4}{10^9 \text{ J}} \times 7000 \frac{\text{h}}{\text{y}} \times 3600 \frac{\text{s}}{\text{h}} = \$167 / \text{m}$$

<

The corresponding temperature distribution is

The temperature in the insulation decreases from $T(r) = T_2 = 521 \text{ K}$ at $r = r_2 = 0.0375 \text{ m}$ to $T(r) = T_3 = 309 \text{ K}$ at $r = r_3 = 0.0575 \text{ m}$.

Continued...

PROBLEM 3.50 (Cont.)

COMMENTS: 1. The annual energy and costs savings associated with insulating the steam line are substantial, as is the reduction in the outer surface temperature (from $T_{s,o} \approx 502$ K for $r_3 = r_2$, to 309 K for $r_3 = 0.0575$ m).

2. The increase in R'_{rad} to a maximum value of 0.63 m·K/W at $r_3 = 0.0455$ m and the subsequent decay is due to the competing effects of h_{rad} and $A'_3 = 2\pi r_3$. Because the initial decay in $T_3 = T_{s,o}$ with increasing r_3 , and hence, the reduction in h_{rad} , is more pronounced than the increase in A'_3 , R'_{rad} increases with r_3 . However, as the decay in $T_{s,o}$, and hence h_{rad} , becomes less pronounced, the increase in A'_3 becomes more pronounced and R'_{rad} decreases with increasing r_3 .

PROBLEM 3.51

KNOWN: Pipe wall temperature and convection conditions associated with water flow through the pipe and ice layer formation on the inner surface.

FIND: Ice layer thickness δ .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Negligible pipe wall thermal resistance, (3) negligible ice/wall contact resistance, (4) Constant k .

PROPERTIES: Table A.3, Ice ($T = 265$ K): $k \approx 1.94$ W/m·K.

ANALYSIS: Performing an energy balance for a control surface about the ice/water interface, it follows that, for a unit length of pipe,

$$\dot{q}_{\text{conv}} = \dot{q}_{\text{cond}}$$

$$h_i (2\pi r_1) (T_{\infty,i} - T_{s,i}) = \frac{T_{s,i} - T_{s,o}}{\ln(r_2/r_1)/2\pi k}$$

Dividing both sides of the equation by r_2 ,

$$\frac{\ln(r_2/r_1)}{(r_2/r_1)} = \frac{k}{h_i r_2} \times \frac{T_{s,i} - T_{s,o}}{T_{\infty,i} - T_{s,i}} = \frac{1.94 \text{ W/m} \cdot \text{K}}{(2000 \text{ W/m}^2 \cdot \text{K})(0.05 \text{ m})} \times \frac{15^\circ \text{C}}{3^\circ \text{C}} = 0.097$$

The equation is satisfied by $r_2/r_1 = 1.114$, in which case $r_1 = 0.050 \text{ m}/1.114 = 0.045 \text{ m}$, and the ice layer thickness is

$$\delta = r_2 - r_1 = 0.005 \text{ m} = 5 \text{ mm}$$

<

COMMENTS: With no flow, $h_i \rightarrow 0$, in which case $r_1 \rightarrow 0$ and complete blockage could occur. The pipe should be insulated.

PROBLEM 3.52

KNOWN: Inner surface temperature of insulation blanket comprised of two semi-cylindrical shells of different materials. Ambient air conditions.

FIND: (a) Equivalent thermal circuit, (b) Total heat loss and material outer surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial conduction, (3) Infinite contact resistance between materials, (4) Constant properties.

ANALYSIS: (a) The thermal circuit is,

$$R'_{\text{conv},A} = R'_{\text{conv},B} = 1 / \pi r_2 h$$

$$R'_{\text{cond}}(A) = \frac{\ln(r_2 / r_1)}{\pi k_A}$$

$$R'_{\text{cond}}(B) = \frac{\ln(r_2 / r_1)}{\pi k_B}$$

The conduction resistances follow from Section 3.3.1 and Eq. 3.28. Each resistance is larger by a factor of 2 than the result of Eq. 3.28 due to the reduced area.

(b) Evaluating the thermal resistances and the heat rate ($q' = q'_A + q'_B$),

$$R'_{\text{conv}} = \left(\pi \times 0.1 \text{ m} \times 25 \text{ W/m}^2 \cdot \text{K} \right)^{-1} = 0.1273 \text{ m} \cdot \text{K/W}$$

$$R'_{\text{cond}}(A) = \frac{\ln(0.1 \text{ m} / 0.05 \text{ m})}{\pi \times 2 \text{ W/m} \cdot \text{K}} = 0.1103 \text{ m} \cdot \text{K/W} \quad R'_{\text{cond}}(B) = 8 R'_{\text{cond}}(A) = 0.8825 \text{ m} \cdot \text{K/W}$$

$$q' = \frac{T_{s,1} - T_\infty}{R'_{\text{cond}}(A) + R'_{\text{conv}}} + \frac{T_{s,1} - T_\infty}{R'_{\text{cond}}(B) + R'_{\text{conv}}}$$

$$q' = \frac{(500 - 300) \text{ K}}{(0.1103 + 0.1273) \text{ m} \cdot \text{K/W}} + \frac{(500 - 300) \text{ K}}{(0.8825 + 0.1273) \text{ m} \cdot \text{K/W}} = (842 + 198) \text{ W/m} = 1040 \text{ W/m.}$$

Hence, the temperatures are

$$T_{s,2}(A) = T_{s,1} - q'_A R'_{\text{cond}}(A) = 500 \text{ K} - 842 \frac{\text{W}}{\text{m}} \times 0.1103 \frac{\text{m} \cdot \text{K}}{\text{W}} = 407 \text{ K}$$

$$T_{s,2}(B) = T_{s,1} - q'_B R'_{\text{cond}}(B) = 500 \text{ K} - 198 \frac{\text{W}}{\text{m}} \times 0.8825 \frac{\text{m} \cdot \text{K}}{\text{W}} = 325 \text{ K.}$$

COMMENTS: The total heat loss can also be computed from $q' = (T_{s,1} - T_\infty) / R_{\text{equiv}}$,

$$\text{where } R_{\text{equiv}} = \left[\left(R'_{\text{cond}}(A) + R'_{\text{conv},A} \right)^{-1} + \left(R'_{\text{cond}}(B) + R'_{\text{conv},B} \right)^{-1} \right]^{-1} = 0.1923 \text{ m} \cdot \text{K/W.}$$

$$\text{Hence } q' = (500 - 300) \text{ K} / 0.1923 \text{ m} \cdot \text{K/W} = 1040 \text{ W/m.}$$

PROBLEM 3.53

KNOWN: Surface temperature of a circular rod coated with Bakelite and adjoining fluid conditions.

FIND: (a) Critical insulation radius, (b) Heat transfer per unit length for bare rod and for insulation at critical radius, (c) Insulation thickness needed for 25% heat rate reduction.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r , (3) Constant properties, (4) Negligible radiation and contact resistance.

PROPERTIES: Table A-3, Bakelite (300K): $k = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) From Example 3.5, the critical radius is

$$r_{cr} = \frac{k}{h} = \frac{1.4 \text{ W/m}\cdot\text{K}}{140 \text{ W/m}^2\cdot\text{K}} = 0.01 \text{ m.}$$

(b) For the bare rod,

$$q' = h(\pi D_i) (T_i - T_\infty)$$

$$q' = 140 \frac{\text{W}}{\text{m}^2\cdot\text{K}} (\pi \times 0.01 \text{ m}) (200 - 25)^\circ\text{C} = 770 \text{ W/m}$$

For the critical insulation thickness,

$$q' = \frac{T_i - T_\infty}{\frac{1}{2\pi r_{cr} h} + \frac{\ln(r_{cr}/r_i)}{2\pi k}} = \frac{(200 - 25)^\circ\text{C}}{\frac{1}{2\pi \times (0.01 \text{ m}) \times 140 \text{ W/m}^2\cdot\text{K}} + \frac{\ln(0.01 \text{ m}/0.005 \text{ m})}{2\pi \times 1.4 \text{ W/m}\cdot\text{K}}}$$

$$q' = \frac{175^\circ\text{C}}{(0.1137 + 0.0788) \text{ m}\cdot\text{K/W}} = 909 \text{ W/m}$$

(c) The insulation thickness needed to reduce the heat rate to 577 W/m is obtained from

$$q' = \frac{T_i - T_\infty}{\frac{1}{2\pi r h} + \frac{\ln(r/r_i)}{2\pi k}} = \frac{(200 - 25)^\circ\text{C}}{\frac{1}{2\pi(r)140 \text{ W/m}^2\cdot\text{K}} + \frac{\ln(r/0.005 \text{ m})}{2\pi \times 1.4 \text{ W/m}\cdot\text{K}}} = 577 \frac{\text{W}}{\text{m}}$$

From a trial-and-error solution, find

$$r \approx 0.06 \text{ m.}$$

The desired insulation thickness is then

$$\delta = (r - r_i) \approx (0.06 - 0.005) \text{ m} = 55 \text{ mm.}$$

PROBLEM 3.54

KNOWN: Geometry of an oil storage tank. Temperature of stored oil and environmental conditions.

FIND: Heater power required to maintain a prescribed inner surface temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in radial direction, (3) Constant properties, (4) Negligible radiation.

PROPERTIES: Table A-3, Pyrex (300K): $k = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: The rate at which heat must be supplied is equal to the loss through the cylindrical and hemispherical sections. Hence,

$$q = q_{\text{cyl}} + 2q_{\text{hemi}} = q_{\text{cyl}} + q_{\text{spher}}$$

or, from Eqs. 3.28 and 3.36,

$$\begin{aligned}
 q &= \frac{T_{s,i} - T_{\infty}}{\frac{\ln(D_o/D_i)}{2\pi Lk} + \frac{1}{\pi D_o Lh}} + \frac{T_{s,i} - T_{\infty}}{\frac{1}{2\pi k} \left[\frac{1}{D_i} - \frac{1}{D_o} \right] + \frac{1}{\pi D_o^2 h}} \\
 q &= \frac{(400 - 300)\text{K}}{\frac{\ln 1.04}{2\pi(2\text{m})1.4 \text{ W/m}\cdot\text{K}} + \frac{1}{\pi(1.04\text{m})2\text{m}(10 \text{ W/m}^2\cdot\text{K})}} + \frac{(400 - 300)\text{K}}{\frac{1}{2\pi(1.4 \text{ W/m}\cdot\text{K})} \left(\frac{1}{1\text{m}} - \frac{1}{1.04\text{m}} \right) + \frac{1}{\pi(1.04\text{m})^2 10 \text{ W/m}^2\cdot\text{K}}} \\
 q &= \frac{100\text{K}}{2.23 \times 10^{-3} \text{ K/W} + 15.30 \times 10^{-3} \text{ K/W}} + \frac{100\text{K}}{4.32 \times 10^{-3} \text{ K/W} + 29.43 \times 10^{-3} \text{ K/W}} \\
 q &= 5705\text{W} + 2963\text{W} = 8668\text{W}.
 \end{aligned}$$

<

PROBLEM 3.55

KNOWN: Diameter of a spherical container used to store liquid oxygen and properties of insulating material. Environmental conditions.

FIND: (a) Reduction in evaporative oxygen loss associated with a prescribed insulation thickness, (b) Effect of insulation thickness on evaporation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Negligible conduction resistance of container wall and contact resistance between wall and insulation, (3) Container wall at boiling point of liquid oxygen.

ANALYSIS: (a) Applying an energy balance to a control surface about the insulation, $\dot{E}_{in} - \dot{E}_{out} = 0$, it follows that $q_{conv} + q_{rad} = q_{cond} = q$. Hence,

$$\frac{T_{\infty} - T_{s,2}}{R_{t,conv}} + \frac{T_{sur} - T_{s,2}}{R_{t,rad}} = \frac{T_{s,2} - T_{s,1}}{R_{t,cond}} = q \quad (1)$$

where $R_{t,conv} = \left(4\pi r_2^2 h\right)^{-1}$, $R_{t,rad} = \left(4\pi r_2^2 h_r\right)^{-1}$, $R_{t,cond} = \left(1/4\pi k\right)\left[\left(1/r_1\right) - \left(1/r_2\right)\right]$, and, from Eq.

1.9, the radiation coefficient is $h_r = \varepsilon \sigma \left(T_{s,2} + T_{sur}\right) \left(T_{s,2}^2 + T_{sur}^2\right)$. With $t = 10$ mm ($r_2 = 260$ mm), $\varepsilon = 0.2$ and $T_{\infty} = T_{sur} = 298$ K, an iterative solution of the energy balance equation yields $T_{s,2} \approx 297.7$ K, where $R_{t,conv} = 0.118$ K/W, $R_{t,rad} = 0.982$ K/W and $R_{t,cond} = 76.5$ K/W. With the insulation, it follows that the heat gain is

$$q_w \approx 2.72 \text{ W}$$

Without the insulation, the heat gain is

$$q_{wo} = \frac{T_{\infty} - T_{s,1}}{R_{t,conv}} + \frac{T_{sur} - T_{s,1}}{R_{t,rad}}$$

where, with $r_2 = r_1$, $T_{s,1} = 90$ K, $R_{t,conv} = 0.127$ K/W and $R_{t,rad} = 3.14$ K/W. Hence,

$$q_{wo} = 1702 \text{ W}$$

With the oxygen mass evaporation rate given by $\dot{m} = q/h_{fg}$, the percent reduction in evaporated oxygen is

$$\% \text{ Reduction} = \frac{\dot{m}_{wo} - \dot{m}_w}{\dot{m}_{wo}} \times 100\% = \frac{q_{wo} - q_w}{q_{wo}} \times 100\%$$

Hence,

$$\% \text{ Reduction} = \frac{(1702 - 2.7) \text{ W}}{1702 \text{ W}} \times 100\% = 99.8\%$$

<

Continued...

PROBLEM 3.55 (Cont.)

(b) Using Equation (1) to compute $T_{s,2}$ and q as a function of r_2 , the corresponding evaporation rate, $\dot{m} = q/h_{fg}$, may be determined. Variations of q and \dot{m} with r_2 are plotted as follows.

Because of its extremely low thermal conductivity, significant benefits are associated with using even a thin layer of insulation. Nearly three-order magnitude reductions in q and \dot{m} are achieved with $r_2 = 0.26$ m. With increasing r_2 , q and \dot{m} decrease from values of 1702 W and 8×10^{-3} kg/s at $r_2 = 0.25$ m to 0.627 W and 2.9×10^{-6} kg/s at $r_2 = 0.30$ m.

COMMENTS: Laminated metallic-foil/glass-mat insulations are extremely effective and corresponding conduction resistances are typically much larger than those normally associated with surface convection and radiation.

PROBLEM 3.56

KNOWN: Sphere of radius r_i , covered with insulation whose outer surface is exposed to a convection process.

FIND: Critical insulation radius, r_{cr} .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial (spherical) conduction, (3) Constant properties, (4) Negligible radiation at surface.

ANALYSIS: The heat rate follows from the thermal circuit shown in the schematic,

$$q = (T_i - T_\infty) / R_{tot}$$

where $R_{tot} = R_{t,conv} + R_{t,cond}$ and

$$R_{t,conv} = \frac{1}{hA_s} = \frac{1}{4\pi hr^2} \quad (3.9)$$

$$R_{t,cond} = \frac{1}{4\pi k} \left[\frac{1}{r_i} - \frac{1}{r} \right] \quad (3.36)$$

If q is a maximum or minimum, we need to find the condition for which

$$\frac{dR_{tot}}{dr} = 0,$$

It follows that

$$\frac{d}{dr} \left[\frac{1}{4\pi k} \left[\frac{1}{r_i} - \frac{1}{r} \right] + \frac{1}{4\pi hr^2} \right] = \left[+\frac{1}{4\pi k} \frac{1}{r^2} - \frac{1}{2\pi h} \frac{1}{r^3} \right] = 0$$

giving

$$r_{cr} = 2 \frac{k}{h}$$

The second derivative, evaluated at $r = r_{cr}$, is

$$\begin{aligned} \frac{d}{dr} \left[\frac{dR_{tot}}{dr} \right] &= -\frac{1}{2\pi k} \frac{1}{r^3} + \frac{3}{2\pi h} \frac{1}{r^4} \bigg|_{r=r_{cr}} \\ &= \frac{1}{(2k/h)^3} \left\{ -\frac{1}{2\pi k} + \frac{3}{2\pi h} \frac{1}{2k/h} \right\} = \frac{1}{(2k/h)^3} \frac{1}{2\pi k} \left\{ -1 + \frac{3}{2} \right\} > 0 \end{aligned}$$

Hence, it follows no optimum R_{tot} exists. We refer to this condition as the critical insulation radius. See Example 3.5 which considers this situation for a cylindrical system.

PROBLEM 3.57

KNOWN: Thickness of hollow aluminum sphere and insulation layer. Heat rate and inner surface temperature. Ambient air temperature and convection coefficient.

FIND: Thermal conductivity of insulation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Negligible radiation exchange at outer surface.

PROPERTIES: Table A-1, Aluminum (523K): $k \approx 230$ W/m·K.

ANALYSIS: From the thermal circuit,

$$q = \frac{T_1 - T_\infty}{R_{\text{tot}}} = \frac{T_1 - T_\infty}{\frac{1/r_1 - 1/r_2}{4\pi k_{Al}} + \frac{1/r_2 - 1/r_3}{4\pi k_I} + \frac{1}{h4\pi r_3^2}}$$

$$q = \frac{(250 - 20)^\circ\text{C}}{\left[\frac{1/0.15 - 1/0.18}{4\pi(230)} + \frac{1/0.18 - 1/0.30}{4\pi k_I} + \frac{1}{30(4\pi)(0.3)^2} \right] \frac{\text{K}}{\text{W}}} = 80 \text{ W}$$

or

$$3.84 \times 10^{-4} + \frac{0.177}{k_I} + 0.0029 = \frac{230}{80} = 2.875.$$

Solving for the unknown thermal conductivity, find

$$k_I = 0.062 \text{ W/m·K.}$$

<

COMMENTS: The dominant contribution to the total thermal resistance is made by the insulation. Hence uncertainties in knowledge of h or k_{Al} have a negligible effect on the accuracy of the k_I measurement.

PROBLEM 3.58

KNOWN: Dimensions of spherical, stainless steel liquid oxygen (LOX) storage container. Boiling point and latent heat of fusion of LOX. Environmental temperature.

FIND: Thermal isolation system which maintains boil-off below 1 kg/day.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Negligible thermal resistances associated with internal and external convection, conduction in the container wall, and contact between wall and insulation, (3) Negligible radiation at exterior surface (due to low emissivity insulation selected), (4) Constant insulation thermal conductivity.

PROPERTIES: Table A.1, 304 Stainless steel ($T = 100 \text{ K}$): $k_s = 9.2 \text{ W/m}\cdot\text{K}$; Table A.3, Reflective, aluminum foil-glass paper insulation ($T = 150 \text{ K}$): $k_i = 0.000017 \text{ W/m}\cdot\text{K}$ (see choice of insulation below).

ANALYSIS: The heat gain associated with a loss of 1 kg/day is

$$\dot{q} = \dot{m} h_{fg} = \frac{1 \text{ kg/day}}{86,400 \text{ s/day}} (2.13 \times 10^5 \text{ J/kg}) = 2.47 \text{ W}$$

With an overall temperature difference of $(T_\infty - T_{bp}) = 150 \text{ K}$, the corresponding total thermal resistance is

$$R_{\text{tot}} = \frac{\Delta T}{\dot{q}} = \frac{150 \text{ K}}{2.47 \text{ W}} = 60.7 \text{ K/W}$$

The conduction resistance of the steel wall is

$$R_{t,\text{cond},s} = \frac{1}{4\pi k_s} \left(\frac{1}{r_1} - \frac{1}{r_2} \right) = \frac{1}{4\pi (9.2 \text{ W/m}\cdot\text{K})} \left(\frac{1}{0.395 \text{ m}} - \frac{1}{0.40 \text{ m}} \right) = 2.7 \times 10^{-4} \text{ K/W}$$

With a typical combined radiation and convection heat transfer coefficient of $h = 10 \text{ W/m}^2\cdot\text{K}$, the resistance between the surface and the environment can be estimated as

$$R_{\text{conv},\text{rad}} = \frac{1}{hA_s} = \frac{1}{10 \text{ W/m}^2\cdot\text{K} \times 4\pi (0.40 \text{ m})^2} = 0.05 \text{ K/W}$$

It is clear that these resistances are insufficient, and reliance must be placed on the insulation. A special insulation of very low thermal conductivity should be selected. The best choice is a highly reflective foil/glass matted insulation which was developed for cryogenic applications. It follows that

$$R_{t,\text{cond},i} = 60.7 \text{ K/W} = \frac{1}{4\pi k_i} \left(\frac{1}{r_2} - \frac{1}{r_3} \right) = \frac{1}{4\pi (0.000017 \text{ W/m}\cdot\text{K})} \left(\frac{1}{0.40 \text{ m}} - \frac{1}{r_3} \right)$$

which yields $r_3 = 0.4021 \text{ m}$. The minimum insulation thickness is therefore $\delta = (r_3 - r_2) = 2.1 \text{ mm}$.

COMMENTS: The heat loss could be reduced well below the maximum allowable by adding more insulation. Also, in view of weight restrictions associated with launching space vehicles, consideration should be given to fabricating the LOX container from a lighter material.

PROBLEM 3.59

KNOWN: Diameter and surface temperature of a spherical cryoprobe. Temperature of surrounding tissue and effective convection coefficient at interface between frozen and normal tissue.

FIND: Thickness of frozen tissue layer.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Negligible contact resistance between probe and frozen tissue, (3) Constant properties, (4) Negligible perfusion effects.

ANALYSIS: Performing an energy balance for a control surface about the phase front, it follows that

$$q_{\text{conv}} - q_{\text{cond}} = 0$$

Hence,

$$h \left(4\pi r_2^2 \right) (T_{\infty} - T_{s,2}) = \frac{T_{s,2} - T_{s,1}}{\left[(1/r_1) - (1/r_2) \right] / 4\pi k}$$

$$r_2^2 \left[(1/r_1) - (1/r_2) \right] = \frac{k (T_{s,2} - T_{s,1})}{h (T_{\infty} - T_{s,2})}$$

$$\left(\frac{r_2}{r_1} \right) \left[\left(\frac{r_2}{r_1} \right) - 1 \right] = \frac{k (T_{s,2} - T_{s,1})}{h r_1 (T_{\infty} - T_{s,2})} = \frac{1.5 \text{ W/m} \cdot \text{K}}{(50 \text{ W/m}^2 \cdot \text{K})(0.0015 \text{ m})} \left(\frac{30}{37} \right)$$

$$\left(\frac{r_2}{r_1} \right) \left[\left(\frac{r_2}{r_1} \right) - 1 \right] = 16.2$$

$$(r_2/r_1) = 4.56$$

It follows that $r_2 = 6.84 \text{ mm}$ and the thickness of the frozen tissue is

$$\delta = r_2 - r_1 = 5.34 \text{ mm}$$

<

PROBLEM 3.60

KNOWN: Inner diameter, wall thickness and thermal conductivity of spherical vessel containing heat generating medium. Inner surface temperature without insulation. Thickness and thermal conductivity of insulation. Ambient air temperature and convection coefficient.

FIND: (a) Thermal energy generated within vessel, (b) Inner surface temperature of vessel with insulation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional, radial conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Neglect radiation due to relatively low emissivity of stainless steel in part (a). In part (b), insulation resistance dominates.

ANALYSIS: (a) From an energy balance performed at an instant for a control surface about the pharmaceuticals, $\dot{E}_g = q$, in which case, without the insulation

$$\dot{E}_g = q = \frac{T_{s,1} - T_\infty}{\frac{1}{4\pi k_w} \left(\frac{1}{r_1} - \frac{1}{r_2} \right) + \frac{1}{4\pi r_2^2 h}} = \frac{(50 - 25)^\circ\text{C}}{\frac{1}{4\pi (17 \text{ W/m}\cdot\text{K})} \left(\frac{1}{0.50 \text{ m}} - \frac{1}{0.51 \text{ m}} \right) + \frac{1}{4\pi (0.51 \text{ m})^2 6 \text{ W/m}^2\cdot\text{K}}}$$

$$\dot{E}_g = q = \frac{25^\circ\text{C}}{(1.84 \times 10^{-4} + 5.10 \times 10^{-2}) \text{ K/W}} = 489 \text{ W} \quad <$$

(b) With the insulation,

$$T_{s,1} = T_\infty + q \left[\frac{1}{4\pi k_w} \left(\frac{1}{r_1} - \frac{1}{r_2} \right) + \frac{1}{4\pi k_i} \left(\frac{1}{r_2} - \frac{1}{r_3} \right) + \frac{1}{4\pi r_3^2 h} \right]$$

$$T_{s,1} = 25^\circ\text{C} + 489 \text{ W} \left[1.84 \times 10^{-4} + \frac{1}{4\pi (0.04)} \left(\frac{1}{0.51} - \frac{1}{0.53} \right) + \frac{1}{4\pi (0.53)^2 6} \right] \frac{\text{K}}{\text{W}}$$

$$T_{s,1} = 25^\circ\text{C} + 489 \text{ W} [1.84 \times 10^{-4} + 0.147 + 0.047] \frac{\text{K}}{\text{W}} = 120^\circ\text{C} \quad <$$

COMMENTS: The thermal resistance associated with the vessel wall is negligible, and without the insulation the dominant resistance is due to convection. The thermal resistance of the insulation is approximately three times that due to convection. Radiation may not be negligible, and would have the effect of increasing the heat loss rate (for fixed inner surface temperature) or decreasing the inner surface temperature (for fixed heat loss rate).

PROBLEM 3.61

KNOWN: Spherical tank of 1-m diameter containing an exothermic reaction and is at 200°C when the ambient air is at 25°C. Convection coefficient on outer surface is 20 W/m²·K.

FIND: Determine the thickness of urethane foam required to reduce the exterior temperature to 40°C. Determine the percentage reduction in the heat rate achieved using the insulation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial (spherical) conduction through the insulation, (3) Convection coefficient is the same for bare and insulated exterior surface, and (3) Negligible radiation exchange between the insulation outer surface and the ambient surroundings.

PROPERTIES: Table A-3, urethane, rigid foam (300 K): $k = 0.026$ W/m·K.

ANALYSIS: (a) The heat transfer situation for the heat rate from the tank can be represented by the thermal circuit shown above. The heat rate from the tank is

$$q = \frac{T_t - T_\infty}{R_{cd} + R_{cv}}$$

where the thermal resistances associated with conduction within the insulation (Eq. 3.36) and convection for the exterior surface, respectively, are

$$R_{cd} = \frac{(1/r_t - 1/r_o)}{4\pi k} = \frac{(1/0.5 - 1/r_o)}{4\pi \times 0.026 \text{ W/m} \cdot \text{K}} = \frac{(1/0.5 - 1/r_o)}{0.3267} \text{ K/W}$$

$$R_{cv} = \frac{1}{hA_s} = \frac{1}{4\pi r_o^2 h} = \frac{1}{4\pi \times 20 \text{ W/m}^2 \cdot \text{K} \times r_o^2} = 3.979 \times 10^{-3} r_o^{-2} \text{ K/W}$$

To determine the required insulation thickness so that $T_o = 40^\circ\text{C}$, perform an energy balance on the o-node.

$$\begin{aligned} \frac{T_t - T_o}{R_{cd}} + \frac{T_\infty - T_o}{R_{cv}} &= 0 \\ \frac{(200 - 40) \text{ K}}{(1/0.5 - 1/r_o)/0.3267 \text{ K/W}} + \frac{(25 - 40) \text{ K}}{3.979 \times 10^{-3} r_o^{-2} \text{ K/W}} &= 0 \\ r_o = 0.5135 \text{ m} \quad t = r_o - r_t = (0.5135 - 0.5000) \text{ m} &= 13.5 \text{ mm} \end{aligned} \quad <$$

From the rate equation, for the bare and insulated surfaces, respectively,

$$q_o = \frac{T_t - T_\infty}{1/4\pi r_t^2 h} = \frac{(200 - 25) \text{ K}}{0.01592 \text{ K/W}} = 10.99 \text{ kW}$$

$$q_{ins} = \frac{T_t - T_\infty}{R_{cd} + R_{cv}} = \frac{(200 - 25)}{(0.161 + 0.01592) \text{ K/W}} = 0.994 \text{ kW}$$

Hence, the percentage reduction in heat loss achieved with the insulation is,

$$\frac{q_{ins} - q_o}{q_o} \times 100 = -\frac{0.994 - 10.99}{10.99} \times 100 = 91\% \quad <$$

PROBLEM 3.62

KNOWN: Dimensions and materials used for composite spherical shell. Heat generation associated with stored material.

FIND: Inner surface temperature, T_1 , of lead (proposal is flawed if this temperature exceeds the melting point).

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) Constant properties at 300K, (4) Negligible contact resistance.

PROPERTIES: Table A-1, Lead: $k = 35.3 \text{ W/m}\cdot\text{K}$, MP = 601K; St.St.: $15.1 \text{ W/m}\cdot\text{K}$.

ANALYSIS: From the thermal circuit, it follows that

$$q = \frac{T_1 - T_\infty}{R_{\text{tot}}} = \dot{q} \left[\frac{4}{3} \pi r_1^3 \right]$$

Evaluate the thermal resistances,

$$R_{\text{Pb}} = \left[1 / (4\pi \times 35.3 \text{ W/m}\cdot\text{K}) \right] \left[\frac{1}{0.25\text{m}} - \frac{1}{0.30\text{m}} \right] = 0.00150 \text{ K/W}$$

$$R_{\text{St.St.}} = \left[1 / (4\pi \times 15.1 \text{ W/m}\cdot\text{K}) \right] \left[\frac{1}{0.30\text{m}} - \frac{1}{0.31\text{m}} \right] = 0.000567 \text{ K/W}$$

$$R_{\text{conv}} = \left[1 / (4\pi \times 0.31^2 \text{ m}^2 \times 500 \text{ W/m}^2 \cdot \text{K}) \right] = 0.00166 \text{ K/W}$$

$$R_{\text{tot}} = 0.00372 \text{ K/W.}$$

The heat rate is $q = 5 \times 10^5 \text{ W/m}^3 \left(\frac{4\pi}{3} \right) (0.25\text{m})^3 = 32,725 \text{ W}$. The inner surface temperature is

$$T_1 = T_\infty + R_{\text{tot}} q = 283\text{K} + 0.00372\text{K/W} (32,725 \text{ W})$$

$$T_1 = 405 \text{ K} < \text{MP} = 601\text{K.}$$

<

Hence, from the thermal standpoint, the proposal is adequate.

COMMENTS: In fabrication, attention should be given to maintaining a good thermal contact. A protective outer coating should be applied to prevent long term corrosion of the stainless steel.

PROBLEM 3.63

KNOWN: Dimensions and materials of composite (lead and stainless steel) spherical shell used to store radioactive wastes with constant heat generation. Range of convection coefficients h available for cooling.

FIND: (a) Variation of maximum lead temperature with h . Minimum allowable value of h to maintain maximum lead temperature at or below 500 K. (b) Effect of outer radius of stainless steel shell on maximum lead temperature for $h = 300, 500$ and $1000 \text{ W/m}^2\cdot\text{K}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) Constant properties at 300 K, (4) Negligible contact resistance.

PROPERTIES: Table A-1, Lead: $k = 35.3 \text{ W/m}\cdot\text{K}$, SS.: $15.1 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) From the schematic, the maximum lead temperature T_1 corresponds to $r = r_1$, and from the thermal circuit, it may be expressed as

$$T_1 = T_\infty + R_{\text{tot}} q$$

where $q = \dot{q} \left(\frac{4}{3} \right) \pi r_1^3 = 5 \times 10^5 \text{ W/m}^3 \left(\frac{4}{3} \right) \pi (0.25 \text{ m})^3 = 32,725 \text{ W}$. The total thermal resistance is

$$R_{\text{tot}} = R_{\text{cond,Pb}} + R_{\text{cond,St.St.}} + R_{\text{conv}}$$

where expressions for the component resistances are provided in the schematic. Using the *Resistance Network* model and *Thermal Resistance* tool pad of IHT, the following result is obtained for the variation of T_1 with h .

Continued...

PROBLEM 3.63 (Cont.)

To maintain T_1 below 500 K, the convection coefficient must be maintained at

$$h \geq 181 \text{ W/m}^2\cdot\text{K}$$

(b) The effect of varying the outer shell radius over the range $0.3 \leq r_3 \leq 0.5$ m is shown below.

For $h = 300, 500$ and $1000 \text{ W/m}^2\cdot\text{K}$, the maximum allowable values of the outer radius are $r_3 = 0.365, 0.391$ and 0.408 m, respectively.

COMMENTS: For a maximum allowable value of $T_1 = 500$ K, the maximum allowable value of the total thermal resistance is $R_{\text{tot}} = (T_1 - T_\infty)/q$, or $R_{\text{tot}} = (500 - 283)\text{K}/32,725 \text{ W} = 0.00663 \text{ K/W}$. Hence, any increase in $R_{\text{cond,St,St}}$ due to increasing r_3 must be accompanied by an equivalent reduction in R_{conv} .

PROBLEM 3.64

KNOWN: Representation of the eye with a contact lens as a composite spherical system subjected to convection processes at the boundaries.

FIND: (a) Thermal circuits with and without contact lens in place, (b) Heat loss from anterior chamber for both cases, and (c) Implications of the heat loss calculations.

SCHEMATIC:

$$r_1 = 10.2 \text{ mm} \quad k_1 = 0.35 \text{ W/m} \cdot \text{K}$$

$$r_2 = 12.7 \text{ mm} \quad k_2 = 0.80 \text{ W/m} \cdot \text{K}$$

$$r_3 = 16.5 \text{ mm}$$

$$T_{\infty,i} = 37^\circ \text{C} \quad h_i = 12 \text{ W/m}^2 \cdot \text{K}$$

$$T_{\infty,o} = 21^\circ \text{C} \quad h_o = 6 \text{ W/m}^2 \cdot \text{K}$$

ASSUMPTIONS: (1) Steady-state conditions, (2) Eye is represented as 1/3 sphere, (3) Convection coefficient, h_o , unchanged with or without lens present, (4) Negligible contact resistance.

ANALYSIS: (a) Using Eqs. 3.9 and 3.36 to express the resistance terms, the thermal circuits are:

Without lens:

$$\begin{array}{c} T_{\infty,i} \\ \downarrow q_{wo} \\ \text{---} \frac{3}{3h_i 4\pi r_1^2} \text{---} \frac{3}{4\pi k_1 (\frac{1}{r_1} - \frac{1}{r_2})} \text{---} \frac{3}{3h_o 4\pi r_2^2} \text{---} T_{\infty,o} \end{array} \quad <$$

With lens:

$$\begin{array}{c} T_{\infty,i} \\ \downarrow q_w \\ \text{---} \frac{3}{3h_i 4\pi r_1^2} \text{---} \frac{3}{4\pi k_1 (\frac{1}{r_1} - \frac{1}{r_2})} \text{---} \frac{3}{4\pi k_2 (\frac{1}{r_2} - \frac{1}{r_3})} \text{---} \frac{3}{3h_o 4\pi r_3^2} \text{---} T_{\infty,o} \end{array} \quad <$$

(b) The heat losses for both cases can be determined as $q = (T_{\infty,i} - T_{\infty,o})/R_t$, where R_t is the thermal resistance from the above circuits.

$$\begin{aligned} \text{Without lens: } R_{t,wo} &= \frac{3}{12 \text{ W/m}^2 \cdot \text{K} 4\pi (10.2 \times 10^{-3} \text{ m})^2} + \frac{3}{4\pi \times 0.35 \text{ W/m} \cdot \text{K} \left[\frac{1}{10.2} - \frac{1}{12.7} \right] \frac{1}{10^{-3} \text{ m}}} \\ &+ \frac{3}{6 \text{ W/m}^2 \cdot \text{K} 4\pi (12.7 \times 10^{-3} \text{ m})^2} = 191.2 \text{ K/W} + 13.2 \text{ K/W} + 246.7 \text{ K/W} = 451.1 \text{ K/W} \end{aligned}$$

$$\begin{aligned} \text{With lens: } R_{t,w} &= 191.2 \text{ K/W} + 13.2 \text{ K/W} + \frac{3}{4\pi \times 0.80 \text{ W/m} \cdot \text{K} \left[\frac{1}{12.7} - \frac{1}{16.5} \right] \frac{1}{10^{-3} \text{ m}}} \\ &+ \frac{3}{6 \text{ W/m}^2 \cdot \text{K} 4\pi (16.5 \times 10^{-3} \text{ m})^2} = 191.2 \text{ K/W} + 13.2 \text{ K/W} + 5.41 \text{ K/W} + 146.2 \text{ K/W} = 356.0 \text{ K/W} \end{aligned}$$

Hence the heat loss rates from the anterior chamber are

$$\text{Without lens: } q_{wo} = (37 - 21)^\circ \text{C} / 451.1 \text{ K/W} = 35.5 \text{ mW} \quad <$$

$$\text{With lens: } q_w = (37 - 21)^\circ \text{C} / 356.0 \text{ K/W} = 44.9 \text{ mW} \quad <$$

(c) The heat loss from the anterior chamber increases by approximately 20% when the contact lens is in place, implying that the outer radius, r_3 , is less than the critical radius.

PROBLEM 3.65

KNOWN: Thermal conductivity and inner and outer radii of a hollow sphere subjected to a uniform heat flux at its outer surface and maintained at a uniform temperature on the inner surface.

FIND: (a) Expression for radial temperature distribution, (b) Heat flux required to maintain prescribed surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) No generation, (4) Constant properties.

ANALYSIS: (a) For the assumptions, the temperature distribution may be obtained by integrating Fourier's law, Eq. 3.33. That is,

$$\frac{q_r}{4\pi} \int_{r_1}^r \frac{dr}{r^2} = -k \int_{T_{s,1}}^T dT \quad \text{or} \quad -\frac{q_r}{4\pi} \frac{1}{r} \bigg|_{r_1}^r = -k(T - T_{s,1}).$$

Hence,

$$T(r) = T_{s,1} + \frac{q_r}{4\pi k} \left[\frac{1}{r} - \frac{1}{r_1} \right]$$

or, with $q_2'' = q_r / 4\pi r_2^2$,

$$T(r) = T_{s,1} + \frac{q_2'' r_2^2}{k} \left[\frac{1}{r} - \frac{1}{r_1} \right] \quad <$$

(b) Applying the above result at r_2 ,

$$q_2'' = \frac{k(T_{s,2} - T_{s,1})}{r_2^2 \left[\frac{1}{r_2} - \frac{1}{r_1} \right]} = \frac{10 \text{ W/m}\cdot\text{K} (50 - 20)^\circ\text{C}}{(0.1 \text{ m})^2 \left[\frac{1}{0.1} - \frac{1}{0.05} \right] \frac{1}{\text{m}}} = -3000 \text{ W/m}^2. \quad <$$

COMMENTS: (1) The desired temperature distribution could also be obtained by solving the appropriate form of the heat equation,

$$\frac{d}{dr} \left[r^2 \frac{dT}{dr} \right] = 0$$

and applying the boundary conditions $T(r_1) = T_{s,1}$ and $-k \frac{dT}{dr} \bigg|_{r_2} = q_2''$.

(2) The negative sign on q_2'' implies heat transfer in the negative r direction.

PROBLEM 3.66

KNOWN: Volumetric heat generation occurring within the cavity of a spherical shell of prescribed dimensions. Convection conditions at outer surface.

FIND: Expression for steady-state temperature distribution in shell.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Steady-state conditions, (3) Constant properties, (4) Uniform generation within the shell cavity, (5) Negligible radiation.

ANALYSIS: For the prescribed conditions, the appropriate form of the heat equation is

$$\frac{d}{dr} \left[r^2 \frac{dT}{dr} \right] = 0$$

Integrate twice to obtain,

$$r^2 \frac{dT}{dr} = C_1 \quad \text{and} \quad T = -\frac{C_1}{r} + C_2. \quad (1,2)$$

The boundary conditions may be obtained from energy balances at the inner and outer surfaces. At the inner surface (r_i),

$$\dot{E}_g = \dot{q} \left(4/3 \pi r_i^3 \right) = q_{\text{cond},i} = -k \left(4 \pi r_i^2 \right) \left. \frac{dT}{dr} \right|_{r_i} \quad \left. \frac{dT}{dr} \right|_{r_i} = -\dot{q} r_i / 3k. \quad (3)$$

At the outer surface (r_o),

$$q_{\text{cond},o} = -k 4 \pi r_o^2 \left. \frac{dT}{dr} \right|_{r_o} = q_{\text{conv}} = h 4 \pi r_o^2 \left[T(r_o) - T_\infty \right] \\ \left. \frac{dT}{dr} \right|_{r_o} = -(h/k) \left[T(r_o) - T_\infty \right]. \quad (4)$$

From Eqs. (1) and (3), $C_1 = -\dot{q} r_i^3 / 3k$. From Eqs. (1), (2) and (4)

$$-\frac{\dot{q} r_i^3}{3k r_o^2} = -\left[\frac{h}{k} \right] \left[\frac{\dot{q} r_i^3}{3r_o k} + C_2 - T_\infty \right] \\ C_2 = \frac{\dot{q} r_i^3}{3h r_o^2} - \frac{\dot{q} r_i^3}{3r_o k} + T_\infty.$$

Hence, the temperature distribution is

$$T = \frac{\dot{q} r_i^3}{3k} \left[\frac{1}{r} - \frac{1}{r_o} \right] + \frac{\dot{q} r_i^3}{3h r_o^2} + T_\infty. \quad <$$

COMMENTS: Note that $\dot{E}_g = q_{\text{cond},i} = q_{\text{cond},o} = q_{\text{conv}}$.

PROBLEM 3.67

KNOWN: Spherical tank of 3-m diameter containing LP gas at -60°C with 250 mm thickness of insulation having thermal conductivity of $0.06\text{ W/m}\cdot\text{K}$. Ambient air temperature and convection coefficient on the outer surface are 20°C and $6\text{ W/m}^2\cdot\text{K}$, respectively.

FIND: (a) Determine the radial position in the insulation at which the temperature is 0°C and (b) If the insulation is pervious to moisture, what conclusions can be reached about ice formation? What effect will ice formation have on the heat gain? How can this situation be avoided?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial (spherical) conduction through the insulation, and (3) Negligible radiation exchange between the insulation outer surface and the ambient surroundings, (4) Inner surface of insulation at T_t .

ANALYSIS: (a) The heat transfer situation can be represented by the thermal circuit shown above. The heat gain to the tank is

$$q = \frac{T_\infty - T_t}{R_{\text{ins}} + R_{\text{cv}}} = \frac{[20 - (-60)]\text{ K}}{(0.1263 + 4.33 \times 10^{-3})\text{ K/W}} = 612.4\text{ W}$$

where the thermal resistances for the insulation (see Table 3.3) and the convection process on the outer surface are, respectively,

$$R_{\text{ins}} = \frac{1/r_i - 1/r_o}{4\pi k} = \frac{(1/1.50 - 1/1.75)\text{ m}^{-1}}{4\pi \times 0.06\text{ W/m}\cdot\text{K}} = 0.1263\text{ K/W}$$

$$R_{\text{cv}} = \frac{1}{hA_s} = \frac{1}{h4\pi r_o^2} = \frac{1}{6\text{ W/m}^2\cdot\text{K} \times 4\pi (1.75\text{ m})^2} = 4.33 \times 10^{-3}\text{ K/W}$$

To determine the location within the insulation where $T_{\text{oo}}(r_{\text{oo}}) = 0^\circ\text{C}$, use the conduction rate equation, Eq. 3.35,

$$q = \frac{4\pi k (T_{\text{oo}} - T_t)}{(1/r_i - 1/r_{\text{oo}})} \quad r_{\text{oo}} = \left[\frac{1}{r_i} - \frac{4\pi k (T_{\text{oo}} - T_t)}{q} \right]^{-1}$$

and substituting numerical values, find

$$r_{\text{oo}} = \left[\frac{1}{1.5\text{ m}} - \frac{4\pi \times 0.06\text{ W/m}\cdot\text{K} (0 - (-60))\text{ K}}{612.4\text{ W}} \right]^{-1} = 1.687\text{ m} \quad <$$

(b) With $r_{\text{oo}} = 1.687\text{ m}$, we'd expect the region of the insulation $r_i \leq r \leq r_{\text{oo}}$ to be filled with ice formations if the insulation is pervious to water vapor. The effect of the ice formation is to substantially increase the heat gain since k_{ice} is nearly twice that of k_{ins} , and the ice region is of thickness $(1.687 - 1.50)\text{ m} = 187\text{ mm}$. To avoid ice formation, a vapor barrier should be installed at a radius larger than r_{oo} .

PROBLEM 3.68

KNOWN: Radius and heat dissipation of a hemispherical source embedded in a substrate of prescribed thermal conductivity. Source and substrate boundary conditions.

FIND: Substrate temperature distribution and surface temperature of heat source.

SCHEMATIC:

ASSUMPTIONS: (1) Top surface is adiabatic. Hence, hemispherical source in semi-infinite medium is equivalent to spherical source in infinite medium (with $q = 8 \text{ W}$) and heat transfer is one-dimensional in the radial direction, (2) Steady-state conditions, (3) Constant properties, (4) No generation.

ANALYSIS: Heat equation reduces to

$$\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{dT}{dr} \right) = 0 \quad r^2 dT/dr = C_1$$

$$T(r) = -C_1 / r + C_2.$$

Boundary conditions:

$$T(\infty) = T_\infty \quad T(r_0) = T_s$$

Hence, $C_2 = T_\infty$ and

$$T_s = -C_1 / r_0 + T_\infty \quad \text{and} \quad C_1 = r_0 (T_\infty - T_s).$$

The temperature distribution has the form

$$T(r) = T_\infty + (T_s - T_\infty) r_0 / r$$

and the heat rate is

$$q = -kA dT/dr = -k2\pi r^2 \left[-(T_s - T_\infty) r_0 / r^2 \right] = k2\pi r_0 (T_s - T_\infty)$$

It follows that

$$T_s - T_\infty = \frac{q}{k2\pi r_0} = \frac{4 \text{ W}}{125 \text{ W/m} \cdot \text{K} \cdot 2\pi (10^{-4} \text{ m})} = 50.9^\circ \text{C}$$

$$T_s = 77.9^\circ \text{C}.$$

COMMENTS: For the semi-infinite (or infinite) medium approximation to be valid, the substrate dimensions must be much larger than those of the transistor.

PROBLEM 3.69

KNOWN: Critical and normal tissue temperatures. Radius of spherical heat source and radius of tissue to be maintained above the critical temperature. Tissue thermal conductivity.

FIND: General expression for radial temperature distribution in tissue. Heat rate required to maintain prescribed thermal conditions.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Constant k , (3) Negligible contact resistance.

ANALYSIS: The appropriate form of the heat equation is

$$\frac{1}{r^2} \frac{d}{dr} \left(r \frac{dT}{dr} \right) = 0$$

Integrating twice,

$$\frac{dT}{dr} = \frac{C_1}{r^2}$$

$$T(r) = -\frac{C_1}{r} + C_2$$

Since $T \rightarrow T_b$ as $r \rightarrow \infty$, $C_2 = T_b$. At $r = r_o$, $q = -k \left(4\pi r_o^2 \right) dT/dr \Big|_{r_o} = -4\pi k r_o^2 C_1 / r_o^2 = -4\pi k C_1$.

Hence, $C_1 = -q/4\pi k$ and the temperature distribution is

$$T(r) = \frac{q}{4\pi k r} + T_b \quad <$$

It follows that

$$q = 4\pi k r [T(r) - T_b]$$

Applying this result at $r = r_c$,

$$q = 4\pi (0.5 \text{ W/m}\cdot\text{K}) (0.005 \text{ m}) (42 - 37)^\circ\text{C} = 0.157 \text{ W} \quad <$$

COMMENTS: At $r_o = 0.0005 \text{ m}$, $T(r_o) = [q/(4\pi k r_o)] + T_b = 87^\circ\text{C}$. Proximity of this temperature to the boiling point of water suggests the need to operate at a lower power dissipation level.

PROBLEM 3.70

KNOWN: Cylindrical and spherical shells with uniform heat generation and surface temperatures.

FIND: Radial distributions of temperature, heat flux and heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Uniform heat generation, (3) Constant k .

ANALYSIS: (a) For the *cylindrical shell*, the appropriate form of the heat equation is

$$\frac{1}{r} \frac{d}{dr} \left(r \frac{dT}{dr} \right) + \frac{\dot{q}}{k} = 0$$

The general solution is

$$T(r) = -\frac{\dot{q}}{4k} r^2 + C_1 \ln r + C_2$$

Applying the boundary conditions, it follows that

$$T(r_1) = T_{s,1} = -\frac{\dot{q}}{4k} r_1^2 + C_1 \ln r_1 + C_2$$

$$T(r_2) = T_{s,2} = -\frac{\dot{q}}{4k} r_2^2 + C_1 \ln r_2 + C_2$$

which may be solved for

$$C_1 = \left[\left(\frac{\dot{q}}{4k} \right) (r_2^2 - r_1^2) + (T_{s,2} - T_{s,1}) \right] / \ln(r_2/r_1)$$

$$C_2 = T_{s,2} + \left(\frac{\dot{q}}{4k} \right) r_2^2 - C_1 \ln r_2$$

Hence,

$$T(r) = T_{s,2} + \left(\frac{\dot{q}}{4k} \right) (r_2^2 - r^2) + \left[\left(\frac{\dot{q}}{4k} \right) (r_2^2 - r_1^2) + (T_{s,2} - T_{s,1}) \right] \frac{\ln(r/r_2)}{\ln(r_2/r_1)} \quad <$$

With $q'' = -k dT/dr$, the heat flux distribution is

$$q''(r) = \frac{\dot{q}}{2} r - \frac{k \left[\left(\frac{\dot{q}}{4k} \right) (r_2^2 - r_1^2) + (T_{s,2} - T_{s,1}) \right]}{r \ln(r_2/r_1)} \quad <$$

Continued...

PROBLEM 3.70 (Cont.)

Similarly, with $q = q'' A(r) = q'' (2\pi rL)$, the heat rate distribution is

$$q(r) = \pi L \dot{q} r^2 - \frac{2\pi L k \left[(\dot{q}/4k)(r_2^2 - r_1^2) + (T_{s,2} - T_{s,1}) \right]}{\ln(r_2/r_1)} \quad <$$

(b) For the *spherical shell*, the heat equation and general solution are

$$\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{dT}{dr} \right) + \frac{\dot{q}}{k} = 0$$

$$T(r) = -(\dot{q}/6k)r^2 - C_1/r + C_2$$

Applying the boundary conditions, it follows that

$$T(r_1) = T_{s,1} = -(\dot{q}/6k)r_1^2 - C_1/r_1 + C_2$$

$$T(r_2) = T_{s,2} = -(\dot{q}/6k)r_2^2 - C_1/r_2 + C_2$$

Hence,

$$C_1 = \left[(\dot{q}/6k)(r_2^2 - r_1^2) + (T_{s,2} - T_{s,1}) \right] / \left[(1/r_1) - (1/r_2) \right]$$

$$C_2 = T_{s,2} + (\dot{q}/6k)r_2^2 + C_1/r_2$$

and

$$T(r) = T_{s,2} + (\dot{q}/6k)(r_2^2 - r^2) - \left[(\dot{q}/6k)(r_2^2 - r_1^2) + (T_{s,2} - T_{s,1}) \right] \frac{(1/r) - (1/r_2)}{(1/r_1) - (1/r_2)} \quad <$$

With $q''(r) = -k dT/dr$, the heat flux distribution is

$$q''(r) = \frac{\dot{q}}{3} r - \frac{\left[(\dot{q}/6)(r_2^2 - r_1^2) + k(T_{s,2} - T_{s,1}) \right]}{(1/r_1) - (1/r_2)} \frac{1}{r^2} \quad <$$

and, with $q = q'' (4\pi r^2)$, the heat rate distribution is

$$q(r) = \frac{4\pi \dot{q}}{3} r^3 - \frac{4\pi \left[(\dot{q}/6)(r_2^2 - r_1^2) + k(T_{s,2} - T_{s,1}) \right]}{(1/r_1) - (1/r_2)} \quad <$$

PROBLEM 3.71

KNOWN: Temperature distribution in a composite wall.

FIND: (a) Relative magnitudes of interfacial heat fluxes, (b) Relative magnitudes of thermal conductivities, and (c) Heat flux as a function of distance x .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties.

ANALYSIS: (a) For the prescribed conditions (one-dimensional, steady-state, constant k), the parabolic temperature distribution in C implies the existence of heat generation. Hence, since dT/dx increases with decreasing x , the heat flux in C increases with decreasing x . Hence,

$$q''_3 > q''_4$$

However, the linear temperature distributions in A and B indicate no generation, in which case

$$q''_2 = q''_3$$

(b) Since conservation of energy requires that $q''_{3,B} = q''_{3,C}$ and $dT/dx)_B < dT/dx)_C$, it follows from Fourier's law that

$$k_B > k_C.$$

Similarly, since $q''_{2,A} = q''_{2,B}$ and $dT/dx)_A > dT/dx)_B$, it follows that

$$k_A < k_B.$$

(c) It follows that the flux distribution appears as shown below.

COMMENTS: Note that, with $dT/dx)_{4,C} = 0$, the interface at 4 is adiabatic.

PROBLEM 3.72

KNOWN: Plane wall with internal heat generation which is insulated at the inner surface and subjected to a convection process at the outer surface.

FIND: Maximum temperature in the wall.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with uniform volumetric heat generation, (3) Inner surface is adiabatic.

ANALYSIS: From Eq. 3.42, the temperature at the inner surface is given by Eq. 3.43 and is the maximum temperature within the wall,

$$T_0 = \dot{q}L^2 / 2k + T_s.$$

The outer surface temperature follows from Eq. 3.46,

$$T_s = T_\infty + \dot{q}L/h$$

$$T_s = 92^\circ\text{C} + 0.3 \times 10^6 \frac{\text{W}}{\text{m}^3} \times 0.1\text{m} / 500\text{W/m}^2 \cdot \text{K} = 92^\circ\text{C} + 60^\circ\text{C} = 152^\circ\text{C}.$$

It follows that

$$T_0 = 0.3 \times 10^6 \text{W/m}^3 \times (0.1\text{m})^2 / 2 \times 25\text{W/m} \cdot \text{K} + 152^\circ\text{C}$$

$$T_0 = 60^\circ\text{C} + 152^\circ\text{C} = 212^\circ\text{C}.$$

<

COMMENTS: The heat flux leaving the wall can be determined from knowledge of h , T_s and T_∞ using Newton's law of cooling.

$$q''_{\text{conv}} = h(T_s - T_\infty) = 500\text{W/m}^2 \cdot \text{K} (152 - 92)^\circ\text{C} = 30\text{kW/m}^2.$$

This same result can be determined from an energy balance on the entire wall, which has the form

$$\dot{E}_g - \dot{E}_{\text{out}} = 0$$

where

$$\dot{E}_g = \dot{q}AL \quad \text{and} \quad \dot{E}_{\text{out}} = q''_{\text{conv}} \cdot A.$$

Hence,

$$q''_{\text{conv}} = \dot{q}L = 0.3 \times 10^6 \text{W/m}^3 \times 0.1\text{m} = 30\text{kW/m}^2.$$

PROBLEM 3.73

KNOWN: Composite wall with outer surfaces exposed to convection process.

FIND: (a) Volumetric heat generation and thermal conductivity for material B required for special conditions, (b) Plot of temperature distribution, (c) T_1 and T_2 , as well as temperature distributions corresponding to loss of coolant condition where $h = 0$ on surface A.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, one-dimensional heat transfer, (2) Negligible contact resistance at interfaces, (3) Uniform generation in B; zero in A and C.

ANALYSIS: (a) From an energy balance on wall B,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}$$

$$-q_1'' - q_2'' + 2\dot{q}L_B = 0$$

$$\dot{q}_B = (q_1'' + q_2'')/2L_B \quad (1)$$

To determine the heat fluxes, q_1'' and q_2'' , construct thermal circuits for A and C:

$$q_1'' = (T_1 - T_\infty)/(1/h + L_A/k_A)$$

$$q_1'' = (261 - 25)^\circ\text{C} / \left(\frac{1}{1000 \text{ W/m}^2 \cdot \text{K}} + \frac{0.030 \text{ m}}{25 \text{ W/m} \cdot \text{K}} \right)$$

$$q_1'' = 236^\circ\text{C} / (0.001 + 0.0012) \text{ m}^2 \cdot \text{K/W}$$

$$q_1'' = 107,273 \text{ W/m}^2$$

$$q_2'' = (T_2 - T_\infty)/(L_C/k_C + 1/h)$$

$$q_2'' = (211 - 25)^\circ\text{C} / \left(\frac{0.020 \text{ m}}{50 \text{ W/m} \cdot \text{K}} + \frac{1}{1000 \text{ W/m}^2 \cdot \text{K}} \right)$$

$$q_2'' = 186^\circ\text{C} / (0.0004 + 0.001) \text{ m}^2 \cdot \text{K/W}$$

$$q_2'' = 132,857 \text{ W/m}^2$$

Using the values for q_1'' and q_2'' in Eq. (1), find

$$\dot{q}_B = (106,818 + 132,143 \text{ W/m}^2) / 2 \times 0.030 \text{ m} = 4.00 \times 10^6 \text{ W/m}^3$$

<

To determine k_B , use the general form of the temperature (Eq. 3.40) and heat flux distributions in wall B,

$$T(x) = -\frac{\dot{q}_B}{2k_B}x^2 + C_1x + C_2 \quad q_x''(x) = -k_B \left[-\frac{\dot{q}_B}{k_B}x + C_1 \right] \quad (2,3)$$

there are 3 unknowns, C_1 , C_2 and k_B , which can be evaluated using three conditions,

Continued...

PROBLEM 3.73 (Cont.)

$$T(-L_B) = T_1 = -\frac{\dot{q}_B}{2k_B}(-L_B)^2 - C_1 L_B + C_2 \quad \text{where } T_1 = 261^\circ\text{C} \quad (4)$$

$$T(+L_B) = T_2 = -\frac{\dot{q}_B}{2k_B}(+L_B)^2 + C_1 L_B + C_2 \quad \text{where } T_2 = 211^\circ\text{C} \quad (5)$$

$$q_x''(-L_B) = -q_1'' = -k_B \left[-\frac{\dot{q}_B}{k_B}(-L_B) + C_1 \right] \quad \text{where } q_1'' = 107,273 \text{ W/m}^2 \quad (6)$$

Using IHT to solve Eqs. (4), (5) and (6) simultaneously with $\dot{q}_B = 4.00 \times 10^6 \text{ W/m}^3$, find

$$k_B = 15.3 \text{ W/m} \cdot \text{K}$$

(b) Following the method of analysis in the *IHT Example 3.6, User-Defined Functions*, the temperature distribution is shown in the plot below. The important features are (1) Distribution is quadratic in B, but non-symmetrical; linear in A and C; (2) Because thermal conductivities of the materials are different, discontinuities exist at each interface; (3) By comparison of gradients at $x = -L_B$ and $+L_B$, find $q_2'' > q_1''$.

(c) Using the same method of analysis as for Part (c), the temperature distribution is shown in the plot below when $h = 0$ on the surface of A. Since the left boundary is adiabatic, material A will be isothermal at T_1 . Find

$$T_1 = 835^\circ\text{C} \quad T_2 = 360^\circ\text{C}$$

PROBLEM 3.74

KNOWN: Dimensions and properties of a composite wall exposed to convective or insulated conditions.

FIND: (a) Maximum wall temperature for left face insulated and right face convectively cooled. (b) Sketch the steady-state temperature distribution of part (a). (c) Sketch the steady-state temperature distribution with reversed boundary conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Uniform volumetric energy generation.

ANALYSIS:

(a) The heat flux through materials B and C is constant and is

$$q'' = \dot{q}_A(L_A) = 5000 \text{ W/m}^2 \times 0.02 \text{ m} = 100 \text{ W/m}^2$$

The thermal resistance network that spans from $x = L_A$ to the coolant is

The thermal resistances are:

$$R''_{tc} = 0.01 \text{ m}^2 \cdot \text{K/W}$$

$$R''_{tcond,B} = \frac{L_B}{k_B} = \frac{0.013 \text{ m}}{0.13 \text{ W/m}\cdot\text{K}} = 0.1 \frac{\text{m}^2 \cdot \text{K}}{\text{W}}$$

$$R''_{tcond,C} = \frac{L_C}{k_C} = \frac{0.020 \text{ m}}{0.50 \text{ W/m}\cdot\text{K}} = 0.04 \frac{\text{m}^2 \cdot \text{K}}{\text{W}}$$

Continued...

PROBLEM 3.74 (Cont.)

$$R''_{t,conv} = \frac{1}{h} = \frac{1}{10 \text{ W/m}^2 \cdot \text{K}} = 0.1 \frac{\text{m}^2 \cdot \text{K}}{\text{W}}$$

The total thermal resistance is

$$R''_{t,tot} = (0.01 + 0.1 + 0.01 + 0.04 + 0.1) = 0.26 \frac{\text{m}^2 \cdot \text{K}}{\text{W}}$$

Therefore,

$$T_A(x=L_A) = q''(R''_{t,tot}) + T_\infty = 100 \text{ W/m}^2 \times 0.26 \frac{\text{m}^2 \cdot \text{K}}{\text{W}} + 20^\circ\text{C} = 46^\circ\text{C}$$

The maximum temperature occurs at $x = 0$ and may be evaluated by using Eq. 3.43 as follows

$$T_A(x=0) = T_A(x=L_A) + \frac{\dot{q}_A L_A^2}{2k_A} = 46^\circ\text{C} + \frac{5000 \text{ W/m}^3 \times (0.02 \text{ m})^2}{2 \times 0.24 \text{ W/m} \cdot \text{K}}$$

$$T_A(x=0) = T_{\max} = 50.2^\circ\text{C}$$

<

(b) To sketch the temperature distribution, we begin by evaluating the temperatures shown in the thermal resistance network. Working from the coolant side,

$$T_s = T_\infty + q''(R''_{t,conv}) = 20^\circ\text{C} + 100 \text{ W/m}^2 \times 0.1 \text{ m}^2 \cdot \text{K/W} = 30^\circ\text{C}$$

$$T_C(x=L_A+L_B) = T_s + q''(R''_{t,cond,C}) = 30^\circ\text{C} + 100 \text{ W/m}^2 \times 0.04 \text{ m}^2 \cdot \text{K/W} = 34^\circ\text{C}$$

$$T_B(x=L_A+L_B) = T_C(x=L_A+L_B) + q''(R''_{t,c}) = 34^\circ\text{C} + 100 \text{ W/m}^2 \times 0.01 \frac{\text{m}^2 \cdot \text{K}}{\text{W}} = 35^\circ\text{C}$$

$$T_B(x=L_A) = T_B(x=L_A+L_B) + q''(R''_{t,cond,B}) = 35^\circ\text{C} + 100 \text{ W/m}^2 \times 0.1 \text{ m}^2 \cdot \text{K/W} = 45^\circ\text{C}$$

and from part (a), $T_A(x=L_A) = 46^\circ\text{C}$. The temperature distribution is sketched below.

(c) For case 2, the heat flux in the range $0 \leq x \leq L_A + L_B$ is zero. Hence the boundary at $x = L_A + L_B$ acts as an insulated surface for material C. Therefore, from Eq. 3.43,

$$T_{\max} = T_c(x=L_A+L_B) = T_s + \frac{\dot{q}_C L_C^2}{2k_C} = 30^\circ\text{C} + \frac{5000 \text{ W/m}^3 \times (0.02\text{m})^2}{2 \times 0.50 \text{ W/m} \cdot \text{K}} = 32^\circ\text{C}$$

The temperature distribution is sketched below.

Continued...

PROBLEM 3.74 (Cont.)

Case 1 temperature distribution.

Case 2 temperature distribution.

COMMENTS: If the heat flux due to conduction in the x -direction is zero, the temperature gradient, dT/dx , must be zero. This is a direct consequence of Fourier's law, and holds under all conditions.

PROBLEM 3.75

KNOWN: Composite wall of materials A and B. Wall of material A has uniform generation, while wall B has no generation. The inner wall of material A is insulated, while the outer surface of material B experiences convection cooling. Thermal contact resistance between the materials is

$R''_{t,c} = 10^{-4} \text{ m}^2 \cdot \text{K} / \text{W}$. See Ex. 3.6 that considers the case without contact resistance.

FIND: Compute and plot the temperature distribution in the composite wall.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with constant properties, and (3) Inner surface of material A is adiabatic.

ANALYSIS: From the analysis of Ex. 3.7, we know the temperature distribution in material A is parabolic with zero slope at the inner boundary, and that the distribution in material B is linear. At the interface between the two materials, $x = L_A$, the temperature distribution will show a discontinuity.

$$T_A(x) = \frac{\dot{q} L_A^2}{2k_A} \left(1 - \frac{x^2}{L_A^2} \right) + T_{1A} \quad 0 \leq x \leq L_A$$

$$T_B(x) = T_{1B} - (T_{1B} - T_2) \frac{x - L_A}{L_B} \quad L_A \leq x \leq L_A + L_B$$

Considering the thermal circuit above (see also Ex. 3.7) including the thermal contact resistance,

$$\dot{q}'' = \dot{q} L_A = \frac{T_{1A} - T_\infty}{R''_{\text{tot}}} = \frac{T_{1B} - T_\infty}{R''_{\text{cond},B} + R''_{\text{conv}}} = \frac{T_2 - T_\infty}{R''_{\text{conv}}}$$

find $T_A(0) = 147.5^\circ\text{C}$, $T_{1A} = 122.5^\circ\text{C}$, $T_{1B} = 115^\circ\text{C}$, and $T_2 = 105^\circ\text{C}$. Using the foregoing equations in IHT, the temperature distributions for each of the materials can be calculated and are plotted on the graph below.

COMMENTS: (1) The effect of the thermal contact resistance between the materials is to increase the maximum temperature of the system.

(2) Can you explain why the temperature distribution in the material B is not affected by the presence of the thermal contact resistance at the materials' interface?

PROBLEM 3.76

KNOWN: Plane wall of thickness $2L$, thermal conductivity k with uniform energy generation \dot{q} . For case 1, boundary at $x = -L$ is perfectly insulated, while boundary at $x = +L$ is maintained at $T_o = 50^\circ\text{C}$. For case 2, the boundary conditions are the same, but a thin dielectric strip with thermal resistance $R_t'' = 0.0005 \text{ m}^2 \cdot \text{K} / \text{W}$ is inserted at the mid-plane.

FIND: (a) Sketch the temperature distribution for case 1 on T - x coordinates and describe key features; identify and calculate the maximum temperature in the wall, (b) Sketch the temperature distribution for case 2 on the same T - x coordinates and describe the key features; (c) What is the temperature difference between the two walls at $x = 0$ for case 2? And (d) What is the location of the maximum temperature of the composite wall in case 2; calculate this temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in the plane and composite walls, and (3) Constant properties.

ANALYSIS: (a) For case 1, the temperature distribution, $T_1(x)$ vs. x , is parabolic as shown in the schematic below and the gradient is zero at the insulated boundary, $x = -L$. From Eq. 3.43 (see discussion after Eq. 3.44),

$$T_1(-L) - T_1(+L) = \frac{\dot{q}(2L)^2}{2k} = \frac{5 \times 10^6 \text{ W/m}^3 (2 \times 0.020 \text{ m})^2}{2 \times 50 \text{ W/m} \cdot \text{K}} = 80^\circ\text{C}$$

and since $T_1(+L) = T_o = 50^\circ\text{C}$, the maximum temperature occurs at $x = -L$,

$$T_1(-L) = T_1(+L) + 80^\circ\text{C} = 130^\circ\text{C}$$

(b) For case 2, the temperature distribution, $T_2(x)$ vs. x , is piece-wise parabolic, with zero gradient at $x = -L$ and a drop across the dielectric strip, ΔT_{AB} . The temperature gradients at either side of the dielectric strip are equal.

(c) For case 2, the temperature drop across the thin dielectric strip follows from the surface energy balance shown above.

$$q_x''(0) = \Delta T_{AB} / R_t'' \quad q_x''(0) = \dot{q}L$$

$$\Delta T_{AB} = R_t'' \dot{q}L = 0.0005 \text{ m}^2 \cdot \text{K} / \text{W} \times 5 \times 10^6 \text{ W/m}^3 \times 0.020 \text{ m} = 50^\circ\text{C}.$$

(d) For case 2, the maximum temperature in the composite wall occurs at $x = -L$, with the value,

$$T_2(-L) = T_1(-L) + \Delta T_{AB} = 130^\circ\text{C} + 50^\circ\text{C} = 180^\circ\text{C}$$

<

PROBLEM 3.77

KNOWN: Geometry and boundary conditions of a nuclear fuel element.

FIND: (a) Expression for the temperature distribution in the fuel, (b) Form of temperature distribution for the entire system.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Uniform generation, (4) Constant properties, (5) Negligible contact resistance between fuel and cladding.

ANALYSIS: (a) The general solution to the heat equation, Eq. 3.39,

$$\frac{d^2T}{dx^2} + \frac{\dot{q}}{k_f} = 0 \quad (-L \leq x \leq +L)$$

is
$$T = -\frac{\dot{q}}{2k_f}x^2 + C_1x + C_2.$$

The insulated wall at $x = -(L+b)$ dictates that the heat flux at $x = -L$ is zero (for an energy balance applied to a control volume about the wall, $\dot{E}_{in} = \dot{E}_{out} = 0$). Hence

$$\left. \frac{dT}{dx} \right|_{x=-L} = -\frac{\dot{q}}{k_f}(-L) + C_1 = 0 \quad \text{or} \quad C_1 = -\frac{\dot{q}L}{k_f}$$

$$T = -\frac{\dot{q}}{2k_f}x^2 - \frac{\dot{q}L}{k_f}x + C_2. \quad (1)$$

The value of $T_{s,1}$ may be determined from the energy conservation requirement that $\dot{E}_g = \dot{q}_{cond} = \dot{q}_{conv}$, or on a unit area basis.

$$\dot{q}(2L) = \frac{k_s}{b}(T_{s,1} - T_{s,2}) = h(T_{s,2} - T_\infty).$$

Hence,

$$T_{s,1} = \frac{\dot{q}(2Lb)}{k_s} + T_{s,2} \quad \text{where} \quad T_{s,2} = \frac{\dot{q}(2L)}{h} + T_\infty$$

$$T_{s,1} = \frac{\dot{q}(2Lb)}{k_s} + \frac{\dot{q}(2L)}{h} + T_\infty.$$

Continued

PROBLEM 3.77 (Cont.)

Hence from Eq. (1),

$$T(L) = T_{s,1} = \frac{\dot{q}(2Lb)}{k_s} + \frac{\dot{q}(2L)}{h} + T_\infty = -\frac{3}{2} \frac{\dot{q}(L^2)}{k_f} + C_2$$

which yields

$$C_2 = T_\infty + \dot{q}L \left[\frac{2b}{k_s} + \frac{2}{h} + \frac{3}{2} \frac{L}{k_f} \right]$$

Hence, the temperature distribution for $(-L \leq x \leq +L)$ is

$$T = -\frac{\dot{q}}{2k_f}x^2 - \frac{\dot{q}L}{k_f}x + \dot{q}L \left[\frac{2b}{k_s} + \frac{2}{h} + \frac{3}{2} \frac{L}{k_f} \right] + T_\infty$$

<

(b) For the temperature distribution shown below,

$$\begin{aligned} (-L-b) \leq x \leq -L: & \quad dT/dx=0, \quad T=T_{\max} \\ -L \leq x \leq +L: & \quad |dT/dx| \uparrow \text{ with } \uparrow x \\ +L \leq x \leq L+b: & \quad (dT/dx) \text{ is const.} \end{aligned}$$

PROBLEM 3.78

KNOWN: Thermal conductivity, heat generation and thickness of fuel element. Thickness and thermal conductivity of cladding. Surface convection conditions.

FIND: (a) Temperature distribution in fuel element with one surface insulated and the other cooled by convection. Largest and smallest temperatures and corresponding locations. (b) Same as part (a) but with equivalent convection conditions at both surfaces. (c) Plot of temperature distributions.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state, (3) Uniform generation, (4) Constant properties, (5) Negligible contact resistance.

ANALYSIS: (a) From Eq. C.1,

$$T(x) = \frac{\dot{q} L^2}{2k_f} \left(1 - \frac{x^2}{L^2} \right) + \frac{T_{s,2} - T_{s,1}}{2} \frac{x}{L} + \frac{T_{s,1} + T_{s,2}}{2} \quad (1)$$

With an insulated surface at $x = -L$, Eq. C.10 yields

$$T_{s,1} - T_{s,2} = \frac{2\dot{q} L^2}{k_f} \quad (2)$$

and with convection at $x = L + b$, Eq. C.13 yields

$$U(T_{s,2} - T_\infty) = \dot{q} L - \frac{k_f}{2L} (T_{s,2} - T_{s,1})$$

$$T_{s,1} - T_{s,2} = \frac{2LU}{k_f} (T_{s,2} - T_\infty) - \frac{2\dot{q} L^2}{k_f} \quad (3)$$

where $U^{-1} = h^{-1} + b/k_g$. Subtracting Eq. (2) from Eq. (3),

$$0 = \frac{2LU}{k_f} (T_{s,2} - T_\infty) - \frac{4\dot{q} L^2}{k_f}$$

$$T_{s,2} = T_\infty + \frac{2\dot{q} L}{U} \quad (4)$$

Continued

PROBLEM 3.78 (Cont.)

Alternatively, this result could have been found from an energy balance on the wall which equates the generated heat to the heat leaving at $L+b$,

$$2\dot{q}L = U(T_{s,2} - T_{\infty})$$

Substituting Eq. (4) into Eq. (2)

$$T_{s,1} = T_{\infty} + 2\dot{q}L \left(\frac{L}{k_f} + \frac{1}{U} \right) \quad (5)$$

Substituting Eqs. (4) and (5) into Eq. (1),

$$T(x) = -\frac{\dot{q}}{2k_f}x^2 - \frac{\dot{q}L}{k_f}x + \dot{q}L \left(\frac{2}{U} + \frac{3}{2} \frac{L}{k_f} \right) + T_{\infty}$$

Or,

$$T(x) = -\frac{\dot{q}}{2k_f}x^2 - \frac{\dot{q}L}{k_f}x + \dot{q}L \left(\frac{2b}{k_s} + \frac{2}{h} + \frac{3}{2} \frac{L}{k_f} \right) + T_{\infty} \quad (6) <$$

The maximum temperature occurs at $x = -L$ and is

$$T(-L) = 2\dot{q}L \left(\frac{b}{k_s} + \frac{1}{h} + \frac{L}{k_f} \right) + T_{\infty}$$

$$T(-L) = 2 \times 2 \times 10^7 \text{ W/m}^3 \times 0.015 \text{ m} \left(\frac{0.003 \text{ m}}{15 \text{ W/m} \cdot \text{K}} + \frac{1}{10,000 \text{ W/m}^2 \cdot \text{K}} + \frac{0.015 \text{ m}}{60 \text{ W/m} \cdot \text{K}} \right) + 200^\circ\text{C} = 530^\circ\text{C} <$$

The lowest temperature is at $x = +L$ and is

$$T(+L) = -\frac{3}{2} \frac{\dot{q}L^2}{k_f} + \dot{q}L \left(\frac{2b}{k_s} + \frac{2}{h} + \frac{3}{2} \frac{L}{k_f} \right) + T_{\infty} = 380^\circ\text{C} <$$

(b) If a convection condition is maintained at $x = -L$, Eq. C.12 reduces to

$$U(T_{\infty} - T_{s,1}) = -\dot{q}L - \frac{k_f}{2L}(T_{s,2} - T_{s,1})$$

$$T_{s,1} - T_{s,2} = \frac{2LU}{k_f}(T_{s,1} - T_{\infty}) - \frac{2\dot{q}L^2}{k_f} \quad (7)$$

Subtracting Eq. (7) from Eq. (3),

$$0 = \frac{2LU}{k_f}(T_{s,2} - T_{\infty} - T_{s,1} + T_{\infty}) \quad \text{or} \quad T_{s,1} = T_{s,2}$$

Hence, from Eq. (7)

Continued

PROBLEM 3.78 (Cont.)

$$T_{s,1} = T_{s,2} = \frac{\dot{q}L}{U} + T_{\infty} = \dot{q}L \left(\frac{1}{h} + \frac{b}{k_s} \right) + T_{\infty} \quad (8)$$

Substituting into Eq. (1), the temperature distribution is

$$T(x) = \frac{\dot{q}L^2}{2k_f} \left(1 - \frac{x^2}{L^2} \right) + \dot{q}L \left(\frac{1}{h} + \frac{b}{k_s} \right) + T_{\infty} \quad (9)$$

The maximum temperature is at $x = 0$ and is

$$T(0) = \frac{2 \times 10^7 \text{ W/m}^3 (0.015 \text{ m})^2}{2 \times 60 \text{ W/m} \cdot \text{K}} + 2 \times 10^7 \text{ W/m}^3 \times 0.015 \text{ m} \left(\frac{1}{10,000 \text{ W/m}^2 \cdot \text{K}} + \frac{0.003 \text{ m}}{15 \text{ W/m} \cdot \text{K}} \right) + 200^\circ\text{C}$$

$$T(0) = 37.5^\circ\text{C} + 90^\circ\text{C} + 200^\circ\text{C} = 327.5^\circ\text{C}$$

The minimum temperature at $x = \pm L$ is

$$T_{s,1} = T_{s,2} = 2 \times 10^7 \text{ W/m}^3 (0.015 \text{ m}) \left(\frac{1}{10,000 \text{ W/m}^2 \cdot \text{K}} + \frac{0.003 \text{ m}}{15 \text{ W/m} \cdot \text{K}} \right) + 200^\circ\text{C} = 290^\circ\text{C}$$

(c) The temperature distributions are as shown.

The amount of heat generation is the same for both cases, but the ability to transfer heat from both surfaces for case (b) results in lower temperatures throughout the fuel element.

COMMENTS: Note that for case (a), the temperature in the insulated cladding is constant and equivalent to $T_{s,1} = 530^\circ\text{C}$.

PROBLEM 3.79

KNOWN: Wall of thermal conductivity k and thickness L with uniform generation \dot{q} ; strip heater with uniform heat flux q_o'' ; prescribed inside and outside air conditions (h_i , $T_{\infty,i}$, h_o , $T_{\infty,o}$).

FIND: (a) Sketch temperature distribution in wall if none of the heat generated within the wall is lost to the outside air, (b) Temperatures at the wall boundaries $T(0)$ and $T(L)$ for the prescribed condition, (c) Value of q_o'' required to maintain this condition, (d) Temperature of the outer surface, $T(L)$, if $\dot{q}=0$ but q_o'' corresponds to the value calculated in (c).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Uniform volumetric generation, (4) Constant properties.

ANALYSIS: (a) If none of the heat generated within the wall is lost to the outside of the chamber, the gradient at $x = 0$ must be zero. Since \dot{q} is uniform, the temperature distribution is parabolic, with $T(L)$

$> T_{\infty,i}$.

(b) To find temperatures at the boundaries of wall, begin with the general solution to the appropriate form of the heat equation (Eq.3.40).

$$T(x) = -\frac{\dot{q}}{2k}x^2 + C_1x + C_2 \quad (1)$$

From the first boundary condition,

$$\left. \frac{dT}{dx} \right|_{x=0} = 0 \rightarrow C_1 = 0. \quad (2)$$

Two approaches are possible using different forms for the second boundary condition.

Approach No. 1: With boundary condition $\rightarrow T(0) = T_1$

$$T(x) = -\frac{\dot{q}}{2k}x^2 + T_1 \quad (3)$$

To find T_1 , perform an overall energy balance on the wall

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0$$

$$-h[T(L) - T_{\infty,i}] + \dot{q}L = 0 \quad T(L) = T_2 = T_{\infty,i} + \frac{\dot{q}L}{h} \quad (4)$$

Continued

PROBLEM 3.79 (Cont.)

and from Eq. (3) with $x = L$ and $T(L) = T_2$,

$$T(L) = -\frac{\dot{q}}{2k}L^2 + T_1 \quad \text{or} \quad T_1 = T_2 + \frac{\dot{q}}{2k}L^2 = T_{\infty,i} + \frac{\dot{q}L}{h} + \frac{\dot{q}L^2}{2k} \quad (5,6)$$

Substituting numerical values into Eqs. (4) and (6), find

$$T_2 = 50^\circ\text{C} + 1000 \text{ W/m}^3 \times 0.200 \text{ m} / 20 \text{ W/m}^2 \cdot \text{K} = 50^\circ\text{C} + 10^\circ\text{C} = 60^\circ\text{C} \quad <$$

$$T_1 = 60^\circ\text{C} + 1000 \text{ W/m}^3 \times (0.200 \text{ m})^2 / 2 \times 4 \text{ W/m} \cdot \text{K} = 65^\circ\text{C}. \quad <$$

Approach No. 2: Using the boundary condition

$$-k \frac{dT}{dx} \Big|_{x=L} = h [T(L) - T_{\infty,i}]$$

yields the following temperature distribution which can be evaluated at $x = 0, L$ for the required temperatures,

$$T(x) = -\frac{\dot{q}}{2k}(x^2 - L^2) + \frac{\dot{q}L}{h} + T_{\infty,i}.$$

(c) The value of q_o'' when $T(0) = T_1 = 65^\circ\text{C}$ follows from the circuit

$$q_o'' = \frac{T_1 - T_{\infty,o}}{1/h_o}$$

$$q_o'' = 5 \text{ W/m}^2 \cdot \text{K} (65 - 25)^\circ\text{C} = 200 \text{ W/m}^2. \quad <$$

(d) With $\dot{q}=0$, the situation is represented by the thermal circuit shown. Hence,

$$q_o'' = q_a'' + q_b''$$

$$q_o'' = \frac{T_1 - T_{\infty,o}}{1/h_o} + \frac{T_1 - T_{\infty,i}}{L/k + 1/h_i}$$

which yields

$$T_1 = 55^\circ\text{C}. \quad <$$

PROBLEM 3.80

KNOWN: Wall of thermal conductivity k and thickness L with uniform generation and strip heater with uniform heat flux q_o'' ; prescribed inside and outside air conditions ($T_{\infty,i}$, h_i , $T_{\infty,o}$, h_o). Strip heater acts to guard against heat losses from the wall to the outside.

FIND: Compute and plot q_o'' and $T(0)$ as a function of \dot{q} for $200 \leq \dot{q} \leq 2000 \text{ W/m}^3$ and $T_{\infty,i} = 30, 50$ and 70°C .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Uniform volumetric generation, (4) Constant properties.

ANALYSIS: If no heat generated within the wall will be lost to the outside of the chamber, the gradient at the position $x = 0$ must be zero. Since \dot{q} is uniform, the temperature distribution must be parabolic as shown in the sketch.

To determine the required heater flux q_o'' as a function of the operation conditions \dot{q} and $T_{\infty,i}$, the analysis begins by considering the temperature distribution in the wall and then surface energy balances at the two wall surfaces. The analysis is organized for easy treatment with equation-solving software.

Temperature distribution in the wall, $T(x)$: The general solution for the temperature distribution in the wall is, Eq. 3.40,

$$T(x) = -\frac{\dot{q}}{2k}x^2 + C_1x + C_2$$

and the guard condition at the outer wall, $x = 0$, requires that the conduction heat flux be zero. Using Fourier's law,

$$q_x''(0) = -k \left. \frac{dT}{dx} \right|_{x=0} = -kC_1 = 0 \quad (C_1 = 0) \quad (1)$$

At the outer wall, $x = 0$,

$$T(0) = C_2 \quad (2)$$

Heater energy balance, $x = 0$:

$$\dot{E}_{\text{in}} + \dot{E}_g - \dot{E}_{\text{out}} = 0$$

$$0 + q_o'' - q_{\text{cv},o}'' - q_x''(0) = 0 \quad (3)$$

$$q_{\text{cv},o}'' = h_o (T(0) - T_{\infty,o}), q_x''(0) = 0 \quad (4a,b)$$

Continued...

PROBLEM 3.80 (Cont.)

Surface energy balance, $x = L$:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$q_x''(L) - q_{\text{cv},i}'' = 0 \quad (5)$$

$$q_x''(L) = -k \left. \frac{dT}{dx} \right|_{x=L} = +\dot{q}L \quad (6)$$

$$q_{\text{cv},i}'' = h_i [T(L) - T_{\infty,i}]$$

$$q_{\text{cv},i}'' = h_i \left[-\frac{\dot{q}}{2k} L^2 + T(0) - T_{\infty,i} \right] \quad (7)$$

Solving Eqs. (3) through (7) simultaneously with appropriate numerical values and performing the parametric analysis, the results are plotted below.

From the first plot, the heater flux q_o'' is a linear function of the volumetric generation rate \dot{q} . As expected, the higher \dot{q} and $T_{\infty,i}$, the higher the heat flux required to maintain the guard condition ($q_x''(0) = 0$). Notice that for any \dot{q} condition, equal changes in $T_{\infty,i}$ result in equal changes in the required q_o'' . The outer wall temperature $T(0)$ is also linearly dependent upon \dot{q} . From our knowledge of the temperature distribution, it follows that for any \dot{q} condition, the outer wall temperature $T(0)$ will track changes in $T_{\infty,i}$.

PROBLEM 3.81

KNOWN: Plane wall with prescribed nonuniform volumetric generation having one boundary insulated and the other isothermal.

FIND: Temperature distribution, $T(x)$, in terms of x , L , k , \dot{q}_0 and T_0 .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x -direction, (3) Constant properties.

ANALYSIS: The appropriate form the heat diffusion equation is

$$\frac{d}{dx} \left[\frac{dT}{dx} \right] + \frac{\dot{q}}{k} = 0.$$

Noting that $\dot{q} = \dot{q}(x) = \dot{q}_0 (1 - x/L)$, substitute for $\dot{q}(x)$ into the above equation, separate variables and then integrate,

$$d \left[\frac{dT}{dx} \right] = -\frac{\dot{q}_0}{k} \left[1 - \frac{x}{L} \right] dx \quad \frac{dT}{dx} = -\frac{\dot{q}_0}{k} \left[x - \frac{x^2}{2L} \right] + C_1.$$

Separate variables and integrate again to obtain the general form of the temperature distribution in the wall,

$$dT = -\frac{\dot{q}_0}{k} \left[x - \frac{x^2}{2L} \right] dx + C_1 dx \quad T(x) = -\frac{\dot{q}_0}{k} \left[\frac{x^2}{2} - \frac{x^3}{6L} \right] + C_1 x + C_2.$$

Identify the boundary conditions at $x = 0$ and $x = L$ to evaluate C_1 and C_2 . At $x = 0$,

$$T(0) = T_0 = -\frac{\dot{q}_0}{k}(0 - 0) + C_1 \cdot 0 + C_2 \quad \text{hence, } C_2 = T_0$$

At $x = L$,

$$\left. \frac{dT}{dx} \right|_{x=L} = 0 = -\frac{\dot{q}_0}{k} \left[L - \frac{L^2}{2L} \right] + C_1 \quad \text{hence, } C_1 = \frac{\dot{q}_0 L}{2k}$$

The temperature distribution is

$$T(x) = -\frac{\dot{q}_0}{k} \left[\frac{x^2}{2} - \frac{x^3}{6L} \right] + \frac{\dot{q}_0 L}{2k} x + T_0. \quad <$$

COMMENTS: It is good practice to test the final result for satisfying BCs. The heat flux at $x = 0$ can be found using Fourier's law or from an overall energy balance

$$\dot{E}_{\text{out}} = \dot{E}_{\dot{q}} = \int_0^L \dot{q} dV \quad \text{to obtain} \quad \dot{q}_{\text{out}} = \dot{q}_0 L/2.$$

PROBLEM 3.82

KNOWN: Distribution of volumetric heating and surface conditions associated with a quartz window.

FIND: Temperature distribution in the quartz.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible radiation emission and convection at inner surface ($x = 0$) and negligible emission from outer surface, (4) Constant properties.

ANALYSIS: The appropriate form of the heat equation for the quartz is obtained by substituting the prescribed form of \dot{q} into Eq. 3.39.

$$\frac{d^2 T}{dx^2} + \frac{\alpha(1-\beta)q_o''}{k} e^{-\alpha x} = 0$$

Integrating,

$$\frac{dT}{dx} = + \frac{(1-\beta)q_o''}{k} e^{-\alpha x} + C_1 \quad T = - \frac{(1-\beta)}{k\alpha} q_o'' e^{-\alpha x} + C_1 x + C_2$$

Boundary Conditions:

$$\begin{aligned} -k \frac{dT}{dx} \Big|_{x=0} &= \beta q_o'' \\ -k \frac{dT}{dx} \Big|_{x=L} &= h [T(L) - T_\infty] \end{aligned}$$

Hence, at $x = 0$:

$$\begin{aligned} -k \left[\frac{(1-\beta)}{k} q_o'' + C_1 \right] &= \beta q_o'' \\ C_1 &= -q_o'' / k \end{aligned}$$

At $x = L$:

$$-k \left[\frac{(1-\beta)}{k} q_o'' e^{-\alpha L} + C_1 \right] = h \left[- \frac{(1-\beta)}{k\alpha} q_o'' e^{-\alpha L} + C_1 L + C_2 - T_\infty \right]$$

Substituting for C_1 and solving for C_2 ,

$$C_2 = \frac{q_o''}{h} \left[1 - (1-\beta) e^{-\alpha L} \right] + \frac{q_o'' L}{k} + \frac{q_o'' (1-\beta)}{k\alpha} e^{-\alpha L} + T_\infty.$$

Hence,

$$T(x) = \frac{(1-\beta)q_o''}{k\alpha} \left[e^{-\alpha L} - e^{-\alpha x} \right] + \frac{q_o''}{k} (L - x) + \frac{q_o''}{h} \left[1 - (1-\beta) e^{-\alpha L} \right] + T_\infty. <$$

COMMENTS: The temperature distribution depends strongly on the radiative coefficients, α and β . For $\alpha \rightarrow \infty$ or $\beta = 1$, the heating occurs entirely at $x = 0$ (no volumetric heating).

PROBLEM 3.83

KNOWN: Radial distribution of heat dissipation in a cylindrical container of radioactive wastes. Surface convection conditions.

FIND: Radial temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across container wall.

ANALYSIS: The appropriate form of the heat equation is

$$\frac{1}{r} \frac{d}{dr} \left(r \frac{dT}{dr} \right) = -\frac{\dot{q}}{k} = -\frac{\dot{q}_0}{k} \left(1 - \frac{r^2}{r_0^2} \right)$$

$$r \frac{dT}{dr} = -\frac{\dot{q}_0 r^2}{2k} + \frac{\dot{q}_0 r^4}{4kr_0^2} + C_1 \quad T = -\frac{\dot{q}_0 r^2}{4k} + \frac{\dot{q}_0 r^4}{16kr_0^2} + C_1 \ln r + C_2.$$

From the boundary conditions,

$$\left. \frac{dT}{dr} \right|_{r=0} = 0 \rightarrow C_1 = 0 \quad -k \left. \frac{dT}{dr} \right|_{r=r_0} = h [T(r_0) - T_\infty]$$

$$+\frac{\dot{q}_0 r_0}{2} - \frac{\dot{q}_0 r_0}{4} = h \left[-\frac{\dot{q}_0 r_0^2}{4k} + \frac{\dot{q}_0 r_0^2}{16k} + C_2 - T_\infty \right]$$

$$C_2 = \frac{\dot{q}_0 r_0}{4h} + \frac{3\dot{q}_0 r_0^2}{16k} + T_\infty.$$

Hence

$$T(r) = T_\infty + \frac{\dot{q}_0 r_0}{4h} + \frac{\dot{q}_0 r_0^2}{k} \left[\frac{3}{16} - \frac{1}{4} \left(\frac{r}{r_0} \right)^2 + \frac{1}{16} \left(\frac{r}{r_0} \right)^4 \right]. \quad <$$

COMMENTS: Applying the above result at r_0 yields

$$T_s = T(r_0) = T_\infty + (\dot{q}_0 r_0) / 4h$$

The same result may be obtained by applying an energy balance to a control surface about the container, where $\dot{E}_g = q_{conv}$. The maximum temperature exists at $r = 0$.

PROBLEM 3.84

KNOWN: Cylindrical shell with uniform volumetric generation is insulated at inner surface and exposed to convection on the outer surface.

FIND: (a) Temperature distribution in the shell in terms of r_i , r_o , \dot{q} , h , T_∞ and k , (b) Expression for the heat rate per unit length at the outer radius, $q'(r_o)$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial (cylindrical) conduction in shell, (3) Uniform generation, (4) Constant properties.

ANALYSIS: (a) The general form of the temperature distribution and boundary conditions are

$$T(r) = -\frac{\dot{q}}{4k}r^2 + C_1 \ln r + C_2$$

$$\text{at } r = r_i: \quad \left. \frac{dT}{dr} \right|_{r_i} = 0 = -\frac{\dot{q}}{2k}r_i + C_1 \frac{1}{r_i} + 0 \quad C_1 = \frac{\dot{q}}{2k}r_i^2$$

$$\text{at } r = r_o: \quad -k \left. \frac{dT}{dr} \right|_{r_o} = h [T(r_o) - T_\infty] \quad \text{surface energy balance}$$

$$-k \left[-\frac{\dot{q}}{2k}r_o + \left(\frac{\dot{q}}{2k}r_i^2 \cdot \frac{1}{r_o} \right) \right] = h \left[-\frac{\dot{q}}{4k}r_o^2 + \left(\frac{\dot{q}}{2k}r_i^2 \right) \ln r_o + C_2 - T_\infty \right]$$

$$C_2 = -\frac{\dot{q}r_o}{2h} \left[1 - \left(\frac{r_i}{r_o} \right)^2 \right] + \frac{\dot{q}r_o^2}{2k} \left[\frac{1}{2} - \left(\frac{r_i}{r_o} \right)^2 \ln r_o \right] + T_\infty$$

Hence,

$$T(r) = \frac{\dot{q}}{4k} (r_o^2 - r^2) + \frac{\dot{q}r_i^2}{2k} \ln \left(\frac{r}{r_o} \right) - \frac{\dot{q}r_o}{2h} \left[1 - \left(\frac{r_i}{r_o} \right)^2 \right] + T_\infty. \quad <$$

(b) From an overall energy balance on the shell,

$$q'_r(r_o) = \dot{E}_g = \dot{q}\pi(r_o^2 - r_i^2). \quad <$$

Alternatively, the heat rate may be found using Fourier's law and the temperature distribution,

$$q'_r(r) = -k(2\pi r_o) \left. \frac{dT}{dr} \right|_{r_o} = -2\pi k r_o \left[-\frac{\dot{q}}{2k}r_o + \frac{\dot{q}r_i^2}{2k} \frac{1}{r_o} + 0 + 0 \right] = \dot{q}\pi(r_o^2 - r_i^2)$$

PROBLEM 3.85

KNOWN: The solid tube of Example 3.8 with inner and outer radii, 50 and 100 mm, and a thermal conductivity of 5 W/m·K. The inner surface is cooled by a fluid at 30°C with a convection coefficient of 1000 W/m²·K.

FIND: Calculate and plot the temperature distributions for volumetric generation rates of 1×10^5 , 5×10^5 , and 1×10^6 W/m³. Use Eq. (7) with Eq. (10) of the Example 3.8 in the *IHT Workspace*.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties and (4) Uniform volumetric generation.

ANALYSIS: From Example 3.8, the temperature distribution in the tube is given by Eq. (7),

$$T(r) = T_{s,2} + \frac{\dot{q}}{4k} (r_2^2 - r^2) - \frac{\dot{q}}{2k} r_2^2 \ln\left(\frac{r_2}{r}\right) \quad r_1 \leq r \leq r_2 \quad (1)$$

The temperature at the inner boundary, $T_{s,1}$, follows from the surface energy balance, Eq. (10),

$$\pi \dot{q} (r_2^2 - r_1^2) = h 2\pi r_1 (T_{s,1} - T_\infty) \quad (2)$$

For the conditions prescribed in the schematic with $\dot{q} = 1 \times 10^5$ W/m³, Eqs. (1) and (2), with $r = r_1$ and $T(r) = T_{s,1}$, are solved simultaneously to find $T_{s,2} = 69.3^\circ\text{C}$. Eq. (1), with $T_{s,2}$ now a known parameter, can be used to determine the temperature distribution, $T(r)$. The results for different values of the generation rate are shown in the graph.

COMMENTS: (1) The temperature distributions are parabolic with a zero gradient at the insulated outer boundary, $r = r_2$. The effect of increasing \dot{q} is to increase the maximum temperature in the tube, which always occurs at the outer boundary.

(2) The equations used to generate the graphical result in the *IHT Workspace* are shown below.

```
// The temperature distribution, from Eq. 7, Example 3.8
T_r = Ts2 + qdot/(4*k) * (r2^2 - r^2) - qdot / (2*k) * r2^2 * ln (r2/r)
// The temperature at the inner surface, from Eq. 7
Ts1 = Ts2 + qdot / (4*k) * (r2^2 - r1^2) - qdot / (2*k) * r2^2 * ln (r2/r1)
// The energy balance on the surface, from Eq. 10
pi * qdot * (r2^2 - r1^2) = h * 2 * pi * r1 * (Ts1 - Tinf)
```

PROBLEM 3.86

KNOWN: Diameter, resistivity, thermal conductivity, emissivity, voltage, and maximum temperature of heater wire. Convection coefficient and air exit temperature. Temperature of surroundings.

FIND: Maximum operating current, heater length and power rating.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Uniform wire temperature, (3) Constant properties, (4) Radiation exchange with large surroundings.

ANALYSIS: Assuming a uniform wire temperature, $T_{\max} = T(r=0) \equiv T_o \approx T_s$, the maximum volumetric heat generation may be obtained from Eq. (3.55), but with the total heat transfer coefficient, $h_t = h + h_r$, used in lieu of the convection coefficient h . With

$$h_r = \epsilon \sigma (T_s + T_{\text{sur}}) (T_s^2 + T_{\text{sur}}^2) = 0.20 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1473 + 323) \text{ K} (1473^2 + 323^2) \text{ K}^2 = 46.3 \text{ W/m}^2 \cdot \text{K}$$

$$h_t = (250 + 46.3) \text{ W/m}^2 \cdot \text{K} = 296.3 \text{ W/m}^2 \cdot \text{K}$$

$$\dot{q}_{\max} = \frac{2h_t}{r_o} (T_s - T_\infty) = \frac{2(296.3 \text{ W/m}^2 \cdot \text{K})}{0.0005 \text{ m}} (1150^\circ\text{C}) = 1.36 \times 10^9 \text{ W/m}^3$$

Hence, with $\dot{q} = \frac{I^2 R_e}{\forall} = \frac{I^2 (\rho_e L / A_c)}{L A_c} = \frac{I^2 \rho_e}{A_c^2} = \frac{I^2 \rho_e}{(\pi D^2 / 4)^2}$

$$I_{\max} = \left(\frac{\dot{q}_{\max}}{\rho_e} \right)^{1/2} \frac{\pi D^2}{4} = \left(\frac{1.36 \times 10^9 \text{ W/m}^3}{10^{-6} \Omega \cdot \text{m}} \right)^{1/2} \frac{\pi (0.001 \text{ m})^2}{4} = 29.0 \text{ A} <$$

Also, with $\Delta E = I R_e = I (\rho_e L / A_c)$,

$$L = \frac{\Delta E \cdot A_c}{I_{\max} \rho_e} = \frac{110 \text{ V} \left[\pi (0.001 \text{ m})^2 / 4 \right]}{29.0 \text{ A} (10^{-6} \Omega \cdot \text{m})} = 2.98 \text{ m} <$$

and the power rating is

$$P_{\text{elec}} = \Delta E \cdot I_{\max} = 110 \text{ V} (29 \text{ A}) = 3190 \text{ W} = 3.19 \text{ kW} <$$

COMMENTS: To assess the validity of assuming a uniform wire temperature, Eq. (3.53) may be used to compute the centerline temperature corresponding to \dot{q}_{\max} and a surface temperature of

$$1200^\circ\text{C}. \text{ It follows that } T_o = \frac{\dot{q} r_o^2}{4k} + T_s = \frac{1.36 \times 10^9 \text{ W/m}^3 (0.0005 \text{ m})^2}{4(25 \text{ W/m} \cdot \text{K})} + 1200^\circ\text{C} = 1203^\circ\text{C}. \text{ With only a}$$

3°C temperature difference between the centerline and surface of the wire, the assumption is *excellent*.

PROBLEM 3.87

KNOWN: Energy generation in an aluminum-clad, thorium fuel rod under specified operating conditions.

FIND: (a) Whether prescribed operating conditions are acceptable, (b) Effect of \dot{q} and h on acceptable operating conditions.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in r -direction, (2) Steady-state conditions, (3) Constant properties, (4) Negligible temperature gradients in aluminum and contact resistance between aluminum and thorium.

PROPERTIES: Table A-1, Aluminum, pure: M.P. = 933 K; Table A-1, Thorium: M.P. = 2023 K, $k \approx 60$ W/m·K.

ANALYSIS: (a) System failure would occur if the melting point of either the thorium or the aluminum were exceeded. From Eq. 3.53, the maximum thorium temperature, which exists at $r = 0$, is

$$T(0) = \frac{\dot{q}r_o^2}{4k} + T_s = T_{Th,max}$$

where, from the energy balance equation, Eq. 3.55, the surface temperature, which is also the aluminum temperature, is

$$T_s = T_\infty + \frac{\dot{q}r_o}{2h} = T_{Al}$$

Hence,

$$T_{Al} = T_s = 95^\circ\text{C} + \frac{7 \times 10^8 \text{ W/m}^3 \times 0.0125 \text{ m}}{14,000 \text{ W/m}^2 \cdot \text{K}} = 720^\circ\text{C} = 993 \text{ K}$$

$$T_{Th,max} = \frac{7 \times 10^8 \text{ W/m}^3 (0.0125 \text{ m})^2}{4 \times 60 \text{ W/m} \cdot \text{K}} + 993 \text{ K} = 1449 \text{ K}$$

Although $T_{Th,max} < \text{M.P.}_{Th}$ and the thorium would not melt, $T_{Al} > \text{M.P.}_{Al}$ and the cladding would melt under the proposed operating conditions. The problem could be eliminated by *decreasing* \dot{q} or r_o , *increasing* h or using a cladding material with a higher melting point.

(b) Using the one-dimensional, steady-state conduction model (solid cylinder) of the IHT software, the following radial temperature distributions were obtained for parametric variations in \dot{q} and h .

Continued...

PROBLEM 3.87 (Cont.)

For $h = 10,000 \text{ W/m}^2\cdot\text{K}$, which represents a reasonable upper limit with water cooling, the temperature of the aluminum would be well below its melting point for $\dot{q} = 7 \times 10^8 \text{ W/m}^3$, but would be close to the melting point for $\dot{q} = 8 \times 10^8 \text{ W/m}^3$ and would exceed it for $\dot{q} = 9 \times 10^8 \text{ W/m}^3$. Hence, under the best of conditions, $\dot{q} \approx 7 \times 10^8 \text{ W/m}^3$ corresponds to the maximum allowable energy generation. However, if coolant flow conditions are constrained to provide values of $h < 10,000 \text{ W/m}^2\cdot\text{K}$, volumetric heating would have to be reduced. Even for \dot{q} as low as $2 \times 10^8 \text{ W/m}^3$, operation could not be sustained for $h = 2000 \text{ W/m}^2\cdot\text{K}$.

The effects of \dot{q} and h on the centerline and surface temperatures are shown below.

For $h = 2000$ and $5000 \text{ W/m}^2\cdot\text{K}$, the melting point of thorium would be approached for $\dot{q} \approx 4.4 \times 10^8$ and $8.5 \times 10^8 \text{ W/m}^3$, respectively. For $h = 2000$, 5000 and $10,000 \text{ W/m}^2\cdot\text{K}$, the melting point of aluminum would be approached for $\dot{q} \approx 1.6 \times 10^8$, 4.3×10^8 and $8.7 \times 10^8 \text{ W/m}^3$. Hence, the envelope of acceptable operating conditions must call for a reduction in \dot{q} with decreasing h , from a maximum of $\dot{q} \approx 7 \times 10^8 \text{ W/m}^3$ for $h = 10,000 \text{ W/m}^2\cdot\text{K}$.

COMMENTS: Note the problem which would arise in the event of a *loss of coolant*, for which case h would *decrease* drastically.

PROBLEM 3.88

KNOWN: Radii and thermal conductivities of reactor fuel element and cladding. Fuel heat generation rate. Temperature and convection coefficient of coolant.

FIND: (a) Expressions for temperature distributions in fuel and cladding, (b) Maximum fuel element temperature for prescribed conditions, (c) Effect of h on temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible contact resistance, (4) Constant properties.

ANALYSIS: (a) From Eqs. 3.49 and 3.23, the heat equations for the fuel (f) and cladding (c) are

$$\frac{1}{r} \frac{d}{dr} \left(r \frac{dT_f}{dr} \right) = -\frac{\dot{q}}{k_f} \quad (0 \leq r \leq r_1) \quad \frac{1}{r} \frac{d}{dr} \left(r \frac{dT_c}{dr} \right) = 0 \quad (r_1 \leq r \leq r_2)$$

Hence, integrating both equations twice,

$$\frac{dT_f}{dr} = -\frac{\dot{q}r}{2k_f} + \frac{C_1}{k_f r} \quad T_f = -\frac{\dot{q}r^2}{4k_f} + \frac{C_1}{k_f} \ln r + C_2 \quad (1,2)$$

$$\frac{dT_c}{dr} = \frac{C_3}{k_c r} \quad T_c = \frac{C_3}{k_c} \ln r + C_4 \quad (3,4)$$

The corresponding boundary conditions are:

$$\left. \frac{dT_f}{dr} \right|_{r=0} = 0 \quad T_f(r_1) = T_c(r_1) \quad (5,6)$$

$$\left. -k_f \frac{dT_f}{dr} \right|_{r=r_1} = \left. -k_c \frac{dT_c}{dr} \right|_{r=r_1} \quad \left. -k_c \frac{dT_c}{dr} \right|_{r=r_2} = h [T_c(r_2) - T_\infty] \quad (7,8)$$

Note that Eqs. (7) and (8) are obtained from surface energy balances at r_1 and r_2 , respectively. Applying Eq. (5) to Eq. (1), it follows that $C_1 = 0$. Hence,

$$T_f = -\frac{\dot{q}r^2}{4k_f} + C_2 \quad (9)$$

From Eq. (6), it follows that

$$-\frac{\dot{q}r_1^2}{4k_f} + C_2 = \frac{C_3 \ln r_1}{k_c} + C_4 \quad (10)$$

Continued...

PROBLEM 3.88 (Cont.)

Also, from Eq. (7),

$$\frac{\dot{q}r_1}{2} = -\frac{C_3}{r_1} \quad \text{or} \quad C_3 = -\frac{\dot{q}r_1^2}{2} \quad (11)$$

Finally, from Eq. (8), $-\frac{C_3}{r_2} = h \left[\frac{C_3}{k_c} \ln r_2 + C_4 - T_\infty \right]$ or, substituting for C_3 and solving for C_4

$$C_4 = \frac{\dot{q}r_1^2}{2r_2h} + \frac{\dot{q}r_1^2}{2k_c} \ln r_2 + T_\infty \quad (12)$$

Substituting Eqs. (11) and (12) into (10), it follows that

$$C_2 = \frac{\dot{q}r_1^2}{4k_f} - \frac{\dot{q}r_1^2 \ln r_1}{2k_c} + \frac{\dot{q}r_1^2}{2r_2h} + \frac{\dot{q}r_1^2}{2k_c} \ln r_2 + T_\infty$$

$$C_2 = \frac{\dot{q}r_1^2}{4k_f} + \frac{\dot{q}r_1^2}{2k_c} \ln \frac{r_2}{r_1} + \frac{\dot{q}r_1^2}{2r_2h} + T_\infty \quad (13)$$

Substituting Eq. (13) into (9),

$$T_f = \frac{\dot{q}}{4k_f} (r_1^2 - r^2) + \frac{\dot{q}r_1^2}{2k_c} \ln \frac{r_2}{r_1} + \frac{\dot{q}r_1^2}{2r_2h} + T_\infty \quad (14)$$

Substituting Eqs. (11) and (12) into (4),

$$T_c = \frac{\dot{q}r_1^2}{2k_c} \ln \frac{r_2}{r} + \frac{\dot{q}r_1^2}{2r_2h} + T_\infty \quad (15)$$

(b) Applying Eq. (14) at $r = 0$, the maximum fuel temperature for $h = 2000 \text{ W/m}^2 \cdot \text{K}$ is

$$T_f(0) = \frac{2 \times 10^8 \text{ W/m}^3 \times (0.006 \text{ m})^2}{4 \times 2 \text{ W/m} \cdot \text{K}} + \frac{2 \times 10^8 \text{ W/m}^3 \times (0.006 \text{ m})^2}{2 \times 25 \text{ W/m} \cdot \text{K}} \ln \frac{0.009 \text{ m}}{0.006 \text{ m}}$$

$$+ \frac{2 \times 10^8 \text{ W/m}^3 (0.006 \text{ m})^2}{2 \times (0.009 \text{ m}) 2000 \text{ W/m}^2 \cdot \text{K}} + 300 \text{ K}$$

$$T_f(0) = (900 + 58.4 + 200 + 300) \text{ K} = 1458 \text{ K} \quad (16)$$

(c) Temperature distributions for the prescribed values of h are as follows:

Continued...

PROBLEM 3.88 (Cont.)

Clearly, the ability to control the maximum fuel temperature by increasing h is limited, and even for $h \rightarrow \infty$, $T_f(0)$ exceeds 1000 K. The overall temperature drop, $T_f(0) - T_\infty$, is influenced principally by the low thermal conductivity of the fuel material.

COMMENTS: For the prescribed conditions, Eq. (14) yields, $T_f(0) - T_f(r_1) = \dot{q}r_1^2/4k_f = (2 \times 10^8 \text{ W/m}^3)(0.006 \text{ m})^2/8 \text{ W/m}\cdot\text{K} = 900 \text{ K}$, in which case, with no cladding and $h \rightarrow \infty$, $T_f(0) = 1200 \text{ K}$. To reduce $T_f(0)$ below 1000 K for the prescribed material, it is necessary to reduce \dot{q} .

PROBLEM 3.89

KNOWN: Dimensions and properties of tubular heater and external insulation. Internal and external convection conditions. Maximum allowable tube temperature.

FIND: (a) Maximum allowable heater current for adiabatic outer surface, (3) Effect of internal convection coefficient on heater temperature distribution, (c) Extent of heat loss at outer surface.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Constant properties, (3) Uniform heat generation, (4) Negligible radiation at outer surface, (5) Negligible contact resistance.

ANALYSIS: (a) From Eqs. 7 and 10, respectively, of Example 3.8, we know that

$$T_{s,2} - T_{s,1} = \frac{\dot{q}}{2k} r_2^2 \ln \frac{r_2}{r_1} - \frac{\dot{q}}{4k} (r_2^2 - r_1^2) \quad (1)$$

and

$$T_{s,1} = T_{\infty,1} + \frac{\dot{q} (r_2^2 - r_1^2)}{2h_1 r_1} \quad (2)$$

Hence, eliminating $T_{s,1}$, we obtain

$$T_{s,2} - T_{\infty,1} = \frac{\dot{q} r_2^2}{2k} \left[\ln \frac{r_2}{r_1} - \frac{1}{2} \left(1 - r_1^2 / r_2^2 \right) + \frac{k}{h_1 r_1} \left(1 - r_1^2 / r_2^2 \right) \right]$$

Substituting the prescribed conditions ($h_1 = 100 \text{ W/m}^2 \cdot \text{K}$),

$$T_{s,2} - T_{\infty,1} = 1.237 \times 10^{-4} \left(\text{m}^3 \cdot \text{K/W} \right) \dot{q} \left(\text{W/m}^3 \right)$$

Hence, with T_{\max} corresponding to $T_{s,2}$, the maximum allowable value of \dot{q} is

$$\dot{q}_{\max} = \frac{1400 - 400}{1.237 \times 10^{-4}} = 8.084 \times 10^6 \text{ W/m}^3$$

with

$$\dot{q} = \frac{I^2 \text{Re}}{\nabla} = \frac{I^2 \rho_e L / A_c}{L A_c} = \frac{\rho_e I^2}{\left[\pi (r_2^2 - r_1^2) \right]^2}$$

$$I_{\max} = \pi (r_2^2 - r_1^2) \left(\frac{\dot{q}}{\rho_e} \right)^{1/2} = \pi (0.035^2 - 0.025^2) \text{ m}^2 \left(\frac{8.084 \times 10^6 \text{ W/m}^3}{0.7 \times 10^{-6} \Omega \cdot \text{m}} \right)^{1/2} = 6406 \text{ A} <$$

Continued

PROBLEM 3.89 (Cont.)

(b) Using the one-dimensional, steady-state conduction model of *IHT* (hollow cylinder; convection at inner surface and adiabatic outer surface), the following temperature distributions were obtained.

The results are consistent with key implications of Eqs. (1) and (2), namely that the value of h_1 has no effect on the temperature drop across the tube ($T_{s,2} - T_{s,1} = 30$ K, irrespective of h_1), while $T_{s,1}$ decreases with increasing h_1 . For $h_1 = 100, 500$ and 1000 W/m²·K, respectively, the ratio of the temperature drop between the inner surface and the air to the temperature drop across the tube, $(T_{s,1} - T_{\infty,1})/(T_{s,2} - T_{s,1})$, decreases from $970/30 = 32.3$ to $194/30 = 6.5$ and $97/30 = 3.2$. Because the outer surface is insulated, the heat rate to the airflow is fixed by the value of \dot{q} and, irrespective of h_1 ,

$$\dot{q}'(l) = \pi(r_2^2 - r_1^2)\dot{q} = 15,240 \text{ W}$$

(c) Heat loss from the outer surface of the tube to the surroundings depends on the total thermal resistance

$$R_{\text{tot}} = \frac{\ln(r_3/r_2)}{2\pi L k_i} + \frac{1}{2\pi r_3 L h_2}$$

or, for a unit area on surface 2,

$$R_{\text{tot},2}^* = (2\pi r_2 L) R_{\text{tot}} = \frac{r_2 \ln(r_3/r_2)}{k_i} + \frac{r_2}{r_3 h_2}$$

Again using the capabilities of *IHT* (hollow cylinder; convection at inner surface and heat transfer from outer surface through $R_{\text{tot},2}^*$), the following temperature distributions were determined for the tube and insulation.

Continued...

PROBLEM 3.90

KNOWN: Electric current I is passed through a pipe of resistance R'_e to melt ice under steady-state conditions.

FIND: (a) Temperature distribution in the pipe wall, (b) Time to completely melt the ice.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Uniform heat generation in the pipe wall, (5) Outer surface of the pipe is adiabatic, (6) Inner surface is at a constant temperature, T_m .

PROPERTIES: Table A-3, Ice (273K): $\rho = 920\text{ kg/m}^3$; Handbook Chem. & Physics, Ice; Latent heat of fusion, $h_{sf} = 3.34 \times 10^5\text{ J/kg}$.

ANALYSIS: (a) The appropriate form of the heat equation is Eq. 3.49, and the general solution, Eq. 3.51 is

$$T(r) = -\frac{\dot{q}}{4k}r^2 + C_1 \ln r + C_2$$

where

$$\dot{q} = \frac{I^2 R'_e}{\pi(r_2^2 - r_1^2)}$$

Applying the boundary condition $dT/dr|_{r_2} = 0$, it follows that

$$0 = -\frac{\dot{q}r_2}{2k} + \frac{C_1}{r_2}$$

Hence
$$C_1 = \frac{\dot{q}r_2^2}{2k}$$

and
$$T(r) = -\frac{\dot{q}}{4k}r^2 + \frac{\dot{q}r_2^2}{2k} \ln r + C_2$$

Continued

PROBLEM 3.89 (Cont.)

Heat losses through the insulation, $q'(r_2)$, are 4250 and 3890 W/m for $\delta = 25$ and 50 mm, respectively, with corresponding values of $q'(r_1)$ equal to -10,990 and -11,350 W/m. Comparing the tube temperature distributions with those predicted for an adiabatic outer surface, it is evident that the losses reduce tube wall temperatures predicted for the adiabatic surface and also shift the maximum temperature from $r = 0.035$ m to $r \approx 0.033$ m. Although the tube outer and insulation inner surface temperatures, $T_{s,2} = T(r_2)$, increase with increasing insulation thickness, Fig. (c), the insulation outer surface temperature decreases.

COMMENTS: If the intent is to maximize heat transfer to the airflow, heat losses to the ambient should be reduced by selecting an insulation material with a significantly smaller thermal conductivity.

PROBLEM 3.91

KNOWN: Materials, dimensions, properties and operating conditions of a gas-cooled nuclear reactor.

FIND: (a) Inner and outer surface temperatures of fuel element, (b) Temperature distributions for different heat generation rates and maximum allowable generation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Negligible radiation.

PROPERTIES: Table A.1, Thorium: $T_{mp} \approx 2000$ K; Table A.2, Graphite: $T_{mp} \approx 2300$ K.

ANALYSIS: (a) The outer surface temperature of the fuel, T_2 , may be determined from the rate equation

$$q' = \frac{T_2 - T_\infty}{R'_{tot}}$$

where

$$R'_{tot} = \frac{\ln(r_3/r_2)}{2\pi k_g} + \frac{1}{2\pi r_3 h} = \frac{\ln(14/11)}{2\pi (3 \text{ W/m}\cdot\text{K})} + \frac{1}{2\pi (0.014 \text{ m})(2000 \text{ W/m}^2\cdot\text{K})} = 0.0185 \text{ m}\cdot\text{K/W}$$

and the heat rate per unit length may be determined by applying an energy balance to a control surface about the fuel element. Since the interior surface of the element is essentially adiabatic, it follows that

$$q' = \dot{q}\pi(r_2^2 - r_1^2) = 10^8 \text{ W/m}^3 \times \pi(0.011^2 - 0.008^2) \text{ m}^2 = 17,907 \text{ W/m}$$

Hence,

$$T_2 = q'R'_{tot} + T_\infty = 17,907 \text{ W/m}(0.0185 \text{ m}\cdot\text{K/W}) + 600 \text{ K} = 931 \text{ K}$$

With zero heat flux at the inner surface of the fuel element, Eq. C.14 yields

$$T_1 = T_2 + \frac{\dot{q}r_2^2}{4k_t} \left(1 - \frac{r_1^2}{r_2^2} \right) - \frac{\dot{q}r_1^2}{2k_t} \ln \left(\frac{r_2}{r_1} \right)$$

$$T_1 = 931 \text{ K} + \frac{10^8 \text{ W/m}^3 (0.011 \text{ m})^2}{4 \times 57 \text{ W/m}\cdot\text{K}} \left[1 - \left(\frac{0.008}{0.011} \right)^2 \right] - \frac{10^8 \text{ W/m}^3 (0.008 \text{ m})^2}{2 \times 57 \text{ W/m}\cdot\text{K}} \ln \left(\frac{0.011}{0.008} \right)$$

Continued...

PROBLEM 3.91 (Cont.)

$$T_1 = 931\text{ K} + 25\text{ K} - 18\text{ K} = 938\text{ K}$$

<

(b) The temperature distributions may be obtained by using the IHT model for one-dimensional, steady-state conduction in a hollow tube. For the fuel element ($\dot{q} > 0$), an adiabatic surface condition is prescribed at r_1 , while heat transfer from the outer surface at r_2 to the coolant is governed by the thermal resistance $R_{\text{tot},2} = 2\pi r_2 R_{\text{tot}} = 2\pi(0.011\text{ m})0.0185\text{ m}\cdot\text{K}/\text{W} = 0.00128\text{ m}^2\cdot\text{K}/\text{W}$. For the graphite ($\dot{q} = 0$), the value of T_2 obtained from the foregoing solution is prescribed as an inner boundary condition at r_2 , while a convection condition is prescribed at the outer surface (r_3). For $1 \times 10^8 \leq \dot{q} \leq 5 \times 10^8\text{ W/m}^3$, the following distributions are obtained.

The comparatively large value of k_f yields small temperature variations across the fuel element, while the small value of k_g results in large temperature variations across the graphite. Operation at $\dot{q} = 5 \times 10^8\text{ W/m}^3$ is clearly unacceptable, since the melting points of thorium and graphite are exceeded and approached, respectively. To prevent softening of the materials, which would occur below their melting points, the reactor should not be operated much above $\dot{q} = 3 \times 10^8\text{ W/m}^3$.

COMMENTS: A contact resistance at the thorium/graphite interface would increase temperatures in the fuel element, thereby reducing the maximum allowable value of \dot{q} .

PROBLEM 3.92

KNOWN: Long rod experiencing uniform volumetric generation encapsulated by a circular sleeve exposed to convection.

FIND: (a) Temperature at the interface between rod and sleeve and on the outer surface; (b) Temperature at center of rod.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction in rod and sleeve; (2) Steady-state conditions; (3) Uniform volumetric generation in rod; (4) Negligible contact resistance between rod and sleeve.

ANALYSIS: (a) Construct a thermal circuit for the sleeve;

where

$$q' = \dot{E}'_{gen} = \dot{q} \pi D_1^2 / 4 = 24,000 \text{ W/m}^3 \times \pi \times (0.20 \text{ m})^2 / 4 = 754.0 \text{ W/m}$$

$$R'_S = \frac{\ln(r_2/r_1)}{2\pi k_S} = \frac{\ln(400/200)}{2\pi \times 4 \text{ W/m}\cdot\text{K}} = 2.758 \times 10^{-2} \text{ m}\cdot\text{K/W}$$

$$R'_{conv} = \frac{1}{h\pi D_2} = \frac{1}{25 \text{ W/m}^2\cdot\text{K} \times \pi \times 0.400 \text{ m}} = 3.183 \times 10^{-2} \text{ m}\cdot\text{K/W}$$

The rate equation can be written as

$$q' = \frac{T_1 - T_\infty}{R'_S + R'_{conv}} = \frac{T_2 - T_\infty}{R'_{conv}}$$

$$T_1 = T_\infty + q'(R'_S + R'_{conv}) = 27^\circ\text{C} + 754 \text{ W/m} \left(2.758 \times 10^{-2} + 3.183 \times 10^{-2} \right) \text{ K/W}\cdot\text{m} = 71.8^\circ\text{C} <$$

$$T_2 = T_\infty + q'R'_{conv} = 27^\circ\text{C} + 754 \text{ W/m} \times 3.183 \times 10^{-2} \text{ m}\cdot\text{K/W} = 51.0^\circ\text{C} <$$

(b) The temperature at the center of the rod is

$$T(0) = T_o = \frac{\dot{q}r_1^2}{4k_R} + T_1 = \frac{24,000 \text{ W/m}^3 (0.100 \text{ m})^2}{4 \times 0.5 \text{ W/m}\cdot\text{K}} + 71.8^\circ\text{C} = 192^\circ\text{C} <$$

COMMENTS: The thermal resistances due to conduction in the sleeve and convection are comparable. Will increasing the sleeve outer diameter cause the surface temperature T_2 to increase or decrease?

PROBLEM 3.93

KNOWN: Radius, thermal conductivity, heat generation and convection conditions associated with a solid sphere.

FIND: Temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Uniform heat generation.

ANALYSIS: Integrating the appropriate form of the heat diffusion equation,

$$\frac{1}{r^2} \frac{d}{dr} \left[kr^2 \frac{dT}{dr} \right] + \dot{q} = 0 \quad \text{or} \quad \frac{d}{dr} \left[r^2 \frac{dT}{dr} \right] = -\frac{\dot{q}r^2}{k}$$

$$r^2 \frac{dT}{dr} = -\frac{\dot{q}r^3}{3k} + C_1 \quad \frac{dT}{dr} = -\frac{\dot{q}r}{3k} + \frac{C_1}{r^2}$$

$$T(r) = -\frac{\dot{q}r^2}{6k} - \frac{C_1}{r} + C_2.$$

The boundary conditions are: $\left. \frac{dT}{dr} \right|_{r=0} = 0$ hence $C_1 = 0$, and

$$\left. -k \frac{dT}{dr} \right|_{r=r_o} = h [T(r_o) - T_\infty].$$

Substituting into the second boundary condition ($r = r_o$), find

$$\frac{\dot{q}r_o}{3} = h \left[-\frac{\dot{q}r_o^2}{6k} + C_2 - T_\infty \right] \quad C_2 = \frac{\dot{q}r_o}{3h} + \frac{\dot{q}r_o^2}{6k} + T_\infty.$$

The temperature distribution has the form

$$T(r) = \frac{\dot{q}}{6k} (r_o^2 - r^2) + \frac{\dot{q}r_o}{3h} + T_\infty.$$

COMMENTS: To verify the above result, obtain $T(r_o) = T_s$,

$$T_s = \frac{\dot{q}r_o}{3h} + T_\infty$$

Applying energy balance to the control volume about the sphere,

$$\dot{q} \left[\frac{4}{3} \pi r_o^3 \right] = h 4\pi r_o^2 (T_s - T_\infty) \quad \text{find} \quad T_s = \frac{\dot{q}r_o}{3h} + T_\infty.$$

<

PROBLEM 3.94

KNOWN: Radial distribution of heat dissipation of a spherical container of radioactive wastes. Surface convection conditions.

FIND: Radial temperature distribution.

SCHEMATIC: _____

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across container wall.

ANALYSIS: The appropriate form of the heat equation is

$$\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{dT}{dr} \right) = -\frac{\dot{q}}{k} = -\frac{\dot{q}_o}{k} \left[1 - \left(\frac{r}{r_o} \right)^2 \right].$$

Hence

$$r^2 \frac{dT}{dr} = -\frac{\dot{q}_o}{k} \left(\frac{r^3}{3} - \frac{r^5}{5r_o^2} \right) + C_1$$

$$T = -\frac{\dot{q}_o}{k} \left(\frac{r^2}{6} - \frac{r^4}{20r_o^2} \right) - \frac{C_1}{r} + C_2.$$

From the boundary conditions,

$$dT/dr|_{r=0} = 0 \quad \text{and} \quad -k dT/dr|_{r=r_o} = h[T(r_o) - T_{\infty}]$$

it follows that $C_1 = 0$ and

$$\dot{q}_o \left(\frac{r_o}{3} - \frac{r_o}{5} \right) = h \left[-\frac{\dot{q}_o}{k} \left(\frac{r_o^2}{6} - \frac{r_o^2}{20} \right) + C_2 - T_{\infty} \right]$$

$$C_2 = \frac{2r_o \dot{q}_o}{15h} + \frac{7\dot{q}_o r_o^2}{60k} + T_{\infty}.$$

Hence

$$T(r) = T_{\infty} + \frac{2r_o \dot{q}_o}{15h} + \frac{\dot{q}_o r_o^2}{k} \left[\frac{7}{60} - \frac{1}{6} \left(\frac{r}{r_o} \right)^2 + \frac{1}{20} \left(\frac{r}{r_o} \right)^4 \right]. \quad <$$

COMMENTS: Applying the above result at r_o yields

$$T_s = T(r_o) = T_{\infty} + (2r_o \dot{q}_o / 15h).$$

The same result may be obtained by applying an energy balance to a control surface about the container, where $\dot{E}_g = q_{conv}$. The maximum temperature exists at $r = 0$.

PROBLEM 3.95

KNOWN: Dimensions and thermal conductivity of a spherical container. Thermal conductivity and volumetric energy generation within the container. Outer convection conditions.

FIND: (a) Outer surface temperature, (b) Container inner surface temperature, (c) Temperature distribution within and center temperature of the wastes, (d) Feasibility of operating at twice the energy generation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional radial conduction.

ANALYSIS: (a) For a control volume which includes the container, conservation of energy yields $\dot{E}_g - \dot{E}_{out} = 0$, or $\dot{q}V - q_{conv} = 0$. Hence

$$\dot{q} \left(\frac{4}{3} \right) (\pi r_i^3) = h 4 \pi r_o^2 (T_{s,o} - T_{\infty})$$

and with $\dot{q} = 10^5 \text{ W/m}^3$,

$$T_{s,o} = T_{\infty} + \frac{\dot{q} r_i^3}{3 h r_o^2} = 25^\circ \text{C} + \frac{10^5 \text{ W/m}^3 (0.5 \text{ m})^3}{3000 \text{ W/m}^2 \cdot \text{K} (0.6 \text{ m})^2} = 36.6^\circ \text{C}.$$

(b) Performing a surface energy balance at the outer surface, $\dot{E}_{in} - \dot{E}_{out} = 0$ or $q_{cond} - q_{conv} = 0$. Hence

$$\frac{4 \pi k_{ss} (T_{s,i} - T_{s,o})}{(1/r_i) - (1/r_o)} = h 4 \pi r_o^2 (T_{s,o} - T_{\infty})$$

$$T_{s,i} = T_{s,o} + \frac{h}{k_{ss}} \left(\frac{r_o}{r_i} - 1 \right) r_o (T_{s,o} - T_{\infty}) = 36.6^\circ \text{C} + \frac{1000 \text{ W/m}^2 \cdot \text{K}}{15 \text{ W/m} \cdot \text{K}} (0.2) 0.6 \text{ m} (11.6^\circ \text{C}) = 129.4^\circ \text{C}.$$

(c) The heat equation in spherical coordinates is

$$k_{rw} \frac{d}{dr} \left(r^2 \frac{dT}{dr} \right) + \dot{q} r^2 = 0.$$

Solving,

$$r^2 \frac{dT}{dr} = -\frac{\dot{q} r^3}{3 k_{rw}} + C_1 \quad \text{and} \quad T(r) = -\frac{\dot{q} r^2}{6 k_{rw}} - \frac{C_1}{r} + C_2$$

Applying the boundary conditions,

$$\left. \frac{dT}{dr} \right|_{r=0} = 0 \quad \text{and} \quad T(r_i) = T_{s,i}$$

$$C_1 = 0 \quad \text{and} \quad C_2 = T_{s,i} + \dot{q} r_i^2 / 6 k_{rw}.$$

Continued...

PROBLEM 3.95 (Cont.)

Hence

$$T(r) = T_{s,i} + \frac{\dot{q}}{6k_{rw}}(r_i^2 - r^2) \quad <$$

At $r = 0$,

$$T(0) = T_{s,i} + \frac{\dot{q}r_i^2}{6k_{rw}} = 129.4^\circ\text{C} + \frac{10^5 \text{ W/m}^3 (0.5 \text{ m})^2}{6(20 \text{ W/m}\cdot\text{K})} = 337.7^\circ\text{C} \quad <$$

(d) The feasibility assessment may be performed by using the IHT model for one-dimensional, steady-state conduction in a solid sphere, with the surface boundary condition prescribed in terms of the total thermal resistance

$$R''_{\text{tot},i} = \left(4\pi r_i^2\right) R_{\text{tot}} = R''_{\text{cnd},i} + R''_{\text{cnv},i} = \frac{r_i^2 \left[(1/r_i) - (1/r_o) \right]}{k_{ss}} + \frac{1}{h} \left(\frac{r_i}{r_o} \right)^2$$

where, for $r_o = 0.6 \text{ m}$ and $h = 1000 \text{ W/m}^2\cdot\text{K}$, $R''_{\text{cnd},i} = 5.56 \times 10^{-3} \text{ m}^2\cdot\text{K/W}$, $R''_{\text{cnv},i} = 6.94 \times 10^{-4} \text{ m}^2\cdot\text{K/W}$, and $R''_{\text{tot},i} = 6.25 \times 10^{-3} \text{ m}^2\cdot\text{K/W}$. Results for the center temperature are shown below.

Clearly, even with $r_o = 0.54 \text{ m} = r_{o,\text{min}}$ and $h = 10,000 \text{ W/m}^2\cdot\text{K}$ (a practical upper limit), $T(0) > 475^\circ\text{C}$ and the desired condition can not be met. The corresponding resistances are $R''_{\text{cnd},i} = 2.47 \times 10^{-3} \text{ m}^2\cdot\text{K/W}$, $R''_{\text{cnv},i} = 8.57 \times 10^{-5} \text{ m}^2\cdot\text{K/W}$, and $R''_{\text{tot},i} = 2.56 \times 10^{-3} \text{ m}^2\cdot\text{K/W}$. The conduction resistance remains dominant, and the effect of reducing $R''_{\text{cnv},i}$ by increasing h is small. *The proposed extension is not feasible.*

COMMENTS: A value of $\dot{q} = 1.79 \times 10^5 \text{ W/m}^3$ would allow for operation at $T(0) = 475^\circ\text{C}$ with $r_o = 0.54 \text{ m}$ and $h = 10,000 \text{ W/m}^2\cdot\text{K}$.

PROBLEM 3.96

KNOWN: Carton of apples, modeled as 80-mm diameter spheres, ventilated with air at 5°C and experiencing internal volumetric heat generation at a rate of 4000 J/kg·day.

FIND: (a) The apple center and surface temperatures when the convection coefficient is 7.5 W/m²·K, and (b) Compute and plot the apple temperatures as a function of air velocity, V , for the range $0.1 \leq V \leq 1$ m/s, when the convection coefficient has the form $h = C_1 V^{0.425}$, where $C_1 = 10.1$ W/m²·K·(m/s)^{0.425}.

SCHEMATIC:

ASSUMPTIONS: (1) Apples can be modeled as spheres, (2) Each apple experiences flow of ventilation air at $T_\infty = 5^\circ\text{C}$, (3) One-dimensional radial conduction, (4) Constant properties and (5) Uniform heat generation.

ANALYSIS: (a) From Eq. C.24, the temperature distribution in a solid sphere (apple) with uniform generation is

$$T(r) = \frac{\dot{q} r_o^2}{6k} \left(1 - \frac{r^2}{r_o^2} \right) + T_s \quad (1)$$

To determine T_s , perform an energy balance on the apple as shown in the sketch above, with volume $V = 4/3 \pi r_o^3$,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g &= 0 & -q_{\text{cv}} + \dot{q}V &= 0 \\ -h(4\pi r_o^2)(T_s - T_\infty) + \dot{q}(4\pi r_o^3/3) &= 0 & (2) \\ -7.5 \text{ W/m}^2 \cdot \text{K} (4\pi \times 0.040^2 \text{ m}^2)(T_s - 5^\circ\text{C}) + 38.9 \text{ W/m}^3 (4\pi \times 0.040^3 \text{ m}^3/3) &= 0 \end{aligned}$$

where the volumetric generation rate is

$$\dot{q} = 4000 \text{ J/kg} \cdot \text{day}$$

$$\dot{q} = 4000 \text{ J/kg} \cdot \text{day} \times 840 \text{ kg/m}^3 \times (1 \text{ day}/24 \text{ hr}) \times (1 \text{ hr}/3600 \text{ s})$$

$$\dot{q} = 38.9 \text{ W/m}^3$$

and solving for T_s , find

$$T_s = 5.14^\circ\text{C} \quad <$$

From Eq. (1), at $r = 0$, with T_s , find

$$T(0) = \frac{38.9 \text{ W/m}^3 \times 0.040^2 \text{ m}^2}{6 \times 0.5 \text{ W/m} \cdot \text{K}} + 5.14^\circ\text{C} = 0.12^\circ\text{C} + 5.14^\circ\text{C} = 5.26^\circ\text{C} \quad <$$

Continued...

PROBLEM 3.96 (Cont.)

(b) With the convection coefficient depending upon velocity,

$$h = C_1 V^{0.425}$$

with $C_1 = 10.1 \text{ W/m}^2 \cdot \text{K} \cdot (\text{m/s})^{0.425}$, and using the energy balance of Eq. (2), calculate and plot T_s as a function of ventilation air velocity V . With very low velocities, the center temperature is nearly 0.5°C higher than the air. From our earlier calculation we know that $T(0) - T_s = 0.12^\circ\text{C}$ and is independent of V .

COMMENTS: (1) While the temperature within the apple is nearly isothermal, the center temperature will track the ventilation air temperature which will increase as it passes through stacks of cartons.

(2) The *IHT* Workspace used to determine T_s for the base condition and generate the above plot is shown below.

```
// The temperature distribution, Eq (1),
T_r = qdot * ro^2 / (4 * k) * ( 1 - r^2/ro^2 ) + Ts

// Energy balance on the apple, Eq (2)
- qcv + qdot * Vol = 0
Vol = 4 / 3 * pi * ro ^3

// Convection rate equation:
qcv = h * As * ( Ts - Tinf )
As = 4 * pi * ro^2

// Generation rate:
qdot = qdotm * (1/24) * (1/3600) * rho           // Generation rate, W/m^3; Conversions: days/h and h/sec

// Assigned variables:
ro = 0.080                                     // Radius of apple, m
k = 0.5                                         // Thermal conductivity, W/m.K
qdotm = 4000                                   // Generation rate, J/kg.K
rho = 840                                       // Specific heat, J/kg.K
r = 0                                           // Center, m; location for T(0)
h = 7.5                                         // Convection coefficient, W/m^2.K; base case, V = 0.5 m/s
// h = C1 * V^0.425                             // Correlation
// C1 = 10.1
// V = 0.5                                       // Air velocity, m/s; range 0.1 to 1 m/s
Tinf = 5                                        // Air temperature, C
```

PROBLEM 3.97

KNOWN: Plane wall, long cylinder and sphere, each with characteristic length a , thermal conductivity k and uniform volumetric energy generation rate \dot{q} .

FIND: (a) On the same graph, plot the dimensionless temperature, $[T(x \text{ or } r) - T(a)] / [\dot{q} a^2 / 2k]$, vs. the dimensionless characteristic length, x/a or r/a , for each shape; (b) Which shape has the smallest temperature difference between the center and the surface? Explain this behavior by comparing the ratio of the volume-to-surface area; and (c) Which shape would be preferred for use as a nuclear fuel element? Explain why?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties and (4) Uniform volumetric generation.

ANALYSIS: (a) For each of the shapes, with $T(a) = T_s$, the dimensionless temperature distributions can be written by inspection from results in Appendix C.3.

Plane wall, Eq. C.22

$$\frac{T(x) - T_s}{\dot{q} a^2 / 2k} = 1 - \left(\frac{x}{a} \right)^2$$

Long cylinder, Eq. C.23

$$\frac{T(r) - T_s}{\dot{q} a^2 / 2k} = \frac{1}{2} \left[1 - \left(\frac{r}{a} \right)^2 \right]$$

Sphere, Eq. C.24

$$\frac{T(r) - T_s}{\dot{q} a^2 / 2k} = \frac{1}{3} \left[1 - \left(\frac{r}{a} \right)^2 \right]$$

The dimensionless temperature distributions using the foregoing expressions are shown in the graph below.

Continued

PROBLEM 3.97 (Cont.)

(b) The sphere shape has the smallest temperature difference between the center and surface, $T(0) - T(a)$. The ratio of volume-to-surface-area, \forall/A_s , for each of the shapes is

$$\text{Plane wall} \quad \frac{\forall}{A_s} = \frac{a(1 \times 1)}{(1 \times 1)} = a$$

$$\text{Long cylinder} \quad \frac{\forall}{A_s} = \frac{\pi a^2 \times 1}{2\pi a \times 1} = \frac{a}{2}$$

$$\text{Sphere} \quad \frac{\forall}{A_s} = \frac{4\pi a^3/3}{4\pi a^2} = \frac{a}{3}$$

The smaller the \forall/A_s ratio, the smaller the temperature difference, $T(0) - T(a)$.

(c) The sphere would be the preferred element shape since, for a given \forall/A_s ratio, which controls the generation and transfer rates, the sphere will operate at the lowest temperature.

PROBLEM 3.98

KNOWN: Radius, thickness, and incident flux for a radiation heat gauge.

FIND: Expression relating incident flux to temperature difference between center and edge of gauge.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r (negligible temperature drop across foil thickness), (3) Constant properties, (4) Uniform incident flux, (5) Negligible heat loss from foil due to radiation exchange with enclosure wall, (6) Negligible contact resistance between foil and heat sink.

ANALYSIS: Applying energy conservation to a circular ring extending from r to $r + dr$,

$$q_r + q_i''(2\pi r dr) = q_{r+dr}, \quad q_r = -k(2\pi r t) \frac{dT}{dr}, \quad q_{r+dr} = q_r + \frac{dq_r}{dr} dr.$$

Rearranging, find that

$$q_i''(2\pi r dr) = \frac{d}{dr} \left[(-k2\pi r t) \frac{dT}{dr} \right] dr$$

$$\frac{d}{dr} \left[r \frac{dT}{dr} \right] = -\frac{q_i''}{kt} r.$$

Integrating,

$$r \frac{dT}{dr} = -\frac{q_i'' r^2}{2kt} + C_1 \quad \text{and} \quad T(r) = -\frac{q_i'' r^2}{4kt} + C_1 \ln r + C_2.$$

With $dT/dr|_{r=0} = 0$, $C_1 = 0$ and with $T(r = R) = T(R)$,

$$T(R) = -\frac{q_i'' R^2}{4kt} + C_2 \quad \text{or} \quad C_2 = T(R) + \frac{q_i'' R^2}{4kt}.$$

Hence, the temperature distribution is

$$T(r) = \frac{q_i''}{4kt} (R^2 - r^2) + T(R).$$

Applying this result at $r = 0$, it follows that

$$q_i'' = \frac{4kt}{R^2} [T(0) - T(R)] = \frac{4kt}{R^2} \Delta T.$$

<

COMMENTS: This technique allows for determination of a radiation flux from measurement of a temperature difference. It becomes inaccurate if emission from the foil becomes significant.

PROBLEM 3.99

KNOWN: Net radiative flux to absorber plate.

FIND: (a) Maximum absorber plate temperature, (b) Rate of energy collected per tube.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional (x) conduction along absorber plate, (3) Uniform radiation absorption at plate surface, (4) Negligible losses by conduction through insulation, (5) Negligible losses by convection at absorber plate surface, (6) Temperature of absorber plate at $x = 0$ is approximately that of the water.

PROPERTIES: Table A-1, Aluminum alloy (2024-T6): $k \approx 180 \text{ W/m}\cdot\text{K}$.

ANALYSIS: The absorber plate acts as an extended surface (a conduction-radiation system), and a differential equation which governs its temperature distribution may be obtained by applying Eq.1.11b to a differential control volume. For a unit length of tube

$$q'_x + q''_{\text{rad}}(dx) - q'_{x+dx} = 0.$$

With $q'_{x+dx} = q'_x + \frac{dq'_x}{dx} dx$

and $q'_x = -kt \frac{dT}{dx}$

it follows that,

$$q''_{\text{rad}} - \frac{d}{dx} \left[-kt \frac{dT}{dx} \right] = 0$$

$$\frac{d^2 T}{dx^2} + \frac{q''_{\text{rad}}}{kt} = 0$$

Integrating twice it follows that, the general solution for the temperature distribution has the form,

$$T(x) = -\frac{q''_{\text{rad}}}{2kt} x^2 + C_1 x + C_2.$$

Continued

PROBLEM 3.99 (Cont.)

The boundary conditions are:

$$\begin{aligned} T(0) &= T_w & C_2 &= T_w \\ \left. \frac{dT}{dx} \right|_{x=L/2} &= 0 & C_1 &= \frac{q''_{\text{rad}} L}{2kt} \end{aligned}$$

Hence,

$$T(x) = \frac{q''_{\text{rad}}}{2kt} x(L-x) + T_w.$$

The maximum absorber plate temperature, which is at $x = L/2$, is therefore

$$T_{\text{max}} = T(L/2) = \frac{q''_{\text{rad}} L^2}{8kt} + T_w.$$

The rate of energy collection per tube may be obtained by applying Fourier's law at $x = 0$. That is, energy is transferred to the tubes via conduction through the absorber plate. Hence,

$$q' = 2 \left[-k t \left. \frac{dT}{dx} \right|_{x=0} \right]$$

where the factor of two arises due to heat transfer from both sides of the tube. Hence,

$$q' = -Lq''_{\text{rad}}.$$

Hence

$$T_{\text{max}} = \frac{800 \frac{\text{W}}{\text{m}^2} (0.2\text{m})^2}{8 \left[180 \frac{\text{W}}{\text{m} \cdot \text{K}} \right] (0.006\text{m})} + 60^\circ \text{C}$$

or $T_{\text{max}} = 63.7^\circ \text{C}$ <

and $q' = -0.2\text{m} \times 800 \text{ W/m}^2$

or $q' = -160 \text{ W/m}$. <

COMMENTS: Convection losses in the typical flat plate collector, which is not evacuated, would reduce the value of q' .

PROBLEM 3.100

KNOWN: Surface conditions and thickness of a solar collector absorber plate. Temperature of working fluid.

FIND: (a) Differential equation which governs plate temperature distribution, (b) Form of the temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Adiabatic bottom surface, (4) Uniform radiation flux and convection coefficient at top, (5) Temperature of absorber plate at $x = 0$ corresponds to that of working fluid.

ANALYSIS: (a) Performing an energy balance on the differential control volume,

$$q'_x + dq'_{rad} = q'_{x+dx} + dq'_{conv}$$

where
$$\begin{aligned} q'_{x+dx} &= q'_x + (dq'_x/dx)dx \\ dq'_{rad} &= q''_{rad} \cdot dx \\ dq'_{conv} &= h(T - T_\infty) \cdot dx \end{aligned}$$

Hence,
$$q''_{rad}dx = (dq'_x/dx)dx + h(T - T_\infty)dx.$$

From Fourier's law, the conduction heat rate per unit width is

$$q'_x = -k t dT/dx \quad \frac{d^2T}{dx^2} - \frac{h}{kT}(T - T_\infty) - \frac{q''_{rad}}{kt} = 0. \quad <$$

(b) Defining $\theta = T - T_\infty$, $d^2T/dx^2 = d^2\theta/dx^2$ and the differential equation becomes,

$$\frac{d^2\theta}{dx^2} - \frac{h}{kt}\theta + \frac{q''_{rad}}{kt} = 0.$$

It is a second-order, differential equation with constant coefficients and a source term, and its general solution is of the form

$$\theta = C_1 e^{+\lambda x} + C_2 e^{-\lambda x} + S/\lambda^2$$

where $\lambda = (h/kt)^{1/2}$, $S = q''_{rad}/kt$.

Appropriate boundary conditions are:

$$\theta(0) = T_0 - T_\infty = \theta_0, \quad d\theta/dx|_{x=L} = 0.$$

Hence,
$$\theta_0 = C_1 + C_2 + S/\lambda^2$$

$$d\theta/dx|_{x=L} = C_1 \lambda e^{+\lambda L} - C_2 \lambda e^{-\lambda L} = 0 \quad C_2 = C_1 e^{2\lambda L}$$

Hence,
$$C_1 = (\theta_0 - S/\lambda^2) / (1 + e^{2\lambda L}) \quad C_2 = (\theta_0 - S/\lambda^2) / (1 + e^{-2\lambda L})$$

$$\theta = (\theta_0 - S/\lambda^2) \left[\frac{e^{\lambda x}}{1 + e^{2\lambda L}} + \frac{e^{-\lambda x}}{1 + e^{-2\lambda L}} \right] + S/\lambda^2. \quad <$$

PROBLEM 3.101

KNOWN: Dimensions of a plate insulated on its bottom and thermally joined to heat sinks at its ends. Net heat flux at top surface.

FIND: (a) Differential equation which determines temperature distribution in plate, (b) Temperature distribution and heat loss to heat sinks.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction in x ($W, L \gg t$), (3) Constant properties, (4) Uniform surface heat flux, (5) Adiabatic bottom, (6) Negligible contact resistance.

ANALYSIS: (a) Applying conservation of energy to the differential control volume, $q_x + dq = q_{x+dx}$, where $q_{x+dx} = q_x + (dq_x/dx) dx$ and $dq = q_0'' (W \cdot dx)$. Hence, $(dq_x/dx) - q_0'' W = 0$. From Fourier's law, $q_x = -k(t \cdot W) dT/dx$. Hence, the differential equation for the temperature distribution is

$$-\frac{d}{dx} \left[ktW \frac{dT}{dx} \right] - q_0'' W = 0 \quad \frac{d^2 T}{dx^2} + \frac{q_0''}{kt} = 0. \quad <$$

(b) Integrating twice, the general solution is,

$$T(x) = -\frac{q_0''}{2kt} x^2 + C_1 x + C_2$$

and appropriate boundary conditions are $T(0) = T_0$, and $T(L) = T_0$. Hence, $T_0 = C_2$, and

$$T_0 = -\frac{q_0''}{2kt} L^2 + C_1 L + C_2 \quad \text{and} \quad C_1 = \frac{q_0'' L}{2kt}.$$

Hence, the temperature distribution is

$$T(x) = -\frac{q_0''}{2kt} (x^2 - Lx) + T_0. \quad <$$

Applying Fourier's law at $x = 0$, and at $x = L$,

$$q(0) = -k(Wt) \left. \frac{dT}{dx} \right|_{x=0} = -kWt \left[-\frac{q_0''}{kt} \right] \left[x - \frac{L}{2} \right] \bigg|_{x=0} = -\frac{q_0'' WL}{2}$$

$$q(L) = -k(Wt) \left. \frac{dT}{dx} \right|_{x=L} = -kWt \left[-\frac{q_0''}{kt} \right] \left[x - \frac{L}{2} \right] \bigg|_{x=L} = +\frac{q_0'' WL}{2}$$

Hence the heat loss from the plates is $q = 2(q_0'' WL/2) = q_0'' WL$. <

COMMENTS: (1) Note signs associated with $q(0)$ and $q(L)$. (2) Note symmetry about $x = L/2$. Alternative boundary conditions are $T(0) = T_0$ and $dT/dx|_{x=L/2} = 0$.

PROBLEM 3.102

KNOWN: Dimensions and surface conditions of a plate thermally joined at its ends to heat sinks at different temperatures. Heat flux into top of plate. Convection conditions beneath plate.

FIND: (a) Differential equation which determines temperature distribution in plate, (b) Temperature distribution and an expression for the heat rate from the plate to the sinks, and (c) Compute and plot temperature distribution and heat rates corresponding to changes in different parameters.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x ($W, L \gg t$), (3) Constant properties, (4) Uniform surface heat flux and convection coefficient, (5) Negligible contact resistance.

ANALYSIS: (a) Applying conservation of energy to the differential control volume

$$q_x + dq_o = q_{x+dx} + dq_{conv}$$

where

$$q_{x+dx} = q_x + (dq_x/dx)dx \quad dq_{conv} = h(T - T_\infty)(W \cdot dx)$$

Hence,

$$q_x + q_o''(W \cdot dx) = q_x + (dq_x/dx)dx + h(T - T_\infty)(W \cdot dx) \quad \frac{dq_x}{dx} + hW(T - T_\infty) = q_o''W.$$

Using Fourier's law, $q_x = -k(t \cdot W)dT/dx$,

$$-ktW \frac{d^2T}{dx^2} + hW(T - T_\infty) = q_o''W \quad \frac{d^2T}{dx^2} - \frac{h}{kt}(T - T_\infty) + \frac{q_o''}{kt} = 0. \quad <$$

(b) Introducing $\theta \equiv T - T_\infty$, the differential equation becomes

$$\frac{d^2\theta}{dx^2} - \frac{h}{kt}\theta + \frac{q_o''}{kt} = 0.$$

This differential equation is of second order with constant coefficients and a source term. With

$\lambda^2 \equiv h/kt$ and $S \equiv q_o''/kt$, it follows that the general solution is of the form

$$\theta = C_1 e^{+\lambda x} + C_2 e^{-\lambda x} + S/\lambda^2. \quad (1)$$

Appropriate boundary conditions are: $\theta(0) = T_o - T_\infty \equiv \theta_o$ $\theta(L) = T_L - T_\infty \equiv \theta_L$ (2,3)

Substituting the boundary conditions, Eqs. (2,3) into the general solution, Eq. (1),

$$\theta_o = C_1 e^0 + C_2 e^0 + S/\lambda^2 \quad \theta_L = C_1 e^{+\lambda L} + C_2 e^{-\lambda L} + S/\lambda^2 \quad (4,5)$$

To solve for C_2 , multiply Eq. (4) by $-e^{+\lambda L}$ and add the result to Eq. (5),

$$-\theta_o e^{+\lambda L} + \theta_L = C_2 (-e^{+\lambda L} + e^{-\lambda L}) + S/\lambda^2 (-e^{+\lambda L} + 1) \\ C_2 = \left[(\theta_L - \theta_o e^{+\lambda L}) - S/\lambda^2 (-e^{+\lambda L} + 1) \right] / (-e^{+\lambda L} + e^{-\lambda L}) \quad (6)$$

Continued...

PROBLEM 3.102 (Cont.)

Substituting for C_2 from Eq. (6) into Eq. (4), find

$$C_1 = \theta_o - \left\{ \left[\left(\theta_L - \theta_o e^{+\lambda L} \right) - S/\lambda^2 \left(-e^{+\lambda L} + 1 \right) \right] / \left(-e^{+\lambda L} + e^{-\lambda L} \right) \right\} - S/\lambda^2 \quad (7)$$

Using C_1 and C_2 from Eqs. (6,7) and Eq. (1), the temperature distribution can be expressed as

$$\theta(x) = \left[e^{+\lambda x} - \frac{\sinh(\lambda x)}{\sinh(\lambda L)} e^{+\lambda L} \right] \theta_o + \frac{\sinh(\lambda x)}{\sinh(\lambda L)} \theta_L + \left[- \left(1 - e^{+\lambda L} \right) \frac{\sinh(\lambda x)}{\sinh(\lambda L)} + \left(1 - e^{+\lambda x} \right) \right] \frac{S}{\lambda^2} \quad (8)$$

The heat rate from the plate is $q_p = -q_x(0) + q_x(L)$ and using Fourier's law, the conduction heat rates, with $A_c = W \cdot t$, are

$$q_x(0) = -kA_c \left(\frac{d\theta}{dx} \right)_{x=0} = -kA_c \left\{ \left[\lambda e^0 - \frac{e^{\lambda L}}{\sinh(\lambda L)} \lambda \right] \theta_o + \frac{\lambda}{\sinh(\lambda L)} \theta_L + \left[- \frac{1 - e^{+\lambda L}}{\sinh(\lambda L)} \lambda - \lambda \right] \frac{S}{\lambda^2} \right\} <$$

$$q_x(L) = -kA_c \left(\frac{d\theta}{dx} \right)_{x=L} = -kA_c \left\{ \left[\lambda e^{\lambda L} - \frac{e^{\lambda L}}{\sinh(\lambda L)} \lambda \cosh(\lambda L) \right] \theta_o + \frac{\lambda \cosh(\lambda L)}{\sinh(\lambda L)} \theta_L + \left[- \frac{1 - e^{+\lambda L}}{\sinh(\lambda L)} \lambda \cosh(\lambda L) - \lambda e^{+\lambda L} \right] \frac{S}{\lambda^2} \right\} <$$

(c) For the prescribed base-case conditions listed below, the temperature distribution (solid line) is shown in the accompanying plot. As expected, the maximum temperature does not occur at the midpoint, but slightly toward the x-origin. The sink heat rates are

$$q_x''(0) = -17.22 \text{ W} \quad q_x''(L) = 23.62 \text{ W} \quad <$$

The additional temperature distributions on the plot correspond to changes in the following parameters, with all the remaining parameters unchanged: (i) $q_o'' = 30,000 \text{ W/m}^2$, (ii) $h = 200 \text{ W/m}^2 \cdot \text{K}$, (iii) the value of q_o'' for which $q_x''(0) = 0$ with $h = 200 \text{ W/m}^2 \cdot \text{K}$. The condition for the last curve is $q_o'' = 4927 \text{ W/m}^2$ for which the temperature gradient at $x = 0$ is zero.

Base case conditions are: $q_o'' = 20,000 \text{ W/m}^2$, $T_o = 100^\circ\text{C}$, $T_L = 35^\circ\text{C}$, $T_\infty = 25^\circ\text{C}$, $k = 25 \text{ W/m} \cdot \text{K}$, $h = 50 \text{ W/m}^2 \cdot \text{K}$, $L = 100 \text{ mm}$, $t = 5 \text{ mm}$, $W = 30 \text{ mm}$.

PROBLEM 3.103

KNOWN: Thin plastic film being bonded to a metal strip by laser heating method; strip dimensions and thermophysical properties are prescribed as are laser heating flux and convection conditions.

FIND: (a) Expression for temperature distribution for the region with the plastic strip, $-w_1/2 \leq x \leq w_1/2$, (b) Temperature at the center ($x = 0$) and the edge of the plastic strip ($x = \pm w_1/2$) when the laser flux is $10,000 \text{ W/m}^2$; (c) Plot the temperature distribution for the strip and point out special features.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x-direction only, (3) Plastic film has negligible thermal resistance, (4) Upper and lower surfaces have uniform convection coefficients, (5) Edges of metal strip are at air temperature (T_∞), that is, strip behaves as infinite fin so that $w_2 \rightarrow \infty$, (6) All the incident laser heating flux q_0'' is absorbed by the film, (7) Negligible radiation heat transfer.

PROPERTIES: Metal strip (given): $\rho = 7850 \text{ kg/m}^3$, $c_p = 435 \text{ J/kg} \cdot \text{m}^3$, $k = 60 \text{ W/m} \cdot \text{K}$.

ANALYSIS: (a) The strip-plastic film arrangement can be modeled as an infinite fin of uniform cross section a portion of which is exposed to the laser heat flux on the upper surface. The general solutions for the two regions of the strip, in terms of $\theta \equiv T(x) - T_\infty$, are

$$0 \leq x \leq w_1/2 \quad \theta_1(x) = C_1 e^{+mx} + C_2 e^{-mx} + M/m^2 \quad (1)$$

$$M = q_0'' P / 2kA_c = q_0'' / kd \quad m = (2h/kd)^{1/2} \quad (2,3)$$

$$w_1/2 \leq x \leq \infty \quad \theta_2(x) = C_3 e^{+mx} + C_4 e^{-mx} \quad (4)$$

Four boundary conditions can be identified to evaluate the constants:

$$\text{At } x = 0: \quad \frac{d\theta_1}{dx}(0) = 0 = C_1 m e^0 - C_2 m e^{-0} + 0 \rightarrow C_1 = C_2 \quad (5)$$

$$\begin{aligned} \text{At } x = w_1/2: \quad \theta(w_1/2) &= \theta_1(w_1/2) \\ C_1 e^{+mw_1/2} + C_2 e^{-mw_1/2} + M/m^2 &= C_3 e^{+mw_1/2} + C_4 e^{-mw_1/2} \end{aligned} \quad (6)$$

$$\begin{aligned} \text{At } x = w_1/2: \quad d\theta_1(w_1/2)/dx &= d\theta_2(w_1/2)/dx \\ mC_1 e^{+mw_1/2} - mC_2 e^{-mw_1/2} + 0 &= mC_3 e^{+mw_1/2} - mC_4 e^{-mw_1/2} \end{aligned} \quad (7)$$

$$\text{At } x \rightarrow \infty: \quad \theta_2(\infty) = 0 = C_3 e^{\infty} + C_4 e^{-\infty} \rightarrow C_3 = 0 \quad (8)$$

With $C_3 = 0$ and $C_1 = C_2$, combine Eqs. (6 and 7) to eliminate C_4 to find

$$C_1 = C_2 = -\frac{M/m^2}{2e^{mw_1/2}} \quad (9)$$

and using Eq. (6) with Eq. (9) find

$$C_4 = M/m^2 \sinh(mw_1/2) e^{-mw_1/2} \quad (10)$$

Continued...

PROBLEM 3.103 (Cont.)

Hence, the temperature distribution in the region (1) under the plastic film, $0 \leq x \leq w_1/2$, is

$$\theta_1(x) = \frac{M/m^2}{2e^{mw_1/2}} (e^{+mx} + e^{-mx}) + \frac{M}{m^2} = \frac{M}{m^2} \left(1 - e^{-mw_1/2} \cosh mx \right) \quad (11)$$

and for the region (2), $x \geq w_1/2$,

$$\theta_2(x) = \frac{M}{m^2} \sinh(mw_1/2) e^{-mx} \quad (12)$$

(b) Substituting numerical values into the temperature distribution expression above, $\theta_1(0)$ and $\theta_1(w_1/2)$ can be determined. First evaluate the following parameters:

$$M = 10,000 \text{ W/m}^2 / 60 \text{ W/m} \cdot \text{K} \times 0.00125 \text{ m} = 133.333 \text{ K/m}^2$$

$$m = \left(2 \times 10 \text{ W/m}^2 \cdot \text{K} / 60 \text{ W/m} \cdot \text{K} \times 0.00125 \text{ m} \right)^{1/2} = 16.33 \text{ m}^{-1}$$

Hence, for the midpoint $x = 0$,

$$\theta_1(0) = \frac{133.333 \text{ K/m}^2}{(16.33 \text{ m}^{-1})^2} \left[1 - \exp(-16.33 \text{ m}^{-1} \times 0.020 \text{ m}) \right] \cosh(0) = 139.3 \text{ K}$$

$$T_1(0) = \theta_1(0) + T_\infty = 139.3 \text{ K} + 25^\circ\text{C} = 164.3^\circ\text{C}$$

For the position $x = w_1/2 = 0.020 \text{ m}$,

$$\theta_1(w_1/2) = 500.0 \left[1 - 0.721 \cosh(16.33 \text{ m}^{-1} \times 0.020 \text{ m}) \right] = 120.1 \text{ K}$$

$$T_1(w_1/2) = 120.1 \text{ K} + 25^\circ\text{C} = 145.1^\circ\text{C}$$

(c) The temperature distributions, $\theta_1(x)$ and $\theta_2(x)$, are shown in the plot below. Using IHT, Eqs. (11) and (12) were entered into the workspace and a graph created. The special features are noted:

(1) No gradient at midpoint, $x = 0$; symmetrical distribution.

(2) No discontinuity of gradient at $w_1/2$ (20 mm).

(3) Temperature excess and gradient approach zero with increasing value of x .

COMMENTS: How wide must the strip be in order to satisfy the infinite fin approximation such that $\theta_2(x \rightarrow \infty) = 0$? For $x = 200 \text{ mm}$, find $\theta_2(200 \text{ mm}) = 6.3^\circ\text{C}$, this would be a poor approximation. When $x = 300 \text{ mm}$, $\theta_2(300 \text{ mm}) = 1.2^\circ\text{C}$; hence when $w_2/2 = 300 \text{ mm}$, the strip is a reasonable approximation to an infinite fin.

PROBLEM 3.104

KNOWN: Thermal conductivity, diameter and length of a wire which is annealed by passing an electrical current through the wire.

FIND: Steady-state temperature distribution along wire.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction along the wire, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient h .

ANALYSIS: Applying conservation of energy to a differential control volume,

$$q_x + \dot{E}_g - dq_{\text{conv}} - q_{x+dx} = 0$$

$$q_{x+dx} = q_x + \frac{dq_x}{dx} dx \quad q_x = -k \left(\pi D^2 / 4 \right) dT/dx$$

$$dq_{\text{conv}} = h \left(\pi D dx \right) (T - T_\infty) \quad \dot{E}_g = \dot{q} \left(\pi D^2 / 4 \right) dx.$$

Hence,

$$k \left(\pi D^2 / 4 \right) \frac{d^2 T}{dx^2} dx + \dot{q} \left(\pi D^2 / 4 \right) dx - h \left(\pi D dx \right) (T - T_\infty) = 0$$

or, with $\theta \equiv T - T_\infty$,

$$\frac{d^2 \theta}{dx^2} - \frac{4h}{kD} \theta + \frac{\dot{q}}{k} = 0$$

The solution (general and particular) to this nonhomogeneous equation is of the form

$$\theta = C_1 e^{mx} + C_2 e^{-mx} + \frac{\dot{q}}{km^2}$$

where $m^2 = (4h/kD)$. The boundary conditions are:

$$\left. \frac{d\theta}{dx} \right|_{x=0} = 0 = m C_1 e^0 - m C_2 e^0 \rightarrow C_1 = C_2$$

$$\theta(L) = 0 = C_1 \left(e^{mL} + e^{-mL} \right) + \frac{\dot{q}}{km^2} \rightarrow C_1 = \frac{-\dot{q}/km^2}{e^{mL} + e^{-mL}} = C_2$$

The temperature distribution has the form

$$T = T_\infty - \frac{\dot{q}}{km^2} \left[\frac{e^{mx} + e^{-mx}}{e^{mL} + e^{-mL}} - 1 \right] = T_\infty - \frac{\dot{q}}{km^2} \left[\frac{\cosh mx}{\cosh mL} - 1 \right]. \quad <$$

COMMENTS: This process is commonly used to anneal wire and spring products. To check the result, note that $T(L) = T(-L) = T_\infty$.

PROBLEM 3.105

KNOWN: Electric power input and mechanical power output of a motor. Dimensions of housing, mounting pad and connecting shaft needed for heat transfer calculations. Temperature of ambient air, tip of shaft, and base of pad.

FIND: Housing temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in pad and shaft, (3) Constant properties, (4) Negligible radiation.

ANALYSIS: Conservation of energy yields

$$P_{elec} - P_{mech} - q_h - q_p - q_s = 0$$

$$q_h = h_h A_h (T_h - T_\infty), \quad q_p = k_p W^2 \frac{(T_h - T_\infty)}{t}, \quad q_s = M \frac{\cosh mL - \theta_L / \theta_b}{\sinh mL}$$

$$\theta_L = 0, \quad mL = \left(4h_s L^2 / k_s D \right)^{1/2}, \quad M = \left(\frac{\pi^2}{4} D^3 h_s k_s \right)^{1/2} (T_h - T_\infty).$$

Hence

$$q_s = \frac{\left(\left[\pi^2 / 4 \right] D^3 h_s k_s \right)^{1/2} (T_h - T_\infty)}{\tanh \left(4h_s L^2 / k_s D \right)^{1/2}}$$

Substituting, and solving for $(T_h - T_\infty)$,

$$T_h - T_\infty = \frac{P_{elec} - P_{mech}}{h_h A_h + k_p W^2 / t + \left(\left(\pi^2 / 4 \right) D^3 h_s k_s \right)^{1/2} / \tanh \left(4h_s L^2 / k_s D \right)^{1/2}}$$

$$\left(\left(\pi^2 / 4 \right) D^3 h_s k_s \right)^{1/2} = 6.08 \text{ W/K}, \quad \left(4h_s L^2 / k_s D \right)^{1/2} = 3.87, \quad \tanh mL = 0.999$$

$$T_h - T_\infty = \frac{(25 - 15) \times 10^3 \text{ W}}{\left[10 \times 2 + 0.5(0.7)^2 / 0.05 + 6.08 / 0.999 \right] \text{ W/K}} = \frac{10^4 \text{ W}}{(20 + 4.90 + 6.15) \text{ W/K}}$$

$$T_h - T_\infty = 322.1 \text{ K} \quad T_h = 347.1^\circ \text{C}$$

<

COMMENTS: (1) T_h is large enough to provide significant heat loss by radiation from the housing. Assuming an emissivity of 0.8 and surroundings at 25°C , $q_{rad} = \varepsilon A_h (T_h^4 - T_{sur}^4) = 4347 \text{ W}$, which compares with $q_{conv} = h_h A_h (T_h - T_\infty) = 5390 \text{ W}$. Radiation has the effect of decreasing T_h . (2) The infinite fin approximation, $q_s = M$, is excellent.

PROBLEM 3.106

KNOWN: Dimensions, convective conditions, bipolar plate, hydrogen and air temperatures within a fuel cell.

FIND: (a) The differential equation governing the membrane temperature distribution, $T(x)$, (b) Solution of the equation of part (a), (c) Temperature distributions associated with carbon nanotube loadings of 0 and 10 volume percent.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Uniform volumetric energy generation, (4) Negligible contact resistance.

ANALYSIS:

(a) Performing an energy balance on the differential control volume,

$$\begin{aligned} q'_x + dq'_g &= q'_{x+dx} + dq'_{conv,a} + dq'_{conv,h} \\ q'_{x+dx} &= q'_x + (dq'_x/dx)dx \end{aligned} \quad (1)$$

where $dq'_g = \dot{q} \cdot t \cdot dx$, $dq'_{conv,a} = h_a(T - T_a)dx$, $dq'_{conv,h} = h_h(T - T_h)dx$

Noting that $T_a = T_h$, Eq. (1) becomes

$$\dot{q} \cdot t \cdot dx = (dq'_x/dx)dx + h_a(T - T_a)dx + h_h(T - T_h)dx = (dq'_x/dx)dx + [(h_a + h_h)(T - T_h)]dx$$

From Fourier's law,

$$q'_x = -kt \, dT/dx$$

$$\text{and} \quad \frac{d^2T}{dx^2} - \frac{1}{k_{eff,x}t}[(h_a + h_h)(T - T_a)] + \frac{\dot{q}}{k_{eff,x}} = 0 \quad <$$

Continued...

PROBLEM 3.106 (Cont.)

(b) Defining $\theta = T - T_a$ and $\frac{d^2T}{dx^2} = \frac{d^2\theta}{dx^2}$, the differential equation becomes

$$\frac{d^2\theta}{dx^2} - \frac{(h_a + h_h)}{k_{\text{eff},x}t} \theta + \frac{\dot{q}}{k_{\text{eff},x}} = 0$$

This is the second-order, differential equation, and its general solution is of the form

$$\theta = C_1 e^{+\lambda x} + C_2 e^{-\lambda x} + S / \lambda^2$$

$$\text{where } \lambda = \left(\frac{h_a + h_h}{k_{\text{eff},x}t} \right)^{1/2}, \quad S = \frac{\dot{q}}{k_{\text{eff},x}}$$

Appropriate boundary conditions are:

$$\theta(0) = T_0 - T_a = \theta_0, \quad d\theta/dx|_{x=L} = 0.$$

$$\text{Hence, } \theta_0 = C_1 + C_2 + S/\lambda^2$$

$$d\theta/dx|_{x=L} = C_1 \lambda e^{+\lambda L} - C_2 \lambda e^{-\lambda L} = 0 \quad C_2 = C_1 e^{2\lambda L}$$

$$\text{Hence, } C_1 = (\theta_0 - S/\lambda^2) / (1 + e^{2\lambda L}) \quad C_2 = (\theta_0 - S/\lambda^2) / (1 + e^{-2\lambda L})$$

$$\theta = (\theta_0 - S/\lambda^2) \left[\frac{e^{\lambda x}}{1 + e^{2\lambda L}} + \frac{e^{-\lambda x}}{1 + e^{-2\lambda L}} \right] + S/\lambda^2. \quad <$$

(c) For $h_a = 35 \text{ W/m}^2 \cdot \text{K}$, $h_h = 235 \text{ W/m}^2 \cdot \text{K}$ and $k_{\text{eff},x} = 0.79 \text{ W/m} \cdot \text{K}$

$$\lambda = \left[\frac{35 \text{ W/m}^2 \cdot \text{K} + 235 \text{ W/m}^2 \cdot \text{K}}{0.79 \text{ W/m} \cdot \text{K} \times 0.42 \times 10^{-3} \text{ m}} \right]^{1/2} = 902 \text{ m}^{-1}$$

$$\text{For } \dot{q} = 10 \times 10^6 \text{ W/m}^3, \quad S = \frac{10 \times 10^6 \text{ W/m}^3}{0.79 \text{ W/m} \cdot \text{K}} = 12.7 \times 10^6 \text{ K/m}^2$$

The temperature distribution without, and with carbon nanotube loading, is shown below. <

Continued...

PROBLEM 3.106 (Cont.)

Without carbon nanotube loading.

With carbon nanotube loading.

COMMENTS: (1) The carbon nanotubes are effective in reducing the maximum temperature of the membrane. (2) Contact resistances between the bipolar plates and the membrane can be large. Hence, the actual membrane temperature will be higher than indicated with this analysis.

PROBLEM 3.107

KNOWN: TC wire leads attached to the upper and lower surfaces of a cylindrically shaped solder bead. Base of bead attached to cylinder head operating at 350°C . Constriction resistance at base and TC wire convection conditions specified.

FIND: (a) Thermal circuit that can be used to determine the temperature difference between the two intermediate metal TC junctions, $(T_1 - T_2)$; label temperatures, thermal resistances and heat rates; and (b) Evaluate $(T_1 - T_2)$ for the prescribed conditions. Comment on assumptions made in building the model.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in solder bead; no losses from lateral and top surfaces; (3) TC wires behave as infinite fins, (4) Negligible thermal contact resistance between TC wire terminals and bead.

ANALYSIS: (a) The thermal circuit is shown above. Note labels for the temperatures, thermal resistances and the relevant heat fluxes. The thermal resistances are as follows:

Constriction (con) resistance, see Table 4.1, case 10

$$R_{\text{con}} = 1 / (2k_{\text{head}} D_{\text{sol}}) = 1 / (2 \times 40 \text{ W/m} \cdot \text{K} \times 0.006 \text{ m}) = 2.08 \text{ K/W}$$

TC (tc) wires, infinitely long fins; Eq. 3.80

$$R_{\text{tc},1} = R_{\text{tc},2} = R_{\text{fin}} = (hPk_w A_c)^{-0.5} \quad P = \pi D_w, A_c = \pi D_w^2 / 4$$

$$R_{\text{tc}} = \left(100 \text{ W/m}^2 \cdot \text{K} \times \pi^2 \times (0.003 \text{ m})^3 \times 70 \text{ W/m} \cdot \text{K} / 4 \right)^{-0.5} = 46.31 \text{ K/W}$$

Solder bead (sol), cylinder D_{sol} and L_{sol}

$$R_{\text{sol}} = L_{\text{sol}} / (k_{\text{sol}} A_{\text{sol}}) \quad A_{\text{sol}} = \pi D_{\text{sol}}^2 / 4$$

$$R_{\text{sol}} = 0.010 \text{ m} / \left(10 \text{ W/m} \cdot \text{K} \times \pi (0.006 \text{ m})^2 / 4 \right) = 35.37 \text{ K/W}$$

(b) Perform energy balances on the 1- and 2-nodes, solve the equations simultaneously to find T_1 and T_2 , from which $(T_1 - T_2)$ can be determined.

Continued

PROBLEM 3.107 (Cont.)

$$\text{Node 1} \quad \frac{T_2 - T_1}{R_{\text{sol}}} + \frac{T_{\text{head}} - T_1}{R_{\text{con}}} + \frac{T_{\infty} - T_1}{R_{\text{tc},1}} = 0$$

$$\text{Node 2} \quad \frac{T_{\infty} - T_2}{R_{\text{tc},2}} + \frac{T_1 - T_2}{R_{\text{sol}}} = 0$$

Substituting numerical values with the equations in the *IHT* Workspace, find

$$T_1 = 359^{\circ}\text{C} \quad T_2 = 199.2^{\circ}\text{C} \quad T_1 - T_2 = 160^{\circ}\text{C}$$

COMMENTS: (1) With this arrangement, the TC indicates a systematically low reading of the cylinder head. The size of the solder bead (L_{sol}) needs to be reduced substantially.

(2) The model neglects heat losses from the top and lateral sides of the solder bead, the effect of which would be to increase our estimate for $(T_1 - T_2)$. Constriction resistance is important; note that $T_{\text{head}} - T_1 = 26^{\circ}\text{C}$.

PROBLEM 3.108

KNOWN: Rod ($D, k, 2L$) that is perfectly insulated over the portion of its length $-L \leq x \leq 0$ and experiences convection (T_∞, h) over the portion $0 \leq x \leq +L$. One end is maintained at T_1 and the other is separated from a heat sink at T_3 with an interfacial thermal contact resistance R_{tc}'' .

FIND: (a) Sketch the temperature distribution T vs. x and identify key features; assume $T_1 > T_3 > T_2$; (b) Derive an expression for the mid-point temperature T_2 in terms of thermal and geometric parameters of the system, (c) Using numerical values, calculate T_2 and plot the temperature distribution. Describe key features and compare to your sketch of part (a).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in rod for $-L \leq x \leq 0$, (3) Rod behaves as one-dimensional extended surface for $0 \leq x \leq +L$, (4) Constant properties.

ANALYSIS: (a) The sketch for the temperature distribution is shown below. Over the insulated portion of the rod, the temperature distribution is linear. A temperature drop occurs across the thermal contact resistance at $x = +L$. The distribution over the exposed portion of the rod is non-linear. The minimum temperature of the system could occur in this portion of the rod.

(b) To derive an expression for T_2 , begin with the general solution from the conduction analysis for a fin of uniform cross-sectional area, Eq. 3.66.

$$\theta(x) = C_1 e^{mx} + C_2 e^{-mx} \quad 0 \leq x \leq +L \quad (1)$$

where $m = (hP/kA_c)^{1/2}$ and $\theta = T(x) - T_\infty$. The arbitrary constants are determined from the boundary conditions.

At $x = 0$, thermal resistance of rod

$$q_x(0) = -kA_c \left. \frac{d\theta}{dx} \right|_{x=0} = kA_c \frac{\theta_1 - \theta(0)}{L} \quad \theta_1 = T_1 - T_\infty$$

$$-\left[m C_1 e^0 - m C_2 e^0 \right] = \frac{1}{L} \left[\theta_1 - (C_1 e^0 + C_2 e^0) \right] \quad (2)$$

Continued

PROBLEM 3.108 (Cont.)

At $x=L$, thermal contact resistance

$$q_x(+L) = -kA_c \left. \frac{d\theta}{dx} \right|_{x=L} = \frac{\theta(L) - \theta_3}{R''_{tc} / A_c} \quad \theta_3 = T_3 - T_\infty$$

$$-k \left[m C_1 e^{mL} - m C_2 e^{-mL} \right] = \frac{1}{R''_{tc}} \left[C_1 e^{mL} + C_2 e^{-mL} - \theta_3 \right] \quad (3)$$

Eqs. (2) and (3) cannot be rearranged easily to find explicit forms for C_1 and C_2 . The constraints will be evaluated numerically in part (c). Knowing C_1 and C_2 , Eq. (1) gives

$$\theta_2 = \theta(0) = T_2 - T_\infty = C_1 e^0 + C_2 e^0 \quad (4)$$

(c) With Eqs. (1-4) in the *IHT Workspace* using numerical values shown in the schematic, find $T_2 = 62.1^\circ\text{C}$. The temperature distribution is shown in the graph below.

COMMENTS: (1) The purpose of asking you to sketch the temperature distribution in part (a) was to give you the opportunity to identify the relevant thermal processes and come to an understanding of the system behavior.

(2) Sketch the temperature distributions for the following conditions and explain their key features:

(a) $R''_{tc} = 0$, (b) $R''_{tc} \rightarrow \infty$, and (c) the exposed portion of the rod behaves as an infinitely long fin; that is, k is very large.

PROBLEM 3.109

KNOWN: Diameter and base temperature of a silicon carbide nanowire, required temperature of the catalyst tip.

FIND: Maximum length of a nanowire that may be grown under specified conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Nanowire stops growing when $T_c = T(x = L) = 3000$ K, (2) Constant properties, (3) One-dimensional heat transfer, (4) Convection from the tip of the nanowire, (5) Nanowire grows very slowly, (6) Negligible impact of nanoscale heat transfer effects.

PROPERTIES: Table A.2, silicon carbide (1500 K): $k = 30$ W/m·K.

ANALYSIS: The tip of the nanowire is initially at $T = 2400$ K, and increases in temperature as the nanowire becomes longer. At steady-state, the tip reaches $T = 3000$ K. The temperature distribution at steady-state is given by Eq. 3.70:

$$\frac{\theta}{\theta_b} = \frac{\cosh m(L - x) + (h / mk) \sinh m(L - x)}{\cosh mL + (h / mk) \sinh mL} \quad (1)$$

where

$$m = \left(\frac{hP}{kA_c} \right)^{1/2} = \left(\frac{4h}{kD} \right)^{1/2} = \left(\frac{4 \times 10^5 \text{ W/m}^2 \cdot \text{K}}{30 \text{ W/m} \cdot \text{K} \times 15 \times 10^{-9} \text{ m}} \right)^{1/2} = 943 \times 10^3 \text{ m}^{-1}$$

and

$$\frac{h}{mk} = \frac{10^5 \text{ W/m}^2 \cdot \text{K}}{943 \times 10^3 \text{ m}^{-1} \times 30 \text{ W/m} \cdot \text{K}} = 3.53 \times 10^{-3}$$

Equation 1, evaluated at $x = L$, is

$$\frac{\theta}{\theta_b} = \frac{(3000 - 8000) \text{ K}}{(2400 - 8000) \text{ K}} = 0.893 = \frac{1}{\cosh(943 \times 10^3 \times L) + 3.53 \times 10^{-3} \sinh(943 \times 10^3 \times L)}$$

A trial-and-error solution yields $L = 510 \times 10^{-9} \text{ m} = 510 \text{ nm}$

<

Continued...

PROBLEM 3.109 (Cont.)

COMMENTS: (1) The importance of radiation heat transfer may be ascertained by evaluating Eq. 1.9. Assuming large surroundings at a temperature of $T_{\text{sur}} = 8000 \text{ K}$ and an emissivity of unity, the radiation heat transfer coefficient at the fin tip is

$$\begin{aligned} h_r &= \varepsilon \sigma (T(x=L) + T_{\text{sur}}) \left[T^2(x=L) + T_{\text{sur}}^2 \right] \\ &= 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (3000 \text{ K} + 8000 \text{ K}) \times \left[(3000 \text{ K})^2 + (8000 \text{ K})^2 \right] = 4.5 \times 10^4 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

We see that $h_r < h$, but radiation may be important. (2) The thermal conductivity has been evaluated at 1500 K and extrapolated to a much higher temperature. More accurate values of the thermal conductivity, accounting for the high temperature and possible nanoscale heat transfer effects, are desirable. (3) If the nanowire were to grow rapidly, the transient temperature distribution within the nanowire would need to be evaluated.

PROBLEM 3.110

KNOWN: Temperature sensing probe of thermal conductivity k , length L and diameter D is mounted on a duct wall; portion of probe L_i is exposed to water stream at $T_{\infty,i}$ while other end is exposed to ambient air at $T_{\infty,o}$; convection coefficients h_i and h_o are prescribed.

FIND: (a) Expression for the measurement error, $\Delta T_{\text{err}} = T_{\text{tip}} - T_{\infty,i}$, (b) For prescribed $T_{\infty,i}$ and $T_{\infty,o}$, calculate ΔT_{err} for immersion to total length ratios of 0.225, 0.425, and 0.625, (c) Compute and plot the effects of probe thermal conductivity and water velocity (h_i) on ΔT_{err} .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in probe, (3) Probe is thermally isolated from the duct, (4) Convection coefficients are uniform over their respective regions.

PROPERTIES: Probe material (given): $k = 177 \text{ W/m} \cdot \text{K}$.

ANALYSIS: (a) To derive an expression for $\Delta T_{\text{err}} = T_{\text{tip}} - T_{\infty,i}$, we need to determine the temperature distribution in the immersed length of the probe $T_i(x)$. Consider the probe to consist of two regions: $0 \leq x_i \leq L_i$, the immersed portion, and $0 \leq x_o \leq (L - L_i)$, the ambient-air portion where the origin corresponds to the location of the duct wall. Use the results for the temperature distribution and fin heat rate of Case A, Table 3.4:

Temperature distribution in region i :

$$\frac{\theta_i}{\theta_{b,i}} = \frac{T_i(x_i) - T_{\infty,i}}{T_o - T_{\infty,i}} = \frac{\cosh(m_i(L_i - x_i)) + (h_i/m_i k) \sinh(L_i - x_i)}{\cosh(m_i L_i) + (h_i/m_i k) \sinh(m_i L_i)} \quad (1)$$

and the tip temperature, $T_{\text{tip}} = T_i(L_i)$ at $x_i = L_i$, is

$$\frac{T_{\text{tip}} - T_{\infty,i}}{T_o - T_{\infty,i}} = A = \frac{\cosh(0) + (h_i/m_i k) \sinh(0)}{\cosh(m_i L_i) + (h_i/m_i k) \sinh(m_i L_i)} \quad (2)$$

and hence

$$\Delta T_{\text{err}} = T_{\text{tip}} - T_{\infty,i} = A(T_o - T_{\infty,i}) \quad (3)$$

where T_o is the temperature at $x_i = x_o = 0$ which at present is unknown, but can be found by setting the fin heat rates equal, that is,

$$q_{f,o} = -q_{f,i} \quad (4)$$

Continued...

PROBLEM 3.110 (Cont.)

$$(h_o P k A_c)^{1/2} \theta_{b,o} \cdot B = -(h_i P k A_c)^{1/2} \theta_{b,i} \cdot C$$

Solving for T_o , find

$$\frac{\theta_{b,o}}{\theta_{b,i}} = \frac{T_o - T_{\infty,o}}{T_o - T_{\infty,i}} = - \frac{(h_i P k A_c)^{1/2} C}{(h_o P k A_c)^{1/2} B} = - \left(\frac{h_i}{h_o} \right)^{1/2} \frac{C}{B}$$

$$T_o = \left[T_{\infty,o} + \left(\frac{h_i}{h_o} \right)^{1/2} \frac{C}{B} T_{\infty,i} \right] / \left[1 + \left(\frac{h_i}{h_o} \right)^{1/2} \frac{C}{B} \right] \quad (5)$$

where the constants B and C are,

$$B = \frac{\sinh(m_o L_o) + (h_o/m_o k) \cosh(m_o L_o)}{\cosh(m_o L_o) + (h_o/m_o k) \sinh(m_o L_o)} \quad (6)$$

$$C = \frac{\sinh(m_i L_i) + (h_i/m_i k) \cosh(m_i L_i)}{\cosh(m_i L_i) + (h_i/m_i k) \sinh(m_i L_i)} \quad (7)$$

(b) To calculate the immersion error for prescribed immersion lengths, $L_i/L = 0.225, 0.425$ and 0.625 , we use Eq. (3) as well as Eqs. (2, 6, 7 and 5) for A, B, C, and T_o , respectively. Results of these calculations are summarized below.

L_i/L	L_o (mm)	L_i (mm)	A	B	C	T_o (°C)	ΔT_{err} (°C)	
0.225	155	45	0.2328	0.5865	0.9731	76.7	-0.76	<
0.425	115	85	0.0396	0.4639	0.992	77.5	-0.10	<
0.625	75	125	0.0067	0.3205	0.9999	78.2	-0.01	<

(c) The probe behaves as a fin having ends exposed to the cool ambient air and the hot ambient water whose temperature is to be measured. As shown above, the probe is more accurate when more of its length is exposed to the water. If the thermal conductivity is *decreased*, heat transfer along the probe length is likewise decreased, the tip temperature will be closer to the water temperature. If the velocity of the water *decreases*, the convection coefficient will decrease, and the difference between the tip and water temperatures will increase.

PROBLEM 3.111

KNOWN: Rod protruding normally from a furnace wall covered with insulation of thickness L_{ins} with the length L_o exposed to convection with ambient air.

FIND: (a) An expression for the exposed surface temperature T_o as a function of the prescribed thermal and geometrical parameters. (b) Will a rod of $L_o = 100$ mm meet the specified operating limit, $T_o \leq 100^\circ\text{C}$? If not, what design parameters would you change?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in rod, (3) Negligible thermal contact resistance between the rod and hot furnace wall, (4) Insulated section of rod, L_{ins} , experiences no lateral heat losses, (5) Convection coefficient uniform over the exposed portion of the rod, L_o , (6) Adiabatic tip condition for the rod and (7) Negligible radiation exchange between rod and its surroundings.

ANALYSIS: (a) The rod can be modeled as a thermal network comprised of two resistances in series: the portion of the rod, L_{ins} , covered by insulation, R_{ins} , and the portion of the rod, L_o , experiencing convection, and behaving as a fin with an adiabatic tip condition, R_{fin} . For the insulated section:

$$R_{ins} = L_{ins} / kA_c \quad (1)$$

For the fin, Table 3.4, Case B, Eq. 3.76,

$$R_{fin} = \theta_b / q_f = \frac{1}{(hPkA_c)^{1/2} \tanh(mL_o)} \quad (2)$$

$$m = (hP/kA_c)^{1/2} \quad A_c = \pi D^2/4 \quad P = \pi D \quad (3,4,5)$$

From the thermal network, by inspection,

$$\frac{T_o - T_\infty}{R_{fin}} = \frac{T_w - T_\infty}{R_{ins} + R_{fin}} \quad T_o = T_\infty + \frac{R_{fin}}{R_{ins} + R_{fin}} (T_w - T_\infty) \quad (6) <$$

(b) Substituting numerical values into Eqs. (1) - (6) with $L_o = 200$ mm,

$$T_o = 25^\circ\text{C} + \frac{6.298}{6.790 + 6.298} (200 - 25)^\circ\text{C} = 109^\circ\text{C} <$$

$$R_{ins} = \frac{0.200 \text{ m}}{60 \text{ W/m} \cdot \text{K} \times 4.909 \times 10^{-4} \text{ m}^2} = 6.790 \text{ K/W} \quad A_c = \pi (0.025 \text{ m})^2 / 4 = 4.909 \times 10^{-4} \text{ m}^2$$

$$R_{fin} = 1 / \left((0.0347 \text{ W}^2/\text{K}^2) \right)^{1/2} \tanh(6.324 \times 0.200) = 6.298 \text{ K/W}$$

$$(hPkA_c) = \left(15 \text{ W/m}^2 \cdot \text{K} \times \pi (0.025 \text{ m}) \times 60 \text{ W/m} \cdot \text{K} \times 4.909 \times 10^{-4} \text{ m}^2 \right) = 0.0347 \text{ W}^2/\text{K}^2$$

Continued...

PROBLEM 3.111 (Cont.)

$$m = (hP/kA_c)^{1/2} = \left(15 \text{ W/m}^2 \cdot \text{K} \times \pi (0.025 \text{ m}) / 60 \text{ W/m} \cdot \text{K} \times 4.909 \times 10^{-4} \text{ m}^2\right)^{1/2} = 6.324 \text{ m}^{-1}$$

Consider the following design changes aimed at reducing $T_o \leq 100^\circ\text{C}$. (1) Increasing length of the fin portions: with $L_o = 400$ and 600 mm, T_o is 102.8°C and 102.3°C , respectively. Hence, increasing L_o will reduce T_o only modestly. (2) Decreasing the thermal conductivity: backsolving the above equation set with $T_o = 100^\circ\text{C}$, find the required thermal conductivity is $k = 14 \text{ W/m}\cdot\text{K}$. Hence, we could select a stainless steel alloy; see Table A.1. (3) Increasing the insulation thickness: find that for $T_o = 100^\circ\text{C}$, the required insulation thickness would be $L_{\text{ins}} = 211$ mm. This design solution might be physically and economically unattractive. (4) A very practical solution would be to introduce thermal contact resistance between the rod base and the furnace wall by “tack welding” (rather than a continuous bead around the rod circumference) the rod in two or three places. (5) A less practical solution would be to increase the convection coefficient, since to do so, would require an air handling unit. (6) Using a tube rather than a rod will decrease A_c . For a 3 mm tube wall and 25 mm outside diameter, $A_c = 2.07 \times 10^{-4} \text{ m}^2$, $R_{\text{ins}} = 16.103 \text{ K/W}$ and $R_{\text{fin}} = 8.61 \text{ K/W}$, yielding $T_o = 86^\circ\text{C}$. (conduction within the air inside the tube is neglected).

COMMENTS: (1) Would replacing the rod by a thick-walled tube provide a practical solution?

(2) The *IHT Thermal Resistance Network Model* and the *Thermal Resistance Tool* for a *fin* with an *adiabatic tip* were used to create a model of the rod. The Workspace is shown below.

// Thermal Resistance Network Model:

// The Network:

// Heat rates into node j,q[j], through thermal resistance R[ij]

q21 = (T2 - T1) / R21

q32 = (T3 - T2) / R32

// Nodal energy balances

q1 + q21 = 0

q2 - q21 + q32 = 0

q3 - q32 = 0

/* Assigned variables list: deselect the qi, R[ij] and Ti which are unknowns; set qi = 0 for embedded nodal points at which there is no external source of heat. */

T1 = Tw // Furnace wall temperature, C

//q1 = // Heat rate, W

T2 = To // To, beginning of rod exposed length

q2 = 0 // Heat rate, W; node 2; no external heat source

T3 = Tinf // Ambient air temperature, C

//q3 = // Heat rate, W

// Thermal Resistances:

// Rod - conduction resistance

R21 = Lins / (k * Ac) // Conduction resistance, K/W

Ac = pi * D^2 / 4 // Cross sectional area of rod, m^2

// Thermal Resistance Tools - Fin with Adiabatic Tip:

R32 = Rfin // Resistance of fin, K/W

/* Thermal resistance of a fin of uniform cross sectional area Ac, perimeter P, length L, and thermal conductivity k with an adiabatic tip condition experiencing convection with a fluid at Tinf and coefficient h, */

Rfin = 1 / (tanh (m*L_o) * (h * P * k * Ac) ^ (1/2)) // Case B, Table 3.4

m = sqrt(h * P / (k * Ac))

P = pi * D // Perimeter, m

// Other Assigned Variables:

Tw = 200 // Furnace wall temperature, C

k = 60 // Rod thermal conductivity, W/m.K

Lins = 0.200 // Insulated length, m

D = 0.025 // Rod diameter, m

h = 15 // Convection coefficient, W/m^2.K

Tinf = 25 // Ambient air temperature, C

Lo = 0.200 // Exposed length, m

PROBLEM 3.112

KNOWN: Rod ($D, k, 2L$) inserted into a perfectly insulating wall, exposing one-half of its length to an airstream (T_∞, h). An electromagnetic field induces a uniform volumetric energy generation (\dot{q}) in the imbedded portion.

FIND: (a) Derive an expression for T_b at the base of the exposed half of the rod; the exposed region may be approximated as a very long fin; (b) Derive an expression for T_o at the end of the imbedded half of the rod, and (c) Using numerical values, plot the temperature distribution in the rod and describe its key features. Does the rod behave as a very long fin?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in imbedded portion of rod, (3) Imbedded portion of rod is perfectly insulated, (4) Exposed portion of rod behaves as an infinitely long fin, and (5) Constant properties.

ANALYSIS: (a) Since the exposed portion of the rod ($0 \leq x \leq +L$) behaves as an infinite fin, the fin heat rate using Eq. 3.80 is

$$q_x(0) = q_f = M = (hPkA_c)^{1/2} (T_b - T_\infty) \quad (1)$$

From an energy balance on the imbedded portion of the rod,

$$q_f = \dot{q} A_c L \quad (2)$$

Combining Eqs. (1) and (2), with $P = \pi D$ and $A_c = \pi D^2/4$, find

$$T_b = T_\infty + q_f (hPkA_c)^{-1/2} = T_\infty + \dot{q} A_c^{1/2} L (hPk)^{-1/2} \quad (3) <$$

(b) The imbedded portion of the rod ($-L \leq x \leq 0$) experiences one-dimensional heat transfer with uniform \dot{q} . From Eq. 3.43,

$$T_o = \frac{\dot{q} L^2}{2k} + T_b \quad <$$

(c) The temperature distribution $T(x)$ for the rod is piecewise parabolic and exponential,

$$T(x) - T_b = \frac{\dot{q} L^2}{2k} \left(\frac{x}{L} \right)^2 \quad -L \leq x \leq 0$$

$$\frac{T(x) - T_\infty}{T_b - T_\infty} = \exp(-mx) \quad 0 \leq x \leq +L$$

where $m = (hP/kA_c)^{1/2}$.

Continued

PROBLEM 3.112 (Cont.)

The gradient at $x = 0$ will be continuous since we used this condition in evaluating T_b . The distribution is shown below with $T_o = 105.4^\circ\text{C}$ and $T_b = 55.4^\circ\text{C}$.

COMMENTS: The assumption that the rod behaves as an infinitely long fin is accurate; we see from the figure above that the temperature approaches the ambient temperature near the end of the rod.

PROBLEM 3.113

KNOWN: Very long rod (D, k) subjected to induction heating experiences uniform volumetric generation (\dot{q}) over the center, 30-mm long portion. The unheated portions experience convection (T_∞, h).

FIND: Calculate the temperature of the rod at the mid-point of the heated portion within the coil, T_o , and at the edge of the heated portion, T_b .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with uniform \dot{q} in portion of rod within the coil; no convection from lateral surface of rod, (3) Exposed portions of rod behave as infinitely long fins, and (4) Constant properties, (5) Neglect radiation.

ANALYSIS: The portion of the rod within the coil, $0 \leq x \leq L$, experiences one-dimensional conduction with uniform generation. From Eq. 3.43,

$$T_o = \frac{\dot{q}L^2}{2k} + T_b \quad (1)$$

The portion of the rod beyond the coil, $L \leq x \leq \infty$, behaves as an infinitely long fin for which the heat rate from Eq. 3.80 is

$$q_f = q_x(L) = (hPkA_c)^{1/2} (T_b - T_\infty) \quad (2)$$

where $P = \pi D$ and $A_c = \pi D^2/4$. From an overall energy balance on the imbedded portion of the rod as illustrated in the schematic above, find the heat rate as

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} &= 0 \\ -q_f + \dot{q}A_cL &= 0 \\ q_f &= \dot{q}A_cL \end{aligned} \quad (3)$$

Combining Eqs. (1-3),

$$T_b = T_\infty + \dot{q}A_c^{1/2}L(hPk)^{-1/2} \quad (4)$$

$$T_o = T_\infty + \frac{\dot{q}L^2}{2k} + \dot{q}A_c^{1/2}L(hPk)^{-1/2} \quad (5)$$

and substituting numerical values find

$$T_o = 305^\circ\text{C} \quad T_b = 272^\circ\text{C} \quad <$$

COMMENT: Assuming $\varepsilon = 0.8$ and $T_{\text{sur}} = T_\infty = 20^\circ\text{C}$, $h_{\text{rad}} = 14.6 \text{ W/m}^2\text{-K}$. Hence, radiation is significant and would serve to substantially reduce both T_o and T_b .

PROBLEM 3.114

KNOWN: Dimensions, end temperatures and volumetric heating of wire leads. Convection coefficient and ambient temperature.

FIND: (a) Equation governing temperature distribution in the leads, (b) Form of the temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction in x , (3) Uniform volumetric heating, (4) Uniform h (both sides), (5) Negligible radiation, (6) Constant properties.

ANALYSIS: (a) Performing an energy balance for the differential control volume,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0 \quad q_x - q_{x+dx} - dq_{conv} + \dot{q}dV = 0$$

$$-kA_c \frac{dT}{dx} - \left[-kA_c \frac{dT}{dx} - \frac{d}{dx} \left(kA_c \frac{dT}{dx} \right) dx \right] - hPdx(T - T_\infty) + \dot{q}A_c dx = 0$$

$$\frac{d^2T}{dx^2} - \frac{hP}{kA_c}(T - T_\infty) + \frac{\dot{q}}{k} = 0$$

<

(b) With a *reduced temperature* defined as $\Theta \equiv T - T_\infty - (\dot{q}A_c/hP)$ and $m^2 \equiv hP/kA_c$, the differential equation may be rendered homogeneous, with a general solution and boundary conditions as shown

$$\frac{d^2\Theta}{dx^2} - m^2\Theta = 0 \quad \Theta(x) = C_1 e^{mx} + C_2 e^{-mx}$$

$$\Theta_b = C_1 + C_2 \quad \Theta_c = C_1 e^{mL} + C_2 e^{-mL}$$

it follows that

$$C_1 = \frac{\Theta_b e^{-mL} - \Theta_c}{e^{-mL} - e^{mL}} \quad C_2 = \frac{\Theta_c - \Theta_b e^{mL}}{e^{-mL} - e^{mL}}$$

$$\Theta(x) = \frac{(\Theta_b e^{-mL} - \Theta_c) e^{mx} + (\Theta_c - \Theta_b e^{mL}) e^{-mx}}{e^{-mL} - e^{mL}}$$

<

COMMENTS: If \dot{q} is large and h is small, temperatures within the lead may readily exceed the prescribed boundary temperatures.

PROBLEM 3.115

KNOWN: Disk-shaped electronic device (D , L_d , k_d) dissipates electrical power (P_e) at one of its surfaces. Device is bonded to a cooled base (T_o) using a thermal pad (L_p , k_p). Long fin (D , k_f) is bonded to the heat-generating surface using an identical thermal pad. Fin is cooled by convection (T_∞ , h).

FIND: (a) Construct a thermal circuit of the system, (b) Derive an expression for the temperature of the heat-generating device, T_d , in terms of circuit thermal resistance, T_o and T_∞ ; write expressions for the thermal resistances; and (c) Calculate T_d for the prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction through thermal pads and device; no losses from lateral surfaces; (3) Fin is infinitely long, (4) Negligible contact resistance between components of the system, (5) Constant properties, (6) Negligible radiation heat transfer.

ANALYSIS: (a) The thermal circuit is shown below with thermal resistances associated with conduction (pads, R_p ; device, R_d) and for the long fin, R_f .

(b) To obtain an expression for T_d , perform an energy balance about the d-node

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = q_a + q_b + P_e = 0 \quad (1)$$

Using the conduction rate equation with the circuit

$$q_a = \frac{T_o - T_d}{R_p + R_d} \quad q_b = \frac{T_\infty - T_d}{R_p + R_f} \quad (2,3)$$

Combine with Eq. (1), and solve for T_d ,

$$T_d = \frac{P_e + T_o / (R_p + R_d) + T_\infty / (R_p + R_f)}{1 / (R_p + R_d) + 1 / (R_p + R_f)} \quad (4)$$

where the thermal resistances with $P = \pi D$ and $A_c = \pi D^2/4$ are

$$R_p = L_p / k_p A_c \quad R_d = L_d / k_d A_c \quad R_f = (h P k_f A_c)^{-1/2} \quad (5,6,7)$$

(c) Substituting numerical values with the foregoing relations, find

$$R_p = 1.061\text{ K/W} \quad R_d = 4.244\text{ K/W} \quad R_f = 5.712\text{ K/W}$$

and the device temperature as

$$T_d = 62.4^\circ\text{C} \quad <$$

COMMENTS: What fraction of the power dissipated in the device is removed by the fin? Answer:

$$q_b / P_e = 47\%.$$

PROBLEM 3.116

KNOWN: Dimensions and thermal conductivity of a gas turbine blade. Temperature and convection coefficient of gas stream. Temperature of blade base and maximum allowable blade temperature.

FIND: (a) Whether blade operating conditions are acceptable, (b) Heat transfer to blade coolant.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction in blade, (2) Constant k , (3) Adiabatic blade tip, (4) Negligible radiation.

ANALYSIS: Conditions in the blade are determined by Case B of Table 3.4.

(a) With the maximum temperature existing at $x = L$, Eq. 3.75 yields

$$\frac{T(L) - T_\infty}{T_b - T_\infty} = \frac{1}{\cosh mL}$$

$$m = (hP/kA_c)^{1/2} = \left(250 \text{ W/m}^2 \cdot \text{K} \times 0.11 \text{ m} / 20 \text{ W/m} \cdot \text{K} \times 6 \times 10^{-4} \text{ m}^2\right)^{1/2}$$

$$m = 47.87 \text{ m}^{-1} \quad \text{and} \quad mL = 47.87 \text{ m}^{-1} \times 0.05 \text{ m} = 2.39$$

From Table B.1, $\cosh mL = 5.51$. Hence,

$$T(L) = 1200^\circ \text{C} + (300 - 1200)^\circ \text{C} / 5.51 = 1037^\circ \text{C}$$

<

and the operating conditions are acceptable.

$$(b) \text{ With } M = (hPkA_c)^{1/2} \Theta_b = \left(250 \text{ W/m}^2 \cdot \text{K} \times 0.11 \text{ m} \times 20 \text{ W/m} \cdot \text{K} \times 6 \times 10^{-4} \text{ m}^2\right)^{1/2} (-900^\circ \text{C}) = -517 \text{ W},$$

Eq. 3.76 and Table B.1 yield

$$q_f = M \tanh mL = -517 \text{ W} (0.983) = -508 \text{ W}$$

$$\text{Hence, } q_b = -q_f = 508 \text{ W}$$

<

COMMENTS: Radiation losses from the blade surface and convection from the tip will contribute to reducing the blade temperatures.

PROBLEM 3.117

KNOWN: Dimensions of disc/shaft assembly. Applied angular velocity, force, and torque. Thermal conductivity and inner temperature of disc.

FIND: (a) Expression for the friction coefficient μ , (b) Radial temperature distribution in disc, (c) Value of μ for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant k , (4) Uniform disc contact pressure p , (5) All frictional heat dissipation is transferred to shaft from base of disc.

ANALYSIS: (a) The normal force acting on a differential ring extending from r to $r+dr$ on the contact surface of the disc may be expressed as $dF_n = p2\pi r dr$. Hence, the tangential force is $dF_t = \mu p 2\pi r dr$, in which case the torque may be expressed as

$$d\tau = 2\pi\mu p r^2 dr$$

For the entire disc, it follows that

$$\tau = 2\pi\mu p \int_0^{r_2} r^2 dr = \frac{2\pi}{3} \mu p r_2^3$$

where $p = F/\pi r_2^2$. Hence,

$$\mu = \frac{3}{2} \frac{\tau}{F r_2}$$

(b) Performing an energy balance on a differential control volume in the disc, it follows that

$$q_{\text{cond},r} + dq_{\text{fric}} - q_{\text{cond},r+dr} = 0$$

With $dq_{\text{fric}} = \omega d\tau = 2\mu F \omega \left(r^2/r_2^2 \right) dr$, $q_{\text{cond},r+dr} = q_{\text{cond},r} + (dq_{\text{cond},r}/dr) dr$, and

$q_{\text{cond},r} = -k(2\pi r t) dT/dr$, it follows that

$$2\mu F \omega \left(r^2/r_2^2 \right) dr + 2\pi k t \frac{d(rdT/dr)}{dr} dr = 0$$

or

$$\frac{d(rdT/dr)}{dr} = -\frac{\mu F \omega}{\pi k t r_2^2} r^2$$

Integrating twice,

Continued...

PROBLEM 3.117 (Cont.)

$$\frac{dT}{dr} = -\frac{\mu F \omega}{3\pi k r_2^2} r^2 + \frac{C_1}{r}$$

$$T = -\frac{\mu F \omega}{9\pi k r_2^2} r^3 + C_1 \ln r + C_2$$

Since the disc is well insulated at $r = r_2$, $dT/dr|_{r_2} = 0$ and

$$C_1 = \frac{\mu F \omega r_2}{3\pi k t}$$

With $T(r_1) = T_1$, it also follows that

$$C_2 = T_1 + \frac{\mu F \omega}{9\pi k r_2^2} r_1^3 - C_1 \ln r_1$$

Hence,

$$T(r) = T_1 - \frac{\mu F \omega}{9\pi k r_2^2} (r^3 - r_1^3) + \frac{\mu F \omega r_2}{3\pi k t} \ln \frac{r}{r_1} \quad <$$

(c) For the prescribed conditions,

$$\mu = \frac{3}{2} \frac{8 \text{ N} \cdot \text{m}}{200 \text{ N} (0.18 \text{ m})} = 0.333 \quad <$$

Since the maximum temperature occurs at $r = r_2$,

$$T_{\max} = T(r_2) = T_1 - \frac{\mu F \omega r_2}{9\pi k t} \left[1 - \left(\frac{r_1}{r_2} \right)^3 \right] + \frac{\mu F \omega r_2}{3\pi k t} \ln \left(\frac{r_2}{r_1} \right)$$

With $(\mu F \omega r_2 / 3\pi k t) = (0.333 \times 200 \text{ N} \times 40 \text{ rad/s} \times 0.18 \text{ m} / 3\pi \times 15 \text{ W/m} \cdot \text{K} \times 0.012 \text{ m}) = 282.7^\circ \text{C}$,

$$T_{\max} = 80^\circ \text{C} - \frac{282.7^\circ \text{C}}{3} \left[1 - \left(\frac{0.02}{0.18} \right)^3 \right] + 282.7^\circ \text{C} \ln \left(\frac{0.18}{0.02} \right)$$

$$T_{\max} = 80^\circ \text{C} - 94.1^\circ \text{C} + 621.1^\circ \text{C} = 607^\circ \text{C} \quad <$$

COMMENTS: The maximum temperature is excessive, and the disks should be actively cooled (by convection) at their outer surfaces.

PROBLEM 3.118

KNOWN: Extended surface of rectangular cross-section with heat flow in the longitudinal direction.

FIND: Determine the conditions for which the transverse (y -direction) temperature difference is negligible compared to the temperature difference between the surface and the environment, such that the 1-D analysis of Section 3.6.1 is valid by finding: (a) An expression for the conduction heat flux at the surface, $q_y''(t)$, in terms of T_s and T_o , assuming the transverse temperature distribution is parabolic; (b) An expression for the convection heat flux at the surface for the x -location; equate the two expressions, and identify the parameter that determines the ratio $(T_o - T_s)/(T_s - T_\infty)$; and (c) Developing a criterion for the validity of the 1-D assumption used to model an extended surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform convection coefficient and (3) Constant properties.

ANALYSIS: (a) Referring to the schematics above, the conduction heat flux at the surface $y = t$ at any x -location follows from Fourier's law using the parabolic transverse temperature distribution.

$$q_y''(t) = -k \frac{\partial T}{\partial y} \bigg|_{y=t} = -k \left[(T_s(x) - T_o(x)) \frac{2y}{t^2} \right]_{y=t} = -\frac{2k}{t} [T_s(x) - T_o(x)] \quad (1)$$

(b) The convection heat flux at the surface of any x -location follows from the rate equation

$$q_{cv}'' = h [T_s(x) - T_\infty] \quad (2)$$

Performing a surface energy balance as represented schematically above, equating Eqs. (1) and (2) provides

$$\begin{aligned} q_y''(t) &= q_{cv}'' \\ -\frac{2k}{t} [T_s(x) - T_o(x)] &= h [T_s(x) - T_\infty] \\ \frac{T_s(x) - T_o(x)}{T_s(x) - T_\infty} &= -0.5 \frac{ht}{k} = -0.5 \text{ Bi} \end{aligned} \quad (3)$$

where $\text{Bi} = ht/k$, the Biot number, represents the ratio of the conduction to the convection thermal resistances,

$$\text{Bi} = \frac{R_{cd}''}{R_{cv}''} = \frac{t/k}{1/h} \quad (4)$$

(c) The transverse temperature difference $(T_s - T_o)$ will be negligible compared to the temperature difference between the surface and the environment $(T_s - T_\infty)$ when $\text{Bi} \ll 1$, say, 0.1, an order of magnitude smaller. This is the criterion to validate the one-dimensional assumption used to model extended surfaces.

COMMENTS: The coefficient 0.5 in Eq. (3) is a consequence of the parabolic distribution assumption. This distribution represents the simplest polynomial expression that could approximate the real distribution.

PROBLEM 3.119

KNOWN: Long, aluminum cylinder acts as an extended surface.

FIND: (a) Increase in heat transfer if diameter is tripled and (b) Increase in heat transfer if copper is used in place of aluminum.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Uniform convection coefficient, (5) Rod is infinitely long.

PROPERTIES: Table A-1, Aluminum (pure): $k = 240 \text{ W/m}\cdot\text{K}$; Table A-1, Copper (pure): $k = 400 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) For an infinitely long fin, the fin heat rate from Table 3.4 is

$$q_f = M = (hPkA_c)^{1/2} \theta_b$$

$$q_f = \left(h \pi D k \pi D^2 / 4 \right)^{1/2} \theta_b = \frac{\pi}{2} (hk)^{1/2} D^{3/2} \theta_b.$$

where $P = \pi D$ and $A_c = \pi D^2 / 4$ for the circular cross-section. Note that $q_f \propto D^{3/2}$. Hence, if the diameter is tripled,

$$\frac{q_f(3D)}{q_f(D)} = 3^{3/2} = 5.2$$

and there is a 420% increase in heat transfer. <

(b) In changing from aluminum to copper, since $q_f \propto k^{1/2}$, it follows that

$$\frac{q_f(\text{Cu})}{q_f(\text{Al})} = \left[\frac{k_{\text{Cu}}}{k_{\text{Al}}} \right]^{1/2} = \left[\frac{400}{240} \right]^{1/2} = 1.29$$

and there is a 29% increase in the heat transfer rate. <

COMMENTS: (1) Because fin effectiveness is enhanced by maximizing $P/A_c = 4/D$, the use of a larger number of small diameter fins is preferred to a single large diameter fin.

(2) From the standpoint of cost, weight and machinability, aluminum is preferred over copper.

PROBLEM 3.120

KNOWN: Length, diameter, base temperature and environmental conditions associated with a brass rod.

FIND: Temperature at specified distances along the rod.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient h .

PROPERTIES: Table A-1, Brass ($\bar{T} = 110^\circ\text{C}$): $k = 133 \text{ W/m}\cdot\text{K}$.

ANALYSIS: Evaluate first the fin parameter

$$m = \left[\frac{hP}{kA_c} \right]^{1/2} = \left[\frac{h\pi D}{k\pi D^2/4} \right]^{1/2} = \left[\frac{4h}{kD} \right]^{1/2} = \left[\frac{4 \times 30 \text{ W/m}^2 \cdot \text{K}}{133 \text{ W/m}\cdot\text{K} \times 0.005 \text{ m}} \right]^{1/2}$$

$$m = 13.43 \text{ m}^{-1}.$$

Hence, $mL = (13.43) \times 0.1 = 1.34$ and from the results of Example 3.9, it is advisable not to make the infinite rod approximation. Thus from Table 3.4, the temperature distribution has the form

$$\theta = \frac{\cosh m(L-x) + (h/mk) \sinh m(L-x)}{\cosh mL + (h/mk) \sinh mL} \theta_b$$

Evaluating the hyperbolic functions, $\cosh mL = 2.04$ and $\sinh mL = 1.78$, and the parameter

$$\frac{h}{mk} = \frac{30 \text{ W/m}^2 \cdot \text{K}}{13.43 \text{ m}^{-1} (133 \text{ W/m}\cdot\text{K})} = 0.0168,$$

with $\theta_b = 180^\circ\text{C}$ the temperature distribution has the form

$$\theta = \frac{\cosh m(L-x) + 0.0168 \sinh m(L-x)}{2.07} (180^\circ\text{C}).$$

The temperatures at the prescribed locations are tabulated below.

$x(\text{m})$	$\cosh m(L-x)$	$\sinh m(L-x)$	θ	$T(^\circ\text{C})$	
$x_1 = 0.025$	1.55	1.19	136.5	156.5	<
$x_2 = 0.05$	1.24	0.725	108.9	128.9	<
$L = 0.10$	1.00	0.00	87.0	107.0	<

COMMENTS: If the rod were approximated as infinitely long: $T(x_1) = 148.7^\circ\text{C}$, $T(x_2) = 112.0^\circ\text{C}$, and $T(L) = 67.0^\circ\text{C}$. The assumption would therefore result in significant underestimates of the rod temperature.

PROBLEM 3.121

KNOWN: Thickness, length, thermal conductivity, and base temperature of a rectangular fin. Fluid temperature and convection coefficient.

FIND: (a) Heat rate per unit width, efficiency, effectiveness, thermal resistance, and tip temperature for different tip conditions, (b) Effect of convection coefficient and thermal conductivity on the heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along fin, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient, (6) Fin width is much longer than thickness ($w \gg t$).

ANALYSIS: (a) The fin heat transfer rate for Cases A, B and D are given by Eqs. (3.72), (3.76) and (3.80), where $M \approx (2 h w^2 t k)^{1/2} (T_b - T_\infty) = (2 \times 100 \text{ W/m}^2 \cdot \text{K} \times 0.001 \text{ m} \times 180 \text{ W/m} \cdot \text{K})^{1/2} (75^\circ\text{C}) w = 450 \text{ W}$, $m \approx (2 h / k t)^{1/2} = (200 \text{ W/m}^2 \cdot \text{K} / 180 \text{ W/m} \cdot \text{K} \times 0.001 \text{ m})^{1/2} = 33.3 \text{ m}^{-1}$, $mL \approx 33.3 \text{ m}^{-1} \times 0.010 \text{ m} = 0.333$, and $(h/mk) \approx (100 \text{ W/m}^2 \cdot \text{K} / 33.3 \text{ m}^{-1} \times 180 \text{ W/m} \cdot \text{K}) = 0.0167$. From Table B-1, it follows that $\sinh mL \approx 0.340$, $\cosh mL \approx 1.057$, and $\tanh mL \approx 0.321$. From knowledge of q_f , Eqs. (3.86), (3.81) and (3.83) yield

$$\eta_f \approx \frac{q'_f}{h(2L+t)\theta_b}, \quad \varepsilon_f \approx \frac{q'_f}{ht\theta_b}, \quad R'_{t,f} = \frac{\theta_b}{q'_f}$$

Case A: From Eq. (3.72), (3.86), (3.81), (3.83) and (3.70),

$$q'_f = \frac{M \sinh mL + (h/mk) \cosh mL}{w \cosh mL + (h/mk) \sinh mL} = 450 \text{ W/m} \frac{0.340 + 0.0167 \times 1.057}{1.057 + 0.0167 \times 0.340} = 151 \text{ W/m} \quad <$$

$$\eta_f = \frac{151 \text{ W/m}}{100 \text{ W/m}^2 \cdot \text{K} (0.021 \text{ m}) 75^\circ\text{C}} = 0.96 \quad <$$

$$\varepsilon_f = \frac{151 \text{ W/m}}{100 \text{ W/m}^2 \cdot \text{K} (0.001 \text{ m}) 75^\circ\text{C}} = 20.2, \quad R'_{t,f} = \frac{75^\circ\text{C}}{151 \text{ W/m}} = 0.50 \text{ m} \cdot \text{K/W} \quad <$$

$$T(L) = T_\infty + \frac{\theta_b}{\cosh mL + (h/mk) \sinh mL} = 25^\circ\text{C} + \frac{75^\circ\text{C}}{1.057 + (0.0167) 0.340} = 95.6^\circ\text{C} \quad <$$

Case B: From Eqs. (3.76), (3.86), (3.81), (3.83) and (3.75)

$$q'_f = \frac{M}{w} \tanh mL = 450 \text{ W/m} (0.321) = 144 \text{ W/m} \quad <$$

$$\eta_f = 0.92, \quad \varepsilon_f = 19.3, \quad R'_{t,f} = 0.52 \text{ m} \cdot \text{K/W} \quad <$$

$$T(L) = T_\infty + \frac{\theta_b}{\cosh mL} = 25^\circ\text{C} + \frac{75^\circ\text{C}}{1.057} = 96.0^\circ\text{C} \quad <$$

Continued

PROBLEM 3.121 (Cont.)

Case D ($L \rightarrow \infty$): From Eqs. (3.80), (3.86), (3.81), (3.83) and (3.79)

$$q'_f = \frac{M}{w} = 450 \text{ W/m}$$

$$\eta_f = 0, \varepsilon_f = 60.0, R'_{t,f} = 0.167 \text{ m} \cdot \text{K} / \text{W}, T(L) = T_\infty = 25^\circ\text{C}$$

(b) The effect of h on the heat rate is shown below for the aluminum and stainless steel fins.

For both materials, there is little difference between the Case A and B results over the entire range of h . The difference (percentage) increases with decreasing h and increasing k , but even for the worst case condition ($h = 10 \text{ W/m}^2 \cdot \text{K}$, $k = 180 \text{ W/m.K}$), the heat rate for Case A (15.7 W/m) is only slightly larger than that for Case B (14.9 W/m). For aluminum, the heat rate is significantly over-predicted by the infinite fin approximation over the entire range of h . For stainless steel, it is over-predicted for small values of h , but results for all three cases are within 1% for $h > 500 \text{ W/m}^2 \cdot \text{K}$.

COMMENTS: From the results of Part (a), we see there is a slight reduction in performance (smaller values of q'_f , η_f and ε_f , as well as a larger value of $R'_{t,f}$) associated with insulating the tip.

Although $\eta_f = 0$ for the infinite fin, q'_f and ε_f are substantially larger than results for $L = 10 \text{ mm}$, indicating that performance may be significantly improved by increasing L .

PROBLEM 3.122

KNOWN: Thickness, length, thermal conductivity, and base temperature of a rectangular fin. Fluid temperature and convection coefficient.

FIND: (a) Heat rate per unit width, efficiency, effectiveness, thermal resistance, and tip temperature for different tip conditions, (b) Effect of fin length and thermal conductivity on the heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along fin, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient, (6) Fin width is much longer than thickness ($w \gg t$).

ANALYSIS: (a) The fin heat transfer rate for Cases A, B and D are given by Eqs. (3.72), (3.76) and (3.80), where $M \approx (2 h w^2 k)^{1/2} (T_b - T_\infty) = (2 \times 100 \text{ W/m}^2 \cdot \text{K} \times 0.001 \text{ m} \times 180 \text{ W/m} \cdot \text{K})^{1/2} (75^\circ \text{C}) w = 450 \text{ W}$, $m \approx (2h/kt)^{1/2} = (200 \text{ W/m}^2 \cdot \text{K} / 180 \text{ W/m} \cdot \text{K} \times 0.001 \text{ m})^{1/2} = 33.3 \text{ m}^{-1}$, $mL \approx 33.3 \text{ m}^{-1} \times 0.010 \text{ m} = 0.333$, and $(h/mk) \approx (100 \text{ W/m}^2 \cdot \text{K} / 33.3 \text{ m}^{-1} \times 180 \text{ W/m} \cdot \text{K}) = 0.0167$. From Table B-1, it follows that $\sinh mL \approx 0.340$, $\cosh mL \approx 1.057$, and $\tanh mL \approx 0.321$. From knowledge of q_f , Eqs. (3.86), (3.81) and (3.83) yield

$$\eta_f \approx \frac{q_f'}{h(2L+t)\theta_b}, \quad \varepsilon_f \approx \frac{q_f'}{ht\theta_b}, \quad R'_{t,f} = \frac{\theta_b}{q_f'}$$

Case A: From Eq. (3.72), (3.86), (3.81), (3.83) and (3.70),

$$q_f' = \frac{M \sinh mL + (h/mk) \cosh mL}{w \cosh mL + (h/mk) \sinh mL} = 450 \text{ W/m} \frac{0.340 + 0.0167 \times 1.057}{1.057 + 0.0167 \times 0.340} = 151 \text{ W/m} \quad <$$

$$\eta_f = \frac{151 \text{ W/m}}{100 \text{ W/m}^2 \cdot \text{K} (0.021 \text{ m}) 75^\circ \text{C}} = 0.96 \quad <$$

$$\varepsilon_f = \frac{151 \text{ W/m}}{100 \text{ W/m}^2 \cdot \text{K} (0.001 \text{ m}) 75^\circ \text{C}} = 20.1, \quad R'_{t,f} = \frac{75^\circ \text{C}}{151 \text{ W/m}} = 0.50 \text{ m} \cdot \text{K/W} \quad <$$

$$T(L) = T_\infty + \frac{\theta_b}{\cosh mL + (h/mk) \sinh mL} = 25^\circ \text{C} + \frac{75^\circ \text{C}}{1.057 + (0.0167) 0.340} = 95.6^\circ \text{C} \quad <$$

Case B: From Eqs. (3.76), (3.86), (3.81), (3.83) and (3.75)

$$q_f' = \frac{M}{w} \tanh mL = 450 \text{ W/m} (0.321) = 144 \text{ W/m} \quad <$$

$$\eta_f = 0.92, \quad \varepsilon_f = 19.2, \quad R'_{t,f} = 0.52 \text{ m} \cdot \text{K/W} \quad <$$

$$T(L) = T_\infty + \frac{\theta_b}{\cosh mL} = 25^\circ \text{C} + \frac{75^\circ \text{C}}{1.057} = 96.0^\circ \text{C} \quad <$$

Continued ...

PROBLEM 3.122 (Cont.)

Case D ($L \rightarrow \infty$): From Eqs. (3.80), (3.86), (3.81), (3.83) and (3.79)

$$q_f' = \frac{M}{w} = 450 \text{ W/m}$$

$$\eta_f = 0, \varepsilon_f = 60.0, R_{t,f}' = 0.167 \text{ m} \cdot \text{K/W}, T(L) = T_\infty = 25^\circ\text{C}$$

(b) The effect of L on the heat rate is shown below for the aluminum and stainless steel fins.

For both materials, differences between the Case A and B results diminish with increasing L and are within 1% of each other at $L \approx 27 \text{ mm}$ and $L \approx 13 \text{ mm}$ for the aluminum and steel, respectively. At $L = 3 \text{ mm}$, results differ by 14% and 13% for the aluminum and steel, respectively. The Case A and B results approach those of the infinite fin approximation more quickly for stainless steel due to the larger temperature gradients, $|dT/dx|$, for the smaller value of k .

COMMENTS: From the results of Part (a), we see there is a slight reduction in performance (smaller values of q_f' , η_f and ε_f , as well as a larger value of $R_{t,f}'$) associated with insulating the tip.

Although $\eta_f = 0$ for the infinite fin, q_f' and ε_f are substantially larger than results for $L = 10 \text{ mm}$, indicating that performance may be significantly improved by increasing L .

PROBLEM 3.123

KNOWN: Length, thickness and temperature of straight fins of rectangular, triangular and parabolic profiles. Ambient air temperature and convection coefficient.

FIND: Heat rate per unit width, efficiency and volume of each fin.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient.

ANALYSIS: For each fin,

$$q'_f = q'_{\max} = \eta_f h A'_f (T_b - T_\infty), \quad V' = A_p L$$

where η_f depends on the value of $m = (2h/kt)^{1/2} = (100 \text{ W/m}^2 \cdot \text{K} / 185 \text{ W/m} \cdot \text{K} \times 0.003 \text{ m})^{1/2} = 13.4 \text{ m}^{-1}$ and the product $mL = 13.4 \text{ m}^{-1} \times 0.015 \text{ m} = 0.201$ or $mL_c = 0.222$. Expressions for η_f , A'_f and A_p are obtained from Table 3-5.

Rectangular Fin:

$$\eta_f = \frac{\tanh mL_c}{mL_c} = \frac{0.218}{0.222} = 0.982, \quad A'_f = 2L_c = 0.033 \text{ m} \quad <$$

$$q' = 0.982 (50 \text{ W/m}^2 \cdot \text{K}) (0.033 \text{ m}) (80^\circ\text{C}) = 129.6 \text{ W/m}, \quad V' = tL = 4.5 \times 10^{-5} \text{ m}^2 \quad <$$

Triangular Fin:

$$\eta_f = \frac{1 - I_0(2mL)}{mL I_0(2mL)} = \frac{0.205}{(0.201)1.042} = 0.978, \quad A'_f = 2 \left[L^2 + (t/2)^2 \right]^{1/2} = 0.030 \text{ m} \quad <$$

$$q' = 0.978 (50 \text{ W/m}^2 \cdot \text{K}) (0.030 \text{ m}) (80^\circ\text{C}) = 117.3 \text{ W/m}, \quad V' = (t/2)L = 2.25 \times 10^{-5} \text{ m}^2 \quad <$$

Parabolic Fin:

$$\eta_f = \frac{2}{\left[4(mL)^2 + 1 \right]^{1/2} + 1} = 0.963, \quad A'_f = \left[C_1 L + \left(L^2 + t \right) \ln(t/L + C_1) \right] = 0.030 \text{ m} \quad <$$

$$q' = 0.963 (50 \text{ W/m}^2 \cdot \text{K}) (0.030 \text{ m}) (80^\circ\text{C}) = 115.6 \text{ W/m}, \quad V' = (t/3)L = 1.5 \times 10^{-5} \text{ m}^2 \quad <$$

COMMENTS: Although the heat rate is slightly larger (~10%) for the rectangular fin than for the triangular or parabolic fins, the heat rate per unit volume (or mass) is larger and largest for the triangular and parabolic fins, respectively.

PROBLEM 3.124

KNOWN: Melting point of solder used to join two long copper rods.

FIND: Minimum power needed to solder the rods.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction along the rods, (3) Constant properties, (4) No internal heat generation, (5) Negligible radiation exchange with surroundings, (6) Uniform h , and (7) Infinitely long rods.

PROPERTIES: Table A-1: Copper $\bar{T} = (650 + 25)^\circ\text{C} \approx 600\text{K}$; $k = 379\text{ W/m}\cdot\text{K}$.

ANALYSIS: The junction must be maintained at 650°C while energy is transferred by conduction from the junction (along both rods). The minimum power is twice the fin heat rate for an infinitely long fin.

$$\dot{q}_{\min} = 2\dot{q}_f = 2(hPkA_c)^{1/2}(T_b - T_\infty).$$

Substituting numerical values,

$$\dot{q}_{\min} = 2 \left[10 \frac{\text{W}}{\text{m}^2\cdot\text{K}} (\pi \times 0.01\text{ m}) \left[379 \frac{\text{W}}{\text{m}\cdot\text{K}} \right] \frac{\pi}{4} (0.01\text{ m})^2 \right]^{1/2} (650 - 25)^\circ\text{C}.$$

Therefore,

$$\dot{q}_{\min} = 120.9\text{ W}.$$

COMMENTS: Radiation losses from the rods may be significant, particularly near the junction, thereby requiring a larger power input to maintain the junction at 650°C .

<

PROBLEM 3.125

KNOWN: Dimensions and end temperatures of pin fins.

FIND: (a) Heat transfer by convection from a single fin and (b) Total heat transfer from a 1 m^2 surface with fins mounted on 4mm centers.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along rod, (3) Constant properties, (4) No internal heat generation, (5) Negligible radiation.

PROPERTIES: Table A-1, Copper, pure (323K): $k \approx 400 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) By applying conservation of energy to the fin, it follows that

$$q_{\text{conv}} = q_{\text{cond},i} - q_{\text{cond},o}$$

where the conduction rates may be evaluated from knowledge of the temperature distribution. The general solution for the temperature distribution is

$$\theta(x) = C_1 e^{mx} + C_2 e^{-mx} \quad \theta \equiv T - T_{\infty}.$$

The boundary conditions are $\theta(0) \equiv \theta_o = 100^\circ\text{C}$ and $\theta(L) = 0$. Hence

$$\theta_o = C_1 + C_2$$

$$0 = C_1 e^{mL} + C_2 e^{-mL}$$

Therefore, $C_2 = C_1 e^{2mL}$

$$C_1 = \frac{\theta_o}{1 - e^{2mL}}, \quad C_2 = -\frac{\theta_o e^{2mL}}{1 - e^{2mL}}$$

and the temperature distribution has the form

$$\theta = \frac{\theta_o}{1 - e^{2mL}} \left[e^{mx} - e^{2mL - mx} \right].$$

The conduction heat rate can be evaluated by Fourier's law,

$$q_{\text{cond}} = -kA_c \frac{d\theta}{dx} = -\frac{kA_c \theta_o}{1 - e^{2mL}} m \left[e^{mx} + e^{2mL - mx} \right]$$

or, with $m = (hP/kA_c)^{1/2}$,

$$q_{\text{cond}} = -\frac{\theta_o (hPkA_c)^{1/2}}{1 - e^{2mL}} \left[e^{mx} + e^{2mL - mx} \right].$$

Continued

PROBLEM 3.125 (Cont.)

Hence at $x = 0$,

$$q_{\text{cond},i} = -\frac{\theta_o (hPkA_c)^{1/2}}{1 - e^{2mL}} (1 + e^{2mL})$$

at $x = L$

$$q_{\text{cond},o} = -\frac{\theta_o (hPkA_c)^{1/2}}{1 - e^{2mL}} (2e^{mL})$$

Evaluating the fin parameters:

$$m = \left[\frac{hP}{kA_c} \right]^{1/2} = \left[\frac{4h}{kD} \right]^{1/2} = \left[\frac{4 \times 100 \text{ W/m}^2 \cdot \text{K}}{400 \text{ W/m} \cdot \text{K} \times 0.001 \text{ m}} \right]^{1/2} = 31.62 \text{ m}^{-1}$$

$$(hPkA_c)^{1/2} = \left[\frac{\pi^2}{4} D^3 h k \right]^{1/2} = \left[\frac{\pi^2}{4} \times (0.001 \text{ m})^3 \times 100 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times 400 \frac{\text{W}}{\text{m} \cdot \text{K}} \right]^{1/2} = 9.93 \times 10^{-3} \frac{\text{W}}{\text{K}}$$

$$mL = 31.62 \text{ m}^{-1} \times 0.025 \text{ m} = 0.791, \quad e^{mL} = 2.204, \quad e^{2mL} = 4.865$$

The conduction heat rates are

$$q_{\text{cond},i} = \frac{-100 \text{ K} (9.93 \times 10^{-3} \text{ W/K})}{-3.865} \times 5.865 = 1.507 \text{ W}$$

$$q_{\text{cond},o} = \frac{-100 \text{ K} (9.93 \times 10^{-3} \text{ W/K})}{-3.865} \times 4.408 = 1.133 \text{ W}$$

and from the conservation relation,

$$q_{\text{conv}} = 1.507 \text{ W} - 1.133 \text{ W} = 0.374 \text{ W}. \quad <$$

(b) The total heat transfer rate is the heat transfer from $N = 250 \times 250 = 62,500$ rods and the heat transfer from the remaining (bare) surface ($A = 1 \text{ m}^2 - NA_c$). Hence,

$$q = N q_{\text{cond},i} + hA\theta_o = 62,500 (1.507 \text{ W}) + 100 \text{ W/m}^2 \cdot \text{K} (0.951 \text{ m}^2) 100 \text{ K}$$

$$q = 9.42 \times 10^4 \text{ W} + 0.95 \times 10^4 \text{ W} = 1.037 \times 10^5 \text{ W}.$$

COMMENTS: (1) The fins, which cover only 5% of the surface area, provide for more than 90% of the heat transfer from the surface.

(2) The fin effectiveness, $\varepsilon \equiv q_{\text{cond},i} / hA_c\theta_o$, is $\varepsilon = 192$, and the fin efficiency,

$\eta \equiv (q_{\text{conv}} / h\pi DL\theta_o)$, is $\eta = 0.48$.

(3) The temperature distribution, $\theta(x)/\theta_o$, and the conduction term, $q_{\text{cond},i}$, could have been obtained directly from Eqs. 3.77 and 3.78, respectively.

(4) Heat transfer by convection from a single fin could also have been obtained from Eq. 3.73.

PROBLEM 3.126

KNOWN: Dimensions of a nanospring, dependence of pitch upon temperature.

FIND: Actuation distance of the spring in response to heating of its end, accuracy to which the actuation length can be controlled.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Steady-state conditions, (3) One-dimensional heat transfer, (4) Adiabatic tip, (5) Negligible radiation heat transfer, (6) Negligible impact of nanoscale heat transfer effects.

PROPERTIES: Table A.2, silicon carbide (300 K): $k = 490 \text{ W/m}\cdot\text{K}$.

ANALYSIS: When the nanospring is at $T_i = 25^\circ\text{C}$, the spring length is

$$L_i = \frac{s}{2\pi} \frac{L_c}{\sqrt{r^2 + (s/2\pi)^2}} = \frac{25 \times 10^{-9} \text{ m}}{2\pi} \times \frac{425 \times 10^{-9} \text{ m}}{\sqrt{(30 \times 10^{-9} \text{ m})^2 + \left(25 \times 10^{-9} \text{ m} / 2\pi\right)^2}}$$

$$= 55.9 \times 10^{-9} \text{ m} = 55.9 \text{ nm}$$

Since the average spring pitch varies linearly with the average temperature, the average pitch of the heated spring is

$$\bar{s} = s_i + \frac{ds}{dT} (\bar{T} - T_i) \quad (1)$$

The average excess temperature is

$$\bar{\theta} = \bar{T} - T_\infty = \frac{1}{L_c} \int_{x=0}^{L_c} \theta(x) dx \quad \text{where, from Eq. 3.75,}$$

Continued...

PROBLEM 3.126 (Cont.)

$$\bar{\theta} = \frac{\theta_b}{L_c} \int_{x=0}^{L_c} \frac{\cosh m(L-x)}{\cosh mL} dx = - \frac{\theta_b}{mL_c (\cosh mL_c)} \sinh m(L_c - x) \Big|_0^{L_c}$$

$$\bar{\theta} = \frac{\theta_b}{mL_c (\cosh mL_c)} \times (0 - \sinh mL_c) = \frac{\theta_b}{mL_c} \tanh (mL_c)$$

For a particular spring,

$$mL_c = \left(\frac{hP}{kA_c} \right)^{1/2} L_c = \left(\frac{4h}{kD} \right)^{1/2} L_c = \left(\frac{4 \times 10^6 \text{ W/m}^2 \cdot \text{K}}{490 \text{ W/m} \cdot \text{K} \times 15 \times 10^{-9} \text{ m}} \right)^{1/2} \times 425 \times 10^{-9} \text{ m} = 0.314$$

Therefore $\bar{\theta} = \frac{(50 - 25)^\circ\text{C}}{0.314} \tanh (0.314) = 24.2^\circ\text{C}$

and $\bar{T} = \bar{\theta} + T_\infty = 24.2^\circ\text{C} + 25^\circ\text{C} = 49.2^\circ\text{C}$

From Eq. (1),

$$\bar{s} = 25 \times 10^{-9} \text{ m} + 0.1 \times 10^{-9} \text{ m/K} \times (49.2 - 25)^\circ\text{C} = 27.4 \times 10^{-9} \text{ m}$$

Therefore,

$$L_2 = \frac{27.4 \times 10^{-9} \text{ m}}{2\pi} \times \frac{425 \times 10^{-9} \text{ m}}{\sqrt{(30 \times 10^{-9} \text{ m})^2 + (27.4 \times 10^{-9} \text{ m} / 2\pi)^2}} = 61.1 \times 10^{-9} \text{ m} = 61.1 \text{ nm}$$

and the actuation length is

$$\Delta L = L_2 - L_1 = 61.1 \text{ nm} - 55.9 \text{ nm} = 5.2 \text{ nm} \quad <$$

If the base temperature can be controlled to within 1 degree Celsius, the resolution of the

actuation length is: $R = \Delta L \times \frac{1 \text{ degree C}}{25 \text{ degree C}} = 0.2 \text{ nm} \quad <$

COMMENTS: (1) The actuation distance and its resolution are extremely small. (2) Application of other tip conditions will lead to different predictions of the actuation distance.

PROBLEM 3.127

KNOWN: Positions of equal temperature on two long rods of the same diameter, but different thermal conductivity, which are exposed to the same base temperature and ambient air conditions.

FIND: Thermal conductivity of rod B, k_B .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Rods are infinitely long fins of uniform cross-sectional area, (3) Uniform heat transfer coefficient, (4) Constant properties.

ANALYSIS: The temperature distribution for the infinite fin has the form

$$\frac{\theta}{\theta_b} = \frac{T(x) - T_\infty}{T_o - T_\infty} = e^{-mx} \quad m = \left[\frac{hP}{kA_c} \right]^{1/2} \quad (1,2)$$

For the two positions prescribed, x_A and x_B , it was observed that

$$T_A(x_A) = T_B(x_B) \quad \text{or} \quad \theta_A(x_A) = \theta_B(x_B). \quad (3)$$

Since θ_b is identical for both rods, Eq. (1) with the equality of Eq. (3) requires that

$$m_A x_A = m_B x_B$$

Substituting for m from Eq. (2) gives

$$\left[\frac{hP}{k_A A_c} \right]^{1/2} x_A = \left[\frac{hP}{k_B A_c} \right]^{1/2} x_B.$$

Recognizing that h , P and A_c are identical for each rod and rearranging,

$$k_B = \left[\frac{x_B}{x_A} \right]^2 k_A$$

$$k_B = \left[\frac{0.075\text{m}}{0.15\text{m}} \right]^2 \times 70 \text{ W/m} \cdot \text{K} = 17.5 \text{ W/m} \cdot \text{K}.$$

<

COMMENTS: This approach has been used as a method for determining the thermal conductivity. It has the attractive feature of not requiring power or temperature measurements, assuming of course, a reference material of known thermal conductivity is available.

PROBLEM 3.128

KNOWN: Dimension and length of an aluminum pin fin. Base and ambient temperatures, value of the convection heat transfer coefficient.

FIND: (a) Fin heat transfer rate with an adiabatic tip, (b) Fin heat transfer rate when the fin tip is cooled below the ambient temperature, (c) Temperature distribution along the fin for parts (a) and (b), (d) Fin heat rates for $0 \leq h \leq 1000 \text{ W/m}^2\cdot\text{K}$.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Steady-state conditions, (3) One-dimensional heat transfer, (4) Negligible radiation heat transfer.

ANALYSIS:

(a) The fin heat transfer rate is given by Eq. 3.76; $q_f = M \tanh ml$ where

$$\begin{aligned} M &= \sqrt{hPkA_c} \theta_b \\ &= \sqrt{1000 \text{ W/m}^2 \cdot \text{K} \times \pi \times 2 \times 10^{-3} \text{ m} \times 140 \text{ W/m} \cdot \text{K} \times \pi \times (2 \times 10^{-3} \text{ m})^2/4 \times (50 - 25)^\circ\text{C}} \\ &= 1.314 \text{ W} \end{aligned}$$

and

$$m = \sqrt{\frac{hP}{kA_c}} = \sqrt{\frac{1000 \text{ W/m}^2 \cdot \text{K} \times \pi \times 2 \times 10^{-3} \text{ m}}{140 \text{ W/m} \cdot \text{K} \times \pi \times (2 \times 10^{-3} \text{ m})^2/4}} = 119.5 \text{ m}^{-1}$$

$$\text{Therefore, } q_f = 1.314 \text{ W} \tanh (119.5 \text{ m}^{-1} \times 40 \times 10^{-3} \text{ m}) = 1.314 \text{ W} \quad <$$

(b) For the case where $T(x = L) = 0^\circ\text{C}$, the fin heat transfer rate is

$$\begin{aligned} q_f &= M \frac{(\cosh ml - \theta_L/\theta_b)}{\sinh ml} \\ &= 1.314 \text{ W} \times \frac{\cosh (119.5 \text{ m}^{-1} \times 40 \times 10^{-3} \text{ m}) - (0 - 25)^\circ\text{C} / (50 - 25)^\circ\text{C}}{\sinh (119.5 \text{ m}^{-1} \times 40 \times 10^{-3} \text{ m})} = 1.336 \text{ W} < \end{aligned}$$

(c) The temperature distributions are found by plotting Eqs. 3.75 and 3.77 over the range $0 \leq x \leq 40 \text{ mm}$. Note, that for the adiabatic tip case, the tip temperature is nearly equal to the

Continued...

PROBLEM 3.128 (Cont.)

ambient temperature. For the cooled tip, the temperature distribution is anti-symmetric about $x = \frac{1}{2} L$. For the cooled tip case and $h = 0$, the temperature distribution in the fin would be linear, corresponding to one-dimensional conduction in the fin.

(d) The fin heat rate distributions are shown below. For adiabatic tip and $h = 0$, $q_f = 0$. For the case of the cooled tip and negligible convection, the fin heat rate is

$$q_f = kA_c(T(x=L) - T_b) / L = (140 \text{ W/m}^2 \cdot \text{K} \times \pi \times (2 \times 10^{-3} \text{ m})^2 / 4) \times ((0 - 50)^{\circ}\text{C} / 40 \times 10^{-3} \text{ m}) = 0.549 \text{ W}.$$

As the convection coefficient increases, the temperatures at $x = \frac{1}{2} L$ approach $T(x = \frac{1}{2} L) = 25^{\circ}\text{C}$ for both the adiabatic and cooled tip cases, resulting in nearly the same fin heat transfer rates. Equations 3.71 and 3.73 would yield the same result for the cooled tip case since heat lost by convection over the range $0 \leq x \leq 20 \text{ mm}$ would be exactly offset by the heat gain by convection over the range $20 \text{ mm} \leq x \leq 40 \text{ mm}$, and heat loss at $x = L$ by conduction is equal to heat gain at $x = 0$ by conduction.

PROBLEM 3.129

KNOWN: Base temperature, ambient fluid conditions, and temperatures at a prescribed distance from the base for two long rods, with one of known thermal conductivity.

FIND: Thermal conductivity of other rod.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along rods, (3) Constant properties, (4) Negligible radiation, (5) Negligible contact resistance at base, (6) Infinitely long rods, (7) Rods are identical except for their thermal conductivity.

ANALYSIS: With the assumption of infinitely long rods, the temperature distribution is

$$\frac{\theta}{\theta_b} = \frac{T - T_\infty}{T_b - T_\infty} = e^{-mx}$$

or

$$\ln \frac{T - T_\infty}{T_b - T_\infty} = -mx = \left[\frac{hP}{kA} \right]^{1/2} x$$

Hence, for the two rods,

$$\frac{\ln \left[\frac{T_A - T_\infty}{T_b - T_\infty} \right]}{\ln \left[\frac{T_B - T_\infty}{T_b - T_\infty} \right]} = \left[\frac{k_B}{k_A} \right]^{1/2}$$

$$k_B^{1/2} = k_A^{1/2} \frac{\ln \left[\frac{T_A - T_\infty}{T_b - T_\infty} \right]}{\ln \left[\frac{T_B - T_\infty}{T_b - T_\infty} \right]} = (200)^{1/2} \frac{\ln \frac{75 - 25}{100 - 25}}{\ln \frac{60 - 25}{100 - 25}} = 7.524$$

$$k_B = 56.6 \text{ W/m} \cdot \text{K}.$$

<

COMMENTS: Providing conditions for the two rods may be maintained nearly identical, the above method provides a convenient means of measuring the thermal conductivity of solids.

PROBLEM 3.130

KNOWN: Arrangement of fins between parallel plates. Temperature and convection coefficient of air flow in finned passages. Maximum allowable plate temperatures.

FIND: (a) Expressions relating fin heat transfer rates to end temperatures. (b) Maximum power dissipation for each plate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fins, (3) Constant properties, (4) Negligible radiation, (5) Uniform h , (6) Negligible variation in T_∞ , (7) Negligible contact resistance.

PROPERTIES: Table A.1, Aluminum (pure), 375 K: $k = 240 \text{ W/m} \cdot \text{K}$.

ANALYSIS: (a) The general solution for the temperature distribution in a fin is

$$\theta(x) = T(x) - T_\infty = C_1 e^{mx} + C_2 e^{-mx}$$

Boundary conditions: $\theta(0) = \theta_o = T_o - T_\infty$, $\theta(L) = \theta_L = T_L - T_\infty$.

$$\text{Hence } \theta_o = C_1 + C_2 \quad \theta_L = C_1 e^{mL} + C_2 e^{-mL}$$

$$\theta_L = C_1 e^{mL} + (\theta_o - C_1) e^{-mL}$$

$$C_1 = \frac{\theta_L - \theta_o e^{-mL}}{e^{mL} - e^{-mL}} \quad C_2 = \theta_o - \frac{\theta_L - \theta_o e^{-mL}}{e^{mL} - e^{-mL}} = \frac{\theta_o e^{mL} - \theta_L}{e^{mL} - e^{-mL}}$$

$$\text{Hence } \theta(x) = \frac{\theta_L e^{mx} - \theta_o e^{m(x-L)} + \theta_o e^{m(L-x)} - \theta_L e^{-mx}}{e^{mL} - e^{-mL}}$$

$$\theta(x) = \frac{\theta_o \left[e^{m(L-x)} - e^{-m(L-x)} \right] + \theta_L \left(e^{mx} - e^{-mx} \right)}{e^{mL} - e^{-mL}}$$

$$\theta(x) = \frac{\theta_o \sinh m(L-x) + \theta_L \sinh mx}{\sinh mL}$$

The fin heat transfer rate is then

$$q_f = -kA_c \frac{dT}{dx} = -kDt \left[-\frac{\theta_o m}{\sinh mL} \cosh m(L-x) + \frac{\theta_L m}{\sinh mL} \cosh mx \right]$$

$$\text{Hence } q_{f,o} = kDt \left(\frac{\theta_o m}{\tanh mL} - \frac{\theta_L m}{\sinh mL} \right) \quad <$$

$$q_{f,L} = kDt \left(\frac{\theta_o m}{\sinh mL} - \frac{\theta_L m}{\tanh mL} \right) \quad <$$

Continued

PROBLEM 3.130 (Cont.)

$$(b) \quad m = \left(\frac{hP}{kA_c} \right)^{1/2} = \left(\frac{150 \text{ W/m}^2 \cdot \text{K} (2 \times 0.1 \text{ m} + 2 \times 0.001 \text{ m})}{240 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.001 \text{ m}} \right)^{1/2} = 35.5 \text{ m}^{-1}$$

$$mL = 35.5 \text{ m}^{-1} \times 0.012 \text{ m} = 0.43$$

$$\sinh mL = 0.439 \quad \tanh mL = 0.401 \quad \theta_o = 100 \text{ K} \quad \theta_L = 50 \text{ K}$$

$$q_{f,o} = 240 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.001 \text{ m} \left(\frac{100 \text{ K} \times 35.5 \text{ m}^{-1}}{0.401} - \frac{50 \text{ K} \times 35.5 \text{ m}^{-1}}{0.439} \right)$$

$$q_{f,o} = 115.4 \text{ W} \quad (\text{from the top plate})$$

$$q_{f,L} = 240 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.001 \text{ m} \left(\frac{100 \text{ K} \times 35.5 \text{ m}^{-1}}{0.439} - \frac{50 \text{ K} \times 35.5 \text{ m}^{-1}}{0.401} \right)$$

$$q_{f,L} = 87.8 \text{ W} \quad (\text{into the bottom plate})$$

Maximum power dissipations are therefore

$$q_{o,\max} = N_f q_{f,o} + (W - N_f t) Dh \theta_o$$

$$q_{o,\max} = 50 \times 115.4 \text{ W} + (0.200 - 50 \times 0.001) \text{ m} \times 0.1 \text{ m} \times 150 \text{ W/m}^2 \cdot \text{K} \times 100 \text{ K}$$

$$q_{o,\max} = 5770 \text{ W} + 225 \text{ W} = 5995 \text{ W} \quad <$$

$$q_{L,\max} = -N_f q_{f,L} + (W - N_f t) Dh \theta_o$$

$$q_{L,\max} = -50 \times 87.8 \text{ W} + (0.200 - 50 \times 0.001) \text{ m} \times 0.1 \text{ m} \times 150 \text{ W/m}^2 \cdot \text{K} \times 50 \text{ K}$$

$$q_{L,\max} = -4390 \text{ W} + 112 \text{ W} = -4278 \text{ W} \quad <$$

COMMENTS: (1) It is of interest to determine the air velocity needed to prevent excessive heating of the air as it passes between the plates. If the air temperature change is restricted to $\Delta T_\infty = 5 \text{ K}$, its flowrate must be

$$\dot{m}_{\text{air}} = \frac{q_{\text{tot}}}{c_p \Delta T_\infty} = \frac{1717 \text{ W}}{1007 \text{ J/kg} \cdot \text{K} \times 5 \text{ K}} = 0.34 \text{ kg/s}.$$

Its mean velocity is then

$$V_{\text{air}} = \frac{\dot{m}_{\text{air}}}{\rho_{\text{air}} A_c} = \frac{0.34 \text{ kg/s}}{1.16 \text{ kg/m}^3 \times 0.012 \text{ m} (0.2 - 50 \times 0.001) \text{ m}} = 163 \text{ m/s}.$$

Such a velocity would be impossible to maintain. To reduce it to a reasonable value, e.g. 10 m/s, A_c would have to be increased substantially by increasing W (and hence the space between fins) and by increasing L . The present configuration is impractical from the standpoint that 1717 W could not be transferred to air in such a small volume.

(2) A negative value of $q_{L,\max}$ implies that the bottom plate must be cooled externally to maintain the plate at 350 K.

PROBLEM 3.131

KNOWN: Conditions associated with an array of straight rectangular fins.

FIND: Thermal resistance of the array.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Uniform convection coefficient, (3) Symmetry about midplane.

ANALYSIS: (a) Considering a one-half section of the array, the corresponding resistance is

$$R_{t,o} = (\eta_o h A_t)^{-1}$$

where $A_t = NA_f + A_b$. With $S = 4$ mm and $t = 1$ mm, it follows that $N = W_1/S = 250$, $A_f = 2(L/2)W_2 = 0.008$ m², $A_b = W_2(W_1 - Nt) = 0.75$ m², and $A_t = 2.75$ m².

The overall surface efficiency is

$$\eta_o = 1 - \frac{NA_f}{A_t}(1 - \eta_f)$$

where the fin efficiency is

$$\eta_f = \frac{\tanh m(L/2)}{m(L/2)} \quad \text{and} \quad m = \left(\frac{hP}{kA_c} \right)^{1/2} = \left[\frac{h(2t + 2W_2)}{ktW_2} \right]^{1/2} \approx \left(\frac{2h}{kt} \right)^{1/2} = 38.7 \text{ m}^{-1}$$

With $m(L/2) = 0.155$, it follows that $\eta_f = 0.992$ and $\eta_o = 0.994$. Hence

$$R_{t,o} = \left(0.994 \times 150 \text{ W/m}^2 \cdot \text{K} \times 2.75 \text{ m}^2 \right)^{-1} = 2.44 \times 10^{-3} \text{ K/W} \quad <$$

(b) The requirements that $t \geq 0.5$ mm and $(S - t) > 2$ mm are based on manufacturing and flow passage restriction constraints. Repeating the foregoing calculations for representative values of t and $(S - t)$, we obtain

S (mm)	N	t (mm)	$R_{t,o}$ (K/W)
2.5	400	0.5	0.00169
3	333	0.5	0.00193
3	333	1	0.00202
4	250	0.5	0.00234
4	250	2	0.00268
5	200	0.5	0.00269
5	200	3	0.00334

COMMENTS: Clearly, the thermal performance of the fin array improves ($R_{t,o}$ decreases) with increasing N . Because $\eta_f \approx 1$ for the entire range of conditions, there is a slight degradation in performance ($R_{t,o}$ increases) with increasing t and fixed N . The reduced performance is associated with the reduction in surface area of the exposed base. Note that the overall thermal resistance for the entire fin array (top and bottom) is $R_{t,o}/2 = 1.22 \times 10^{-2}$ K/W.

PROBLEM 3.132

KNOWN: Dimensions and maximum allowable temperature of an electronic chip. Thermal contact resistance between chip and heat sink. Dimensions and thermal conductivity of heat sink. Temperature and convection coefficient associated with air flow through the heat sink.

FIND: (a) Maximum allowable chip power for heat sink with prescribed number of fins, fin thickness, and fin pitch, and (b) Effect of fin thickness/number and convection coefficient on performance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional heat transfer, (3) Isothermal chip, (4) Negligible heat transfer from top surface of chip, (5) Negligible temperature rise for air flow, (6) Uniform convection coefficient associated with air flow through channels and over outer surfaces of heat sink, (7) Negligible radiation.

ANALYSIS: (a) From the thermal circuit,

$$q_c = \frac{T_c - T_\infty}{R_{\text{tot}}} = \frac{T_c - T_\infty}{R_{t,c} + R_{t,b} + R_{t,o}}$$

where $R_{t,c} = R_{t,c}^* / W^2 = 2 \times 10^{-6} \text{ m}^2 \cdot \text{K} / \text{W} / (0.02 \text{ m})^2 = 0.005 \text{ K} / \text{W}$ and $R_{t,b} = L_b / k (W^2)$
 $= 0.003 \text{ m} / 180 \text{ W} / \text{m} \cdot \text{K} (0.02 \text{ m})^2 = 0.042 \text{ K} / \text{W}$. From Eqs. (3.103), (3.102), and (3.99)

$$R_{t,o} = \frac{1}{\eta_o h A_t}, \quad \eta_o = 1 - \frac{N A_f}{A_t} (1 - \eta_f), \quad A_t = N A_f + A_b$$

where $A_f = 2WL_f = 2 \times 0.02 \text{ m} \times 0.015 \text{ m} = 6 \times 10^{-4} \text{ m}^2$ and $A_b = W^2 - N(tW) = (0.02 \text{ m})^2 - 11(0.182 \times 10^{-3} \text{ m} \times 0.02 \text{ m}) = 3.6 \times 10^{-4} \text{ m}^2$. With $mL_f = (2h/kt)^{1/2} L_f = (200 \text{ W} / \text{m}^2 \cdot \text{K} / 180 \text{ W} / \text{m} \cdot \text{K} \times 0.182 \times 10^{-3} \text{ m})^{1/2} (0.015 \text{ m}) = 1.17$, $\tanh mL_f = 0.824$ and Eq. (3.87) yields

$$\eta_f = \frac{\tanh mL_f}{mL_f} = \frac{0.824}{1.17} = 0.704$$

It follows that $A_t = 6.96 \times 10^{-3} \text{ m}^2$, $\eta_o = 0.719$, $R_{t,o} = 2.00 \text{ K} / \text{W}$, and

$$q_c = \frac{(85 - 20)^\circ \text{C}}{(0.005 + 0.042 + 2.00) \text{ K} / \text{W}} = 31.8 \text{ W} \quad <$$

(b) The following results are obtained from parametric calculations performed to explore the effect of decreasing the number of fins and increasing the fin thickness.

(Continued)

PROBLEM 3.132 (Cont.)

N	t(mm)	η_f	$R_{t,o}$ (K/W)	q_c (W)	A_t (m ²)
6	1.833	0.957	2.76	23.2	0.00378
7	1.314	0.941	2.40	26.6	0.00442
8	0.925	0.919	2.15	29.7	0.00505
9	0.622	0.885	1.97	32.2	0.00569
10	0.380	0.826	1.89	33.5	0.00632
11	0.182	0.704	2.00	31.8	0.00696

Although η_f (and η_o) increases with decreasing N (increasing t), there is a reduction in A_t which yields a minimum in $R_{t,o}$, and hence a maximum value of q_c , for $N = 10$. For $N = 11$, the effect of h on the performance of the heat sink is shown below.

With increasing h from 100 to 1000 W/m²·K, $R_{t,o}$ decreases from 2.00 to 0.47 K/W, despite a decrease in η_f (and η_o) from 0.704 (0.719) to 0.269 (0.309). The corresponding increase in q_c is significant.

COMMENTS: The heat sink significantly increases the allowable heat dissipation. If it were not used and heat was simply transferred by convection from the surface of the chip with $h = 100$ W/m²·K, $R_{tot} = 2.05$ K/W from Part (a) would be replaced by $R_{env} = 1/hW^2 = 25$ K/W, yielding $q_c = 2.60$ W.

PROBLEM 3.133

KNOWN: Dimensions of electronics package and finned nano-heat sink. Temperature and heat transfer coefficient of coolant.

FIND: Maximum heat rate to maintain temperature below 85°C for finned and un-finned packages.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible temperature variation across fin thickness, (3) Constant properties, (4) Uniform heat transfer coefficient, (5) Negligible contact resistance, (6) Negligible heat loss from edges of package.

PROPERTIES: Table A.2, Silicon carbide ($T \approx 300$ K): $k = 490$ W/m·K.

ANALYSIS: (a) The thermal circuit for the un-finned package is

$$\text{where } R_{\text{cond}} = \frac{d}{kA} = \frac{100 \times 10^{-9} \text{ m}}{490 \text{ W/m} \cdot \text{K} \times (10 \times 10^{-6} \text{ m})^2} = 2.04 \text{ K/W}$$

$$R_{\text{conv}} = \frac{1}{hA} = \frac{1}{10^5 \text{ W/m}^2 \cdot \text{K} \times (10 \times 10^{-6} \text{ m})^2} = 1 \times 10^5 \text{ K/W}$$

$$\text{Thus } q = 2 \frac{(T_t - T_\infty)}{R_{\text{cond}} + R_{\text{conv}}} = 2 \frac{(85^\circ\text{C} - 20^\circ\text{C})}{(2.04 + 10^5) \text{ K/W}} = 1.30 \times 10^{-3} \text{ W}$$

<

Continued...

PROBLEM 3.133 (Cont.)

For the finned nano-heat sink, the convection resistance is replaced by a fin array thermal resistance:

From Equations 3.103, 3.102, and 3.99

$$R_{t,o} = \frac{1}{\eta_o h A_t}, \quad \eta_o = 1 - \frac{N A_f}{A_t} (1 - \eta_f), \quad A_t = N A_f + A_b$$

where $A_f = \pi D L_c = \pi D (L + D/4) = \pi \times 15 \times 10^{-9} \text{ m} \times (300 + 15/4) \times 10^{-9} \text{ m} = 1.43 \times 10^{-14} \text{ m}^2$,

$A_b = W^2 - N \pi D^2/4 = (10 \times 10^{-6} \text{ m})^2 - 40,000 \times \pi \times (15 \times 10^{-9} \text{ m})^2/4 = 9.29 \times 10^{-11} \text{ m}^2$, and

$A_t = 40,000 \times 1.43 \times 10^{-14} \text{ m}^2 + 9.29 \times 10^{-11} \text{ m}^2 = 6.65 \times 10^{-10} \text{ m}^2$. Then with

$m L_c = (4h/kD)^{1/2} L_c = (4 \times 10^5 \text{ W/m}^2 \cdot \text{K} / 490 \text{ W/m} \cdot \text{K} \times 15 \times 10^{-9} \text{ m})^{1/2} \times 304 \times 10^{-9} \text{ m} = 7.09 \times 10^{-2}$,

$$\eta_f = \frac{\tanh(m L_c)}{m L_c} = \frac{\tanh(7.09 \times 10^{-2})}{7.09 \times 10^{-2}} = 0.998$$

It follows that

$$\eta_o = 1 - \frac{40,000 \times 1.43 \times 10^{-14} \text{ m}^2}{6.65 \times 10^{-10} \text{ m}^2} (1 - 0.998) = 0.999$$

and

$$R_{t,o} = \frac{1}{0.999 \times 10^5 \text{ W/m}^2 \cdot \text{K} \times 6.65 \times 10^{-10} \text{ m}^2} = 1.50 \times 10^4 \text{ K/W}$$

Therefore

$$q = 2 \frac{(T_t - T_\infty)}{R_{\text{cond}} + R_{t,o}} = 2 \frac{(85^\circ\text{C} - 20^\circ\text{C})}{2.04 \text{ K/W} + 1.50 \times 10^4 \text{ K/W}} = 8.64 \times 10^{-3} \text{ W} <$$

COMMENTS: (1) The conduction resistance of the silicon carbide sheets is negligible. (2) The fins increase the allowable heat rate significantly. (3) We have neglected the contact resistance between the electronics and the silicon carbide sheets. If it dominates, the fins will not be effective in increasing the allowable heat rate. Little is known about contact resistance at the nanoscale.

PROBLEM 3.134

KNOWN: Geometry and cooling arrangement for a chip-circuit board arrangement. Maximum chip temperature.

FIND: (a) Equivalent thermal circuit, (b) Maximum chip heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in chip-board assembly, (3) Negligible pin-chip contact resistance, (4) Constant properties, (5) Negligible chip thermal resistance, (6) Uniform chip temperature.

PROPERTIES: Table A.1, Copper (300 K): $k \approx 400$ W/m·K.

ANALYSIS: (a) The thermal circuit is

$$R_f = \frac{\theta_b}{16q_f} = \frac{\cosh mL + (h_o/mk) \sinh mL}{16(h_o P k A_{c,f})^{1/2} [\sinh mL + (h_o/mk) \cosh mL]}$$

(b) The maximum chip heat rate is

$$q_c = 16q_f + q_b + q_i$$

Evaluate these parameters

$$m = \left(\frac{h_o P}{k A_{c,f}} \right)^{1/2} = \left(\frac{4h_o}{k D_p} \right)^{1/2} = \left(\frac{4 \times 1000 \text{ W/m}^2 \cdot \text{K}}{400 \text{ W/m} \cdot \text{K} \times 0.0015 \text{ m}} \right)^{1/2} = 81.7 \text{ m}^{-1}$$

$$mL = (81.7 \text{ m}^{-1} \times 0.015 \text{ m}) = 1.23, \quad \sinh mL = 1.57, \quad \cosh mL = 1.86$$

$$(h_o/mk) = \frac{1000 \text{ W/m}^2 \cdot \text{K}}{81.7 \text{ m}^{-1} \times 400 \text{ W/m} \cdot \text{K}} = 0.0306$$

$$M = \left(h_o \pi D_p k \pi D_p^2 / 4 \right)^{1/2} \theta_b$$

$$M = \left[1000 \text{ W/m}^2 \cdot \text{K} \left(\pi^2 / 4 \right) (0.0015 \text{ m})^3 400 \text{ W/m} \cdot \text{K} \right]^{1/2} (55^\circ \text{C}) = 3.17 \text{ W}$$

Continued

PROBLEM 3.134 (Cont.)

The fin heat rate is

$$q_f = M \frac{\sinh mL + (h_o/mk) \cosh mL}{\cosh mL + (h_o/mk) \sinh mL} = 3.17 \text{ W} \frac{1.57 + 0.0306 \times 1.86}{1.86 + 0.0306 \times 1.57}$$

$$q_f = 2.703 \text{ W}.$$

The heat rate from the chip top by convection is

$$q_b = h_o A_b \theta_b = 1000 \text{ W/m}^2 \cdot \text{K} \left[(0.0127 \text{ m})^2 - (16\pi/4)(0.0015 \text{ m})^2 \right] 55^\circ \text{C}$$

$$q_b = 7.32 \text{ W}.$$

The convection heat rate from the board is

$$q_i = \frac{T_c - T_{\infty,i}}{(1/h_i + R''_{t,c} + L_b/k_b)(1/A_c)} = \frac{(0.0127 \text{ m})^2 (55^\circ \text{C})}{(1/40 + 10^{-4} + 0.005/1) \text{ m}^2 \cdot \text{K/W}}$$

$$q_i = 0.29 \text{ W}.$$

Hence, the maximum chip heat rate is

$$q_c = [16(2.703) + 7.32 + 0.29] \text{ W} = [43.25 + 7.32 + 0.29] \text{ W}$$

$$q_c = 50.9 \text{ W}.$$

<

COMMENTS: (1) The fins are extremely effective in enhancing heat transfer from the chip

(assuming negligible contact resistance). Their effectiveness is $\varepsilon = q_f / \left(\pi D_p^2 / 4 \right) h_o \theta_b = 2.703$
 $\text{W}/0.097 \text{ W} = 27.8$

(2) Without the fins, $q_c = 1000 \text{ W/m}^2 \cdot \text{K} (0.0127 \text{ m})^2 55^\circ \text{C} + 0.29 \text{ W} = 9.16 \text{ W}$. Hence the fins provide for a $(50.9 \text{ W}/9.16 \text{ W}) \times 100\% = 555\%$ enhancement of heat transfer.

(3) With the fins, the chip heat flux is $50.9 \text{ W}/(0.0127 \text{ m})^2$ or $q_c'' = 3.16 \times 10^5 \text{ W/m}^2 = 31.6 \text{ W/cm}^2$.

(4) If the infinite fin approximation is made, $q_f = M = 3.17 \text{ W}$, and the actual fin heat transfer is overestimated by 17%.

PROBLEM 3.135

KNOWN: Geometry of pin fin array used as heat sink for a computer chip. Array convection and chip substrate conditions.

FIND: Effect of pin diameter, spacing and length on maximum allowable chip power dissipation.

SCHEMATIC:

Physical System:

Thermal Circuit:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in chip-board assembly, (3) Negligible pin-chip contact resistance, (4) Constant properties, (5) Negligible chip thermal resistance, (6) Uniform chip temperature.

ANALYSIS: The total power dissipation is $q_c = q_i + q_t$, where

$$q_i = \frac{T_c - T_{\infty,i}}{\left(1/h_i + R''_{t,c} + L_b/k_b\right)/A_c} = 0.3 \text{ W}$$

and

$$q_t = \frac{T_c - T_{\infty,o}}{R_{t,o}}$$

The resistance of the pin array is

$$R_{t,o} = (\eta_o h_o A_t)^{-1}$$

where

$$\eta_o = 1 - \frac{NA_f}{A_t} (1 - \eta_f)$$

$$A_t = NA_f + A_b$$

$$A_f = \pi D_p L_c = \pi D_p (L_p + D_p/4)$$

Subject to the constraint that $N^{1/2} D_p \leq 9 \text{ mm}$, the foregoing expressions may be used to compute q_c as a function of D_p for $L_p = 15 \text{ mm}$ and values of $N = 16, 25$ and 36 . Using the *IHT Performance*

Calculation, Extended Surface Model for the *Pin Fin Array*, we obtain

Continued...

PROBLEM 3.135 (Cont.)

Clearly, it is desirable to maximize the number of pins and the pin diameter, so long as flow passages are not constricted to the point of requiring an excessive pressure drop to maintain the prescribed convection coefficient. The maximum heat rate for the fin array ($q_t = 33.1$ W) corresponds to $N = 36$ and $D_p = 1.5$ mm. Further improvement could be obtained by using $N = 49$ pins of diameter $D_p = 1.286$ mm, which yield $q_t = 37.7$ W.

Exploring the effect of L_p for $N = 36$ and $D_p = 1.5$ mm, we obtain

Clearly, there are benefits to increasing L_p , although the effect diminishes due to an attendant reduction in η_f (from $\eta_f = 0.887$ for $L_p = 15$ mm to $\eta_f = 0.471$ for $L_p = 50$ mm). Although a heat dissipation rate of $q_t = 56.7$ W is obtained for $L_p = 50$ mm, package volume constraints could preclude such a large fin length.

COMMENTS: By increasing N , D_p and/or L_p , the total surface area of the array, A_t , is increased, thereby reducing the array thermal resistance, $R_{t,o}$. The effects of D_p and N are shown for $L_p = 15$ mm.

PROBLEM 3.136

KNOWN: Copper heat sink dimensions and convection conditions.

FIND: (a) Maximum allowable heat dissipation for a prescribed chip temperature and interfacial chip/heat-sink contact resistance, (b) Effect of fin length and width on heat dissipation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in chip-heat sink assembly, (3) Constant k , (4) Negligible chip thermal resistance, (5) Negligible heat transfer from back of chip, (6) Uniform chip temperature.

ANALYSIS: (a) For the prescribed system, the chip power dissipation may be expressed as

$$q_c = \frac{T_c - T_\infty}{R_{t,c} + R_{cond,b} + R_{t,o}}$$

$$\text{where } R_{t,c} = \frac{R''_{t,c}}{W_c^2} = \frac{5 \times 10^{-6} \text{ m}^2 \cdot \text{K/W}}{(0.016 \text{ m})^2} = 0.0195 \text{ K/W}$$

$$R_{cond,b} = \frac{L_b}{kW_c^2} = \frac{0.003 \text{ m}}{400 \text{ W/m} \cdot \text{K} (0.016 \text{ m})^2} = 0.0293 \text{ K/W}$$

The thermal resistance of the fin array is

$$R_{t,o} = (\eta_o h A_t)^{-1}$$

$$\text{where } \eta_o = 1 - \frac{N A_f}{A_t} (1 - \eta_f)$$

$$\text{and } A_t = N A_f + A_b = N (4 w L_c) + (W_c^2 - N w^2)$$

Continued...

PROBLEM 3.136 (Cont.)

With $w = 0.25$ mm, $S = 0.50$ mm, $L_f = 6$ mm, $N = 1024$, and $L_c \approx L_f + w/4 = 6.063 \times 10^{-3}$ m, it follows that $A_f = 6.06 \times 10^{-6} \text{ m}^2$ and $A_t = 6.40 \times 10^{-3} \text{ m}^2$. The fin efficiency is

$$\eta_f = \frac{\tanh mL_c}{mL_c}$$

where $m = (hP/kA_c)^{1/2} = (4h/kw)^{1/2} = 245 \text{ m}^{-1}$ and $mL_c = 1.49$. It follows that $\eta_f = 0.608$ and $\eta_o = 0.619$, in which case

$$R_{t,o} = \left(0.619 \times 1500 \text{ W/m}^2 \cdot \text{K} \times 6.40 \times 10^{-3} \text{ m}^2 \right) = 0.168 \text{ K/W}$$

and the maximum allowable heat dissipation is

$$q_c = \frac{(85 - 25)^\circ \text{C}}{(0.0195 + 0.0293 + 0.168) \text{ K/W}} = 276 \text{ W}$$

<

(b) The IHT *Performance Calculation, Extended Surface Model* for the *Pin Fin Array* has been used to determine q_c as a function of L_f for four different cases, each of which is characterized by the closest allowable fin spacing of $(S - w) = 0.25$ mm.

Case	w (mm)	S (mm)	N
A	0.25	0.50	1024
B	0.35	0.60	711
C	0.45	0.70	522
D	0.55	0.80	400

With increasing w and hence decreasing N , there is a reduction in the total area A_t associated with heat transfer from the fin array. However, for Cases A through C, the reduction in A_t is more than balanced by an increase in η_f (and η_o), causing a reduction in $R_{t,o}$ and hence an increase in q_c . As the fin efficiency approaches its limiting value of $\eta_f = 1$, reductions in A_t due to increasing w are no longer balanced by increases in η_f , and q_c begins to decrease. Hence there is an optimum value of w , which depends on L_f . For the conditions of this problem, $L_f = 10$ mm and $w = 0.55$ mm provide the largest heat dissipation.

Problem 3.137

KNOWN: Two finned heat sinks, Designs A and B, prescribed by the number of fins in the array, N , fin dimensions of square cross-section, w , and length, L , with different convection coefficients, h .

FIND: Determine which fin arrangement is superior. Calculate the heat rate, q_f , efficiency, η_f , and effectiveness, ϵ_f , of a single fin, as well as, the total heat rate, q_t , and overall efficiency, η_o , of the array. Also, compare the total heat rates per unit volume.

SCHEMATIC:

Design	Fin dimensions		Number of fins	Convection coefficient ($\text{W}/\text{m}^2\cdot\text{K}$)
	Cross section $w \times w$ (mm)	Length L (mm)		
A	3 x 3	30	6 x 9	125
B	1 x 1	7	14 x 17	375

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fins, (3) Convection coefficient is uniform over fin and prime surfaces, (4) Fin tips experience convection, and (5) Constant properties.

ANALYSIS: Following the treatment of Section 3.6.5, the overall efficiency of the array, Eq. (3.98), is

$$\eta_o = \frac{q_t}{q_{\max}} = \frac{q_t}{hA_t\theta_b} \quad (1)$$

where A_t is the total surface area, the sum of the exposed portion of the base (prime area) plus the fin surfaces, Eq. 3.99,

$$A_t = N \cdot A_f + A_b \quad (2)$$

where the surface area of a single fin and the prime area are

$$A_f = 4(L \times w) + w^2 \quad (3)$$

$$A_b = b_1 \times b_2 - N \cdot A_c \quad (4)$$

Combining Eqs. (1) and (2), the total heat rate for the array is

$$q_t = N\eta_f hA_f\theta_b + hA_b\theta_b \quad (5)$$

where η_f is the efficiency of a single fin. From Table 4.3, Case A, for the tip condition with convection, the single fin efficiency based upon Eq. 3.86,

$$\eta_f = \frac{q_f}{hA_f\theta_b} \quad (6)$$

Continued...

PROBLEM 3.137 (Cont.)

where

$$q_f = M \frac{\sinh(mL) + (h/mk) \cosh(mL)}{\cosh(mL) + (h/mk) \sinh(mL)} \quad (7)$$

$$M = (hPkA_c)^{1/2} \theta_b \quad m = (hP/kA_c)^{1/2} \quad P = 4w \quad A_c = w^2 \quad (8,9,10)$$

The single fin effectiveness, from Eq. 3.81,

$$\varepsilon_f = \frac{q_f}{hA_c\theta_b} \quad (11)$$

Additionally, we want to compare the performance of the designs with respect to the array volume,

$$q_f''' = q_t/\mathcal{V} = q_t/(b_1 \cdot b_2 \cdot L) \quad (12)$$

The above analysis was organized for easy treatment with equation-solving software. Solving Eqs. (1) through (11) simultaneously with appropriate numerical values, the results are tabulated below.

Design	q_t (W)	q_f (W)	η_o	η_f	ε_f	q_f''' (W/m ³)
A	113	1.80	0.804	0.779	31.9	1.25×10^6
B	165	0.475	0.909	0.873	25.3	7.81×10^6

COMMENTS: (1) Both designs have good efficiencies and effectiveness. Clearly, Design B is superior because the heat rate is nearly 50% larger than Design A for the same board footprint. Further, the space requirement for Design B is four times less ($\mathcal{V} = 2.12 \times 10^{-5}$ vs. 9.06×10^{-5} m³) and the heat rate per unit volume is 6 times greater.

(2) Design A features 54 fins compared to 238 fins for Design B. Also very significant to the performance comparison is the magnitude of the convection coefficient which is 3 times larger for Design B. Estimating convection coefficients for fin arrays (and tube banks) is discussed in Chapter 7.6. Of concern is how the upstream fins alter the flow past the downstream fins and whether the convection coefficient is uniform over the array.

(3) The *IHT Extended Surfaces Model*, for a *Rectangular Pin Fin Array* could have been used to solve this problem.

PROBLEM 3.138

KNOWN: Dimensions of a fin array and dust layer. Aluminum and dust thermal conductivities. Base temperature. Air temperature and heat transfer coefficient.

FIND: Allowable heat rate for dust layer thickness in the range of $0 \leq L_d \leq 5$ mm.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible temperature variation across fin thickness, (3) Constant properties, (4) Uniform heat transfer coefficient, including over fin tips.

ANALYSIS: There are two heat transfer paths, one through the dust and into the air, and the other through the fin. The thermal circuit is

The thermal resistances are given by

$$R_{d,cond} = \frac{L_d}{k_d A_d} = \frac{L_d}{k_d (A_p - N A_c)}$$

where $A_p = 53 \times 10^{-3} \text{ m} \times 57 \times 10^{-3} \text{ m} = 3.02 \times 10^{-3} \text{ m}^2$, $N = 14 \times 17 = 238$ and $A_c = w^2 = 10^{-6} \text{ m}^2$.

$$R_{conv} = \frac{1}{h A_d}, \quad R_{f,cond} = \frac{L_d}{k_f N A_c} \quad \text{and} \quad R_{fins} = \frac{R_{t,f}}{N}$$

where from Equation 3.83

$$R_{t,f} = \frac{\theta_b}{q_f}$$

where q_f is given by Equation 3.72,

$$R_{t,f} = \frac{\cosh(m L_f) + (h / m k_f) \sinh(m L_f)}{\sqrt{4 h w^3 k} (\sinh(m L_f) + (h / m k_f) \cosh(m L_f))}$$

Continued...

PROBLEM 3.138 (Cont.)

Here, $m = (4h / k_{fw})^{1/2} = (4 \times 375 \text{ W/m}^2\cdot\text{K} / 175 \text{ W/m}\cdot\text{K} \times 10^{-3} \text{ m})^{1/2} = 92.6 \text{ m}^{-1}$

and $L_f = L - L_d$.

Finally,

$$q = q_{\text{dust}} + q_{\text{fin}} = \frac{T_b - T_\infty}{R_{d,\text{cond}} + R_{\text{conv}}} + \frac{T_b - T_\infty}{R_{f,\text{cond}} + R_{f,\text{fins}}}$$

Performing the calculation for a dust layer thickness of $L_d = 5 \text{ mm}$ yields

$$R_{d,\text{cond}} = 56.1 \text{ K/W}$$

$$R_{\text{conv}} = 0.958 \text{ K/W}$$

$$R_{f,\text{cond}} = 0.120 \text{ K/W}$$

$$R_{t,f} = 301 \text{ K/W}, \quad R_{f,\text{fins}} = 1.26 \text{ K/W}$$

$$q = \frac{75^\circ\text{C} - 25^\circ\text{C}}{(56.1 + 0.958) \text{ K/W}} + \frac{75^\circ\text{C} - 25^\circ\text{C}}{0.120 + 1.26} = 0.876 \text{ W} + 36.1 \text{ W} = 37.0 \text{ W}$$

<

The figure shows the variation of the allowable heat rate as the dust layer thickness varies.

COMMENTS: The figure below shows the two contributions to the heat rate, q_{dust} and q_{fin} . The heat transfer through the dust layer decreases rapidly as the dust layer thickness increases and insulates the surface. The fin heat transfer also decreases with increasing dust layer thickness as more of the fin surface is insulated by the dust.

PROBLEM 3.138 (Cont.)

PROBLEM 3.139

KNOWN: Long rod with internal volumetric generation covered by an electrically insulating sleeve and supported with a ribbed spider.

FIND: Combination of convection coefficient, spider design, and sleeve thermal conductivity which enhances volumetric heating subject to a maximum centerline temperature of 100°C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial heat transfer in rod, sleeve and hub, (3) Negligible interfacial contact resistances, (4) Constant properties, (5) Adiabatic outer surface.

ANALYSIS: The system heat rate per unit length may be expressed as

$$q' = \dot{q}(\pi r_o^2) = \frac{T_1 - T_\infty}{R'_{\text{sleeve}} + R'_{\text{hub}} + R'_{t,o}}$$

where

$$R'_{\text{sleeve}} = \frac{\ln(r_1/r_o)}{2\pi k_s}, \quad R'_{\text{hub}} = \frac{\ln(r_2/r_1)}{2\pi k_r} = 3.168 \times 10^{-4} \text{ m} \cdot \text{K/W}, \quad R'_{t,o} = \frac{1}{\eta_o h A'_t},$$

$$\eta_o = 1 - \frac{N A'_f}{A'_t} (1 - \eta_f), \quad A'_f = 2(r_3 - r_2), \quad A'_t = N A'_f + (2\pi r_3 - N t),$$

$$\eta_f = \frac{\tanh m(r_3 - r_2)}{m(r_3 - r_2)}, \quad m = (2h/k_r t)^{1/2}.$$

The rod centerline temperature is related to T_1 through

$$T_o = T(0) = T_1 + \frac{\dot{q} r_o^2}{4k}$$

Calculations may be expedited by using the IHT *Performance Calculation, Extended Surface Model* for the *Straight Fin Array*. For base case conditions of $k_s = 0.5 \text{ W/m} \cdot \text{K}$, $h = 20 \text{ W/m}^2 \cdot \text{K}$, $t = 4 \text{ mm}$ and $N = 12$, $R'_{\text{sleeve}} = 0.0580 \text{ m} \cdot \text{K/W}$, $R'_{t,o} = 0.0826 \text{ m} \cdot \text{K/W}$, $\eta_f = 0.990$, $q' = 387 \text{ W/m}$, and $\dot{q} = 1.23 \times 10^6 \text{ W/m}^3$. As shown below, \dot{q} may be increased by increasing h , where $h = 250 \text{ W/m}^2 \cdot \text{K}$ represents a reasonable upper limit for airflow. However, a more than 10-fold increase in h yields only a 63% increase in \dot{q} .

Continued...

PROBLEM 3.139 (Cont.)

The difficulty is that, by significantly increasing h , the thermal resistance of the fin array is reduced to 0.00727 m·K/W, rendering the sleeve the dominant contributor to the total resistance.

Similar results are obtained when N and t are varied. For values of $t = 2, 3$ and 4 mm, variations of N in the respective ranges $12 \leq N \leq 26$, $12 \leq N \leq 21$ and $12 \leq N \leq 17$ were considered. The upper limit on N was fixed by requiring that $(S - t) \geq 2 \text{ mm}$ to avoid an excessive resistance to airflow between the ribs. As shown below, the effect of increasing N is small, and there is little difference between results for the three values of t .

In contrast, significant improvement is associated with changing the sleeve material, and it is only necessary to have $k_s \approx 25 \text{ W/m·K}$ (e.g. a boron sleeve) to approach an upper limit to the influence of k_s .

For $h = 250 \text{ W/m}^2\text{·K}$ and $k_s = 25 \text{ W/m·K}$, only a slight improvement is obtained by increasing N . Hence, the recommended conditions are:

$$h = 250 \text{ W/m}^2\text{·K}, \quad k_s = 25 \text{ W/m·K}, \quad N = 12, \quad t = 4 \text{ mm} \quad \leftarrow$$

COMMENTS: The upper limit to \dot{q} is reached as the total thermal resistance approaches zero, in which case $T_1 \rightarrow T_\infty$. Hence $\dot{q}_{\max} = 4k(T_0 - T_\infty)/r_0^2 = 4.5 \times 10^6 \text{ W/m}^3$.

PROBLEM 3.140

KNOWN: Geometrical and convection conditions of internally finned, concentric tube air heater.

FIND: (a) Thermal circuit, (b) Heat rate per unit tube length, (c) Effect of changes in fin array.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in radial direction, (3) Constant k , (4) Adiabatic outer surface.

ANALYSIS: (a) For the thermal circuit shown schematically,

$$R'_{\text{conv},i} = (h_i 2\pi r_1)^{-1}, \quad R'_{\text{cond}} = \ln(r_2/r_1)/2\pi k, \quad \text{and} \quad R'_{t,o} = (\eta_o h_o A'_t)^{-1},$$

where

$$\eta_o = 1 - \frac{NA'_f}{A'_t} (1 - \eta_f), \quad A'_f = 2L = 2(r_3 - r_2), \quad A'_t = NA'_f + (2\pi r_2 - Nt), \quad \text{and} \quad \eta_f = \frac{\tanh mL}{mL}.$$

$$(b) \quad q' = \frac{(T_{\infty,i} - T_{\infty,o})}{R'_{\text{conv},i} + R'_{\text{cond}} + R'_{t,o}}$$

Substituting the known conditions, it follows that

$$R'_{\text{conv},i} = \left(5000 \text{ W/m}^2 \cdot \text{K} \times 2\pi \times 0.013 \text{ m} \right)^{-1} = 2.45 \times 10^{-3} \text{ m} \cdot \text{K/W}$$

$$R'_{\text{cond}} = \ln(0.016 \text{ m}/0.013 \text{ m}) / 2\pi (20 \text{ W/m} \cdot \text{K}) = 1.65 \times 10^{-3} \text{ m} \cdot \text{K/W}$$

$$R'_{t,o} = \left(0.575 \times 200 \text{ W/m}^2 \cdot \text{K} \times 0.461 \text{ m} \right)^{-1} = 18.86 \times 10^{-3} \text{ m} \cdot \text{K/W}$$

where $\eta_f = 0.490$. Hence,

$$q' = \frac{(90 - 25)^\circ \text{C}}{(2.45 + 1.65 + 18.86) \times 10^{-3} \text{ m} \cdot \text{K/W}} = 2831 \text{ W/m} \quad <$$

(c) The small value of η_f suggests that some benefit may be gained by increasing t , as well as by increasing N . With the requirement that $Nt \leq 50 \text{ mm}$, we use the IHT *Performance Calculation, Extended Surface Model* for the *Straight Fin Array* to consider the following range of conditions: $t = 2 \text{ mm}$, $12 \leq N \leq 25$; $t = 3 \text{ mm}$, $8 \leq N \leq 16$; $t = 4 \text{ mm}$, $6 \leq N \leq 12$; $t = 5 \text{ mm}$, $5 \leq N \leq 10$. Calculations based on the foregoing model are plotted as follows.

Continued...

PROBLEM 3.140 (Cont.)

By increasing t from 2 to 5 mm, η_f increases from 0.410 to 0.598. Hence, for fixed N , q' increases with increasing t . However, from the standpoint of maximizing q'_t , it is clearly preferable to use the larger number of thinner fins. Hence, subject to the prescribed constraint, we would choose $t = 2$ mm and $N = 25$, for which $q' = 4880$ W/m.

COMMENTS: (1) The air side resistance makes the dominant contribution to the total resistance, and efforts to increase q' by reducing $R'_{t,o}$ are well directed. (2) A fin thickness any smaller than 2 mm would be difficult to manufacture.

PROBLEM 3.141

KNOWN: Dimensions and number of rectangular aluminum fins. Convection coefficient with and without fins.

FIND: Percentage increase in heat transfer resulting from use of fins.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Negligible fin contact resistance, (6) Uniform convection coefficient.

PROPERTIES: Table A-1, Aluminum, pure: $k \approx 240\text{ W/m} \cdot \text{K}$.

ANALYSIS: Evaluate the fin parameters

$$L_c = L + t/2 = 0.05025\text{ m}$$

$$A_p = L_c t = 0.05025\text{ m} \times 0.5 \times 10^{-3}\text{ m} = 25.13 \times 10^{-6}\text{ m}^2$$

$$L_c^{3/2} (h_w / k A_p)^{1/2} = (0.05025\text{ m})^{3/2} \left[\frac{30\text{ W/m}^2 \cdot \text{K}}{240\text{ W/m} \cdot \text{K} \times 25.13 \times 10^{-6}\text{ m}^2} \right]^{1/2}$$

$$L_c^{3/2} (h_w / k A_p)^{1/2} = 0.794$$

It follows from Fig. 3.18 that $\eta_f \approx 0.72$. Hence,

$$q_f = \eta_f q_{\max} = 0.72 h_w 2wL \theta_b$$

$$q_f = 0.72 \times 30\text{ W/m}^2 \cdot \text{K} \times 2 \times 0.05\text{ m} \times (w \theta_b) = 2.16\text{ W/m} \cdot \text{K} (w \theta_b)$$

With the fins, the heat transfer from the walls is

$$q_w = N q_f + (1 - Nt) w h_w \theta_b$$

$$q_w = 250 \times 2.16 \frac{\text{W}}{\text{m} \cdot \text{K}} (w \theta_b) + (1 - 250 \times 5 \times 10^{-4}) \times 30\text{ W/m}^2 \cdot \text{K} (w \theta_b)$$

$$q_w = (540 + 26.3) \frac{\text{W}}{\text{m} \cdot \text{K}} (w \theta_b) = 566 w \theta_b.$$

Without the fins, $q_{wo} = h_{wo} 1\text{ m} \times w \theta_b = 40 w \theta_b$. Hence the percentage increase in heat transfer is

$$\frac{q_w - q_{wo}}{q_{wo}} = \frac{(566 - 40) w \theta_b}{40 w \theta_b} = 13.15 = 1315\% \quad <$$

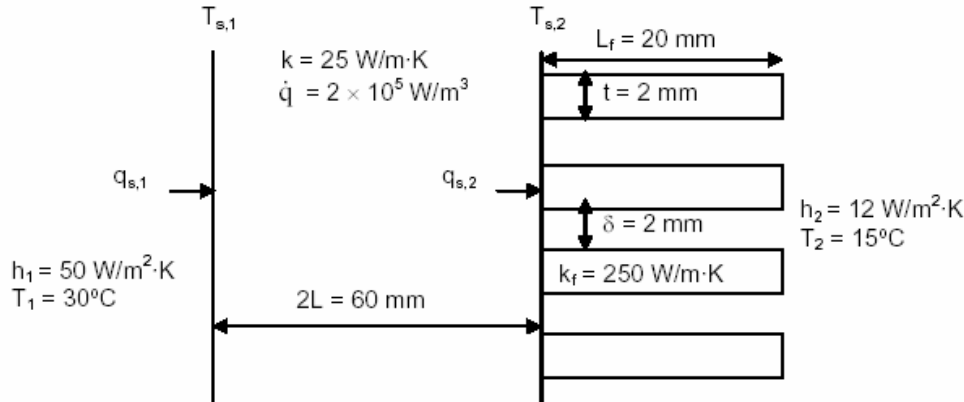

COMMENTS: If the infinite fin approximation is made, it follows that $q_f = (h P k A_c)^{1/2} \theta_b = [h_w 2w k t]^{1/2} \theta_b = (30 \times 2 \times 240 \times 5 \times 10^{-4})^{1/2} w \theta_b = 2.68 w \theta_b$. Hence, q_f is overestimated.

PROBLEM 3.142

KNOWN: Wall with known heat generation rate, thermal conductivity, and thickness. Dimensions and thermal conductivity of fins. Heat transfer coefficients and environment temperatures.

FIND: Maximum temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Wall surface temperatures are uniform, (3) No contact resistance between fins and wall, (4) Heat transfer from the fin tips can be neglected.

ANALYSIS: The temperature distribution in a wall with uniform volumetric heat generation and specified temperature boundary conditions is, from Equation 3.41

$$T(x) = \frac{\dot{q}L^2}{2k} \left(1 - \frac{x^2}{L^2} \right) + \frac{T_{s,2} - T_{s,1}}{2} \frac{x}{L} + \frac{T_{s,1} + T_{s,2}}{2} \quad (1)$$

The heat transfer rates at the two surfaces, for a wall section of area A , can be found from Fourier's Law:

$$q_{s,1} = -kA \left. \frac{dT}{dx} \right|_{x=-L} = -\dot{q}LA - kA \frac{T_{s,2} - T_{s,1}}{2L} \quad (2)$$

$$q_{s,2} = -kA \left. \frac{dT}{dx} \right|_{x=L} = \dot{q}LA - kA \frac{T_{s,2} - T_{s,1}}{2L} \quad (3)$$

We can express these same heat transfer rates alternatively, as follows:

$$q_{s,1} = h_1 A (T_1 - T_{s,1}) \quad (4)$$

$$q_{s,2} = h_2 A_t (T_{s,2} - T_2) \eta_o \quad (5)$$

where η_o is given by Equation 3.102. Equating the two expressions for $q_{s,1}$, Equations (2) and (4), and equating the expressions for $q_{s,2}$, Equations (3) and (5), and solving for $T_{s,1}$ and $T_{s,2}$ yields

Continued...

PROBLEM 3.142 (Cont.)

$$T_{s,1} = \frac{\left(\frac{k}{2L} + h_2\tilde{A}\right)h_1T_1 + \frac{k}{2L}h_2\tilde{A}T_2 + \left(\frac{k}{L} + h_2\tilde{A}\right)\dot{q}L}{\frac{kh_1}{2L} + h_1h_2\tilde{A} + \frac{kh_2\tilde{A}}{2L}}$$

$$T_{s,2} = \frac{\frac{k}{2L}h_1T_1 + \left(\frac{k}{2L} + h_1\right)h_2\tilde{A}T_2 + \left(\frac{k}{L} + h_1\right)\dot{q}L}{\frac{kh_1}{2L} + h_1h_2\tilde{A} + \frac{kh_2\tilde{A}}{2L}}$$

where

$$\tilde{A} = \frac{A_t\eta_o}{A} = \frac{A_t}{A} - \frac{NA_f}{A}(1 - \eta_f)$$

Performing the calculations:

$$m = \sqrt{\frac{h_2P}{k_fA_c}} = \sqrt{\frac{2h_2}{k_ft}} = \sqrt{\frac{2 \times 12 \text{ W/m}^2 \cdot \text{K}}{250 \text{ W/m} \cdot \text{K} \times 0.002 \text{ m}}} = 6.9 \text{ m}^{-1}$$

$$\eta_f = \frac{\tanh(mL_f)}{mL_f} = \frac{\tanh(6.9 \text{ m}^{-1} \times 0.02 \text{ m})}{6.9 \text{ m}^{-1} \times 0.02 \text{ m}} = 0.994$$

$$\frac{NA_f}{A} = \frac{N2wL_f}{(\delta + t)Nw} = \frac{2L_f}{\delta + t} = \frac{2 \times 0.02 \text{ m}}{0.004 \text{ m}} = 10.0$$

$$\frac{A_t}{A} = \frac{NA_f}{A} + \frac{A_b}{A} = \frac{NA_f}{A} + \frac{\delta Nw}{(\delta + t)Nw} = \frac{NA_f}{A} + \frac{\delta}{\delta + t} = 10. + \frac{0.002 \text{ m}}{0.004 \text{ m}} = 10.5$$

$$\tilde{A} = 10.5 - 10.(1 - 0.994) = 10.4$$

$$h_2\tilde{A} = 12 \text{ W/m}^2 \cdot \text{K} \times 10.4 = 125 \text{ W/m}^2 \cdot \text{K}$$

$$\frac{k}{2L} = \frac{25 \text{ W/m} \cdot \text{K}}{0.06 \text{ m}} = 417 \text{ W/m}^2 \cdot \text{K}$$

Thus

$$T_{s,1} = \frac{\left((417 + 125) \text{ W/m}^2 \cdot \text{K} \times 50 \text{ W/m}^2 \cdot \text{K} \times 30^\circ\text{C} \right. \\ \left. + 417 \text{ W/m}^2 \cdot \text{K} \times 125 \text{ W/m}^2 \cdot \text{K} \times 15^\circ\text{C} \right. \\ \left. + (2 \times 417 + 125) \text{ W/m}^2 \cdot \text{K} \times 2 \times 10^5 \text{ W/m}^3 \times 0.03 \text{ m} \right)}{\left(417 \times 50 \right. \\ \left. + 50 \times 125 \right. \\ \left. + 417 \times 125 \right) (\text{W/m}^2 \cdot \text{K})^2}$$

Continued...

PROBLEM 3.142 (Cont.)

$$T_{s,1} = 92.7^\circ\text{C}$$

Similarly,

$$T_{s,2} = 85.8^\circ\text{C}$$

The location of the maximum temperature in the wall can be found by setting the gradient of the temperature (from Equation (1)) to zero:

$$\frac{dT}{dx} = -\frac{\dot{q}x}{k} + \frac{T_{s,2} - T_{s,1}}{2L} = 0$$

Thus, $x_{\max} = k \frac{T_{s,2} - T_{s,1}}{2L\dot{q}}$. Substituting this back into the temperature distribution,

$$\begin{aligned} T_{\max} &= \frac{\dot{q}L^2}{2k} + \frac{k(T_{s,2} - T_{s,1})^2}{8L^2\dot{q}} + \frac{T_{s,1} + T_{s,2}}{2} \\ &= \frac{2 \times 10^5 \text{ W/m}^3 \times (0.03 \text{ m})^2}{2 \times 25 \text{ W/m} \cdot \text{K}} + \frac{25 \text{ W/m} \cdot \text{K} (85.8^\circ\text{C} - 92.7^\circ\text{C})^2}{8 \times (0.03 \text{ m})^2 \times 2 \times 10^5 \text{ W/m}^3} \\ &\quad + \frac{92.7^\circ\text{C} + 85.8^\circ\text{C}}{2} = 93.7^\circ\text{C} \end{aligned} \quad <$$

PROBLEM 3.143

KNOWN: Dimensions, base temperature and environmental conditions associated with a triangular, aluminum fin.

FIND: (a) Fin efficiency and effectiveness, (b) Heat dissipation per unit width.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation and base contact resistance, (5) Uniform convection coefficient.

PROPERTIES: Table A-1, Aluminum, pure ($T \approx 400$ K): $k = 240$ W/m·K.

ANALYSIS: (a) With $L_c = L = 0.006$ m, find

$$A_p = Lt/2 = (0.006 \text{ m})(0.002 \text{ m})/2 = 6 \times 10^{-6} \text{ m}^2,$$

$$L_c^{3/2} (h/kA_p)^{1/2} = (0.006 \text{ m})^{3/2} \left(\frac{40 \text{ W/m}^2 \cdot \text{K}}{240 \text{ W/m} \cdot \text{K} \times 6 \times 10^{-6} \text{ m}^2} \right)^{1/2} = 0.077$$

and from Fig. 3.18, the fin efficiency is

$$\eta_f \approx 0.99.$$

From Eq. 3.86 and Table 3.5, the fin heat rate is

$$q_f = \eta_f q_{\max} = \eta_f h A_{f(\text{tri})} \theta_b = 2\eta_f h w \left[L^2 + (t/2)^2 \right]^{1/2} \theta_b.$$

From Eq. 3.81, the fin effectiveness is

$$\varepsilon_f = \frac{q_f}{h A_{c,b} \theta_b} = \frac{2\eta_f h w \left[L^2 + (t/2)^2 \right]^{1/2} \theta_b}{h (w \cdot t) \theta_b} = \frac{2\eta_f \left[L^2 + (t/2)^2 \right]^{1/2}}{t}$$

$$\varepsilon_f = \frac{2 \times 0.99 \left[(0.006)^2 + (0.002/2)^2 \right]^{1/2} \text{ m}}{0.002 \text{ m}} = 6.02$$

(b) The heat dissipation per unit width is

$$q'_f = (q_f/w) = 2\eta_f h \left[L^2 + (t/2)^2 \right]^{1/2} \theta_b$$

$$q'_f = 2 \times 0.99 \times 40 \text{ W/m}^2 \cdot \text{K} \left[(0.006)^2 + (0.002/2)^2 \right]^{1/2} \text{ m} \times (250 - 20)^\circ \text{C} = 110.8 \text{ W/m}.$$

COMMENTS: The parabolic profile is known to provide the maximum heat dissipation per unit fin mass.

PROBLEM 3.144

KNOWN: Dimensions and base temperature of an annular, aluminum fin of rectangular profile. Ambient air conditions.

FIND: (a) Fin heat loss; (b) Heat loss per unit length of tube with 200 fins spaced at 5 mm increments.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation and contact resistance, (5) Uniform convection coefficient.

PROPERTIES: Table A-1, Aluminum, pure ($T \approx 400$ K): $k = 240$ W/m·K.

ANALYSIS: (a) The fin parameters for use with Figure 3.19 are

$$r_{2c} = r_2 + t/2 = (12.5 \text{ mm} + 10 \text{ mm}) + 0.5 \text{ mm} = 23 \text{ mm} = 0.023 \text{ m}$$

$$r_{2c}/r_1 = 1.84 \quad L_c = L + t/2 = 10.5 \text{ mm} = 0.0105 \text{ m}$$

$$A_p = L_c t = 0.0105 \text{ m} \times 0.001 \text{ m} = 1.05 \times 10^{-5} \text{ m}^2$$

$$L_c^{3/2} \left(\frac{h}{kA_p} \right)^{1/2} = (0.0105 \text{ m})^{3/2} \left(\frac{25 \text{ W/m}^2 \cdot \text{K}}{240 \text{ W/m} \cdot \text{K} \times 1.05 \times 10^{-5} \text{ m}^2} \right)^{1/2} = 0.15$$

Hence, the fin effectiveness is $\eta_f \approx 0.97$, and from Eq. 3.86 and Fig. 3.5, the fin heat rate is

$$q_f = \eta_f q_{\max} = \eta_f h A_{f(\text{ann})} \theta_b = 2\pi \eta_f h \left(r_{2c}^2 - r_1^2 \right) \theta_b$$

$$q_f = 2\pi \times 0.97 \times 25 \text{ W/m}^2 \cdot \text{K} \times \left[(0.023 \text{ m})^2 - (0.0125 \text{ m})^2 \right] 225^\circ \text{C} = 12.8 \text{ W} \quad <$$

(b) Recognizing that there are $N = 200$ fins per meter length of the tube, the total heat rate considering contributions due to the fin and base (unfinned) surfaces is

$$q' = N' q_f + h(1 - N't) 2\pi r_1 \theta_b$$

$$q' = 200 \text{ m}^{-1} \times 12.8 \text{ W} + 25 \text{ W/m}^2 \cdot \text{K} \left(1 - 200 \text{ m}^{-1} \times 0.001 \text{ m} \right) \times 2\pi \times (0.0125 \text{ m}) 225^\circ \text{C}$$

$$q' = (2560 \text{ W} + 353 \text{ W})/\text{m} = 2.91 \text{ kW/m} \quad <$$

COMMENTS: Note that, while covering only 20% of the tube surface area, the tubes account for more than 85% of the total heat dissipation.

PROBLEM 3.145

KNOWN: Dimensions and base temperature of aluminum fins of rectangular profile. Ambient air conditions.

FIND: (a) Fin efficiency and effectiveness, (b) Rate of heat transfer per unit length of tube.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction in fins, (3) Constant properties, (4) Negligible radiation, (5) Negligible base contact resistance, (6) Uniform convection coefficient.

PROPERTIES: Table A-1, Aluminum, pure ($T \approx 400$ K): $k = 240$ W/m·K.

ANALYSIS: (a) The fin parameters for use with Figure 3.19 are

$$\begin{aligned} r_{2c} &= r_2 + t/2 = 40 \text{ mm} + 2 \text{ mm} = 0.042 \text{ m} & L_c &= L + t/2 = 15 \text{ mm} + 2 \text{ mm} = 0.017 \text{ m} \\ r_{2c}/r_1 &= 0.042 \text{ m}/0.025 \text{ m} = 1.68 & A_p &= L_c t = 0.017 \text{ m} \times 0.004 \text{ m} = 6.8 \times 10^{-5} \text{ m}^2 \\ L_c^{3/2} (h/kA_p)^{1/2} &= (0.017 \text{ m})^{3/2} \left[40 \text{ W/m}^2 \cdot \text{K} / 240 \text{ W/m} \cdot \text{K} \times 6.8 \times 10^{-5} \text{ m}^2 \right]^{1/2} = 0.11 \end{aligned}$$

The fin efficiency is $\eta_f \approx 0.97$. From Eq. 3.86,

$$\begin{aligned} q_f &= \eta_f q_{f,\max} = \eta_f h A_{f(\text{ann})} \theta_b = 2\pi \eta_f h \left[r_{2c}^2 - r_1^2 \right] \theta_b \\ q_f &= 2\pi \times 0.97 \times 40 \text{ W/m}^2 \cdot \text{K} \left[(0.042)^2 - (0.025)^2 \right] \text{m}^2 \times 180^\circ \text{C} = 50 \text{ W} \end{aligned} \quad <$$

From Eq. 3.81, the fin effectiveness is

$$\varepsilon_f = \frac{q_f}{h A_{c,b} \theta_b} = \frac{50 \text{ W}}{40 \text{ W/m}^2 \cdot \text{K} \cdot 2\pi (0.025 \text{ m}) (0.004 \text{ m}) 180^\circ \text{C}} = 11.05 \quad <$$

(b) The rate of heat transfer per unit length is

$$\begin{aligned} q' &= N' q_f + h (1 - N' t) (2\pi r_1) \theta_b \\ q' &= 125 \times 50 \text{ W/m} + 40 \text{ W/m}^2 \cdot \text{K} (1 - 125 \times 0.004) (2\pi \times 0.025 \text{ m}) \times 180^\circ \text{C} \\ q' &= (6250 + 565) \text{ W/m} = 6.82 \text{ kW/m} \end{aligned} \quad <$$

COMMENTS: Note the dominant contribution made by the fins to the total heat transfer.

PROBLEM 3.146

KNOWN: Dimensions and materials of a finned (annular) cylinder wall. Heat flux and ambient air conditions. Contact resistance.

FIND: Surface and interface temperatures (a) without and (b) with an interface contact resistance.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Constant properties, (3) Uniform h over surfaces, (4) Negligible radiation.

ANALYSIS: The analysis may be performed per unit length of cylinder or for a 4 mm long section. The following calculations are based on a unit length. The inner surface temperature may be obtained from

$$q' = \frac{T_i - T_\infty}{R'_{\text{tot}}} = q''_i (2\pi r_i) = 10^5 \text{ W/m}^2 \times 2\pi \times 0.06 \text{ m} = 37,700 \text{ W/m}$$

where $R'_{\text{tot}} = R'_c + R'_{t,c} + R'_w + R'_{\text{equiv}}$; $R'_{\text{equiv}} = (1/R'_f + 1/R'_b)^{-1}$.

R'_c , Conduction resistance of cylinder wall:

$$R'_c = \frac{\ln(r_f/r_i)}{2\pi k} = \frac{\ln(66/60)}{2\pi (50 \text{ W/m}\cdot\text{K})} = 3.034 \times 10^{-4} \text{ m}\cdot\text{K/W}$$

$R'_{t,c}$, Contact resistance:

$$R'_{t,c} = R''_{t,c} / 2\pi r_f = 10^{-4} \text{ m}^2 \cdot \text{K/W} / 2\pi \times 0.066 \text{ m} = 2.411 \times 10^{-4} \text{ m}\cdot\text{K/W}$$

R'_w , Conduction resistance of aluminum base:

$$R'_w = \frac{\ln(r_b/r_f)}{2\pi k} = \frac{\ln(70/66)}{2\pi \times 240 \text{ W/m}\cdot\text{K}} = 3.902 \times 10^{-5} \text{ m}\cdot\text{K/W}$$

R'_b , Resistance of prime or unfinned surface:

$$R'_b = \frac{1}{hA_b} = \frac{1}{100 \text{ W/m}^2 \cdot \text{K} \times 0.5 \times 2\pi (0.07 \text{ m})} = 454.7 \times 10^{-4} \text{ m}\cdot\text{K/W}$$

R'_f , Resistance of fins: The fin resistance may be determined from

$$R'_f = \frac{T_b - T_\infty}{q'_f} = \frac{1}{\eta_f h A'_f}$$

The fin efficiency may be obtained from Fig. 3.19,

$$r_{2c} = r_o + t/2 = 0.096 \text{ m} \quad L_c = L + t/2 = 0.026 \text{ m}$$

Continued

PROBLEM 3.146 (Cont.)

$$A_p = L_c t = 5.2 \times 10^{-5} \text{ m}^2 \quad r_{2c} / \eta = 1.45 \quad L_c^{3/2} (h/kA_p)^{1/2} = 0.375$$

Fig. 3.19 $\rightarrow \eta_f \approx 0.88$.

The total fin surface area per meter length

$$A_f' = 250 \left[\pi (r_o^2 - r_b^2) \times 2 \right] = 250 \text{ m}^{-1} \left[2\pi (0.096^2 - 0.07^2) \right] \text{ m}^2 = 6.78 \text{ m}.$$

Hence
$$R_f' = \left[0.88 \times 100 \text{ W/m}^2 \cdot \text{K} \times 6.78 \text{ m} \right]^{-1} = 16.8 \times 10^{-4} \text{ m} \cdot \text{K/W}$$

$$1/R'_{\text{equiv}} = \left(1/16.8 \times 10^{-4} + 1/454.7 \times 10^{-4} \right) \text{ W/m} \cdot \text{K} = 617.2 \text{ W/m} \cdot \text{K}$$

$$R'_{\text{equiv}} = 16.2 \times 10^{-4} \text{ m} \cdot \text{K/W}.$$

Neglecting the *contact resistance*,

$$R'_{\text{tot}} = (3.034 + 0.390 + 16.2) 10^{-4} \text{ m} \cdot \text{K/W} = 19.6 \times 10^{-4} \text{ m} \cdot \text{K/W}$$

$$T_j = q'R'_{\text{tot}} + T_\infty = 37,700 \text{ W/m} \times 19.6 \times 10^{-4} \text{ m} \cdot \text{K/W} + 320 \text{ K} = 393.9 \text{ K} \quad <$$

$$T_l = T_j - q'R'_w = 393.9 \text{ K} - 37,700 \text{ W/m} \times 3.034 \times 10^{-4} \text{ m} \cdot \text{K/W} = 382.5 \text{ K} \quad <$$

$$T_b = T_l - q'R'_b = 382.5 \text{ K} - 37,700 \text{ W/m} \times 3.902 \times 10^{-5} \text{ m} \cdot \text{K/W} = 381.0 \text{ K}. \quad <$$

Including the *contact resistance*,

$$R'_{\text{tot}} = \left(19.6 \times 10^{-4} + 2.411 \times 10^{-4} \right) \text{ m} \cdot \text{K/W} = 22.0 \times 10^{-4} \text{ m} \cdot \text{K/W}$$

$$T_j = 37,700 \text{ W/m} \times 22.0 \times 10^{-4} \text{ m} \cdot \text{K/W} + 320 \text{ K} = 402.9 \text{ K} \quad <$$

$$T_{l,i} = 402.9 \text{ K} - 37,700 \text{ W/m} \times 3.034 \times 10^{-4} \text{ m} \cdot \text{K/W} = 391.5 \text{ K} \quad <$$

$$T_{l,o} = 391.5 \text{ K} - 37,700 \text{ W/m} \times 2.411 \times 10^{-4} \text{ m} \cdot \text{K/W} = 382.4 \text{ K} \quad <$$

$$T_b = 382.4 \text{ K} - 37,700 \text{ W/m} \times 3.902 \times 10^{-5} \text{ m} \cdot \text{K/W} = 380.9 \text{ K}. \quad <$$

COMMENTS: (1) The effect of the contact resistance is small.

(2) The effect of including the aluminum fins may be determined by computing T_j without the fins. In this case $R'_{\text{tot}} = R'_c + R'_{\text{conv}}$, where

$$R'_{\text{conv}} = \frac{1}{h2\pi\eta_l} = \frac{1}{100 \text{ W/m}^2 \cdot \text{K} \ 2\pi(0.066 \text{ m})} = 241.1 \times 10^{-4} \text{ m} \cdot \text{K/W}.$$

Hence, $R'_{\text{tot}} = 244.1 \times 10^{-4} \text{ m} \cdot \text{K/W}$, and

$$T_j = q'R'_{\text{tot}} + T_\infty = 37,700 \text{ W/m} \times 244.1 \times 10^{-4} \text{ m} \cdot \text{K/W} + 320 \text{ K} = 1240 \text{ K}.$$

Hence, the fins have a significant effect on reducing the cylinder temperature.

(3) The overall surface efficiency is

$$\eta_o = 1 - (A_f' / A_l') (1 - \eta_f) = 1 - 6.78 \text{ m} / 7.00 \text{ m} (1 - 0.88) = 0.884.$$

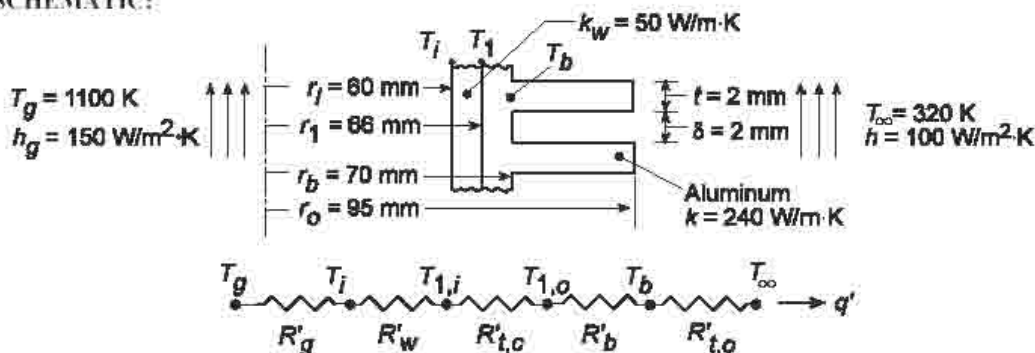

It follows that $q' = \eta_o h_o A_l' \theta_b = 37,700 \text{ W/m}$, which agrees with the prescribed value.

PROBLEM 3.147

KNOWN: Dimensions and materials of a finned (annular) cylinder wall. Combustion gas and ambient air conditions. Contact resistance.

FIND: (a) Heat rate per unit length and surface and interface temperatures, (b) Effect of increasing the fin thickness.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Constant properties, (3) Uniform h over surfaces, (4) Negligible radiation.

ANALYSIS: (a) The heat rate per unit length is

$$q' = \frac{T_g - T_\infty}{R'_{\text{tot}}}$$

where $R'_{\text{tot}} = R'_g + R'_w + R'_{t,c} + R'_b + R'_{t,o}$; and

$$R'_g = \left(h_g 2\pi r_i \right)^{-1} = \left(150 \text{ W/m}^2 \cdot \text{K} \times 2\pi \times 0.06 \text{ m} \right)^{-1} = 0.0177 \text{ m} \cdot \text{K/W}$$

$$R'_w = \frac{\ln(r_1/r_i)}{2\pi k_w} = \frac{\ln(66/60)}{2\pi (50 \text{ W/m} \cdot \text{K})} = 3.03 \times 10^{-4} \text{ m} \cdot \text{K/W}$$

$$R'_{t,c} = \left(R'_{t,c} / 2\pi r_1 \right) = 10^{-4} \text{ m}^2 \cdot \text{K/W} / 2\pi \times 0.066 \text{ m} = 2.41 \times 10^{-4} \text{ m} \cdot \text{K/W}$$

$$R'_b = \frac{\ln(r_b/r_1)}{2\pi k} = \frac{\ln(70/66)}{2\pi \times 240 \text{ W/m} \cdot \text{K}} = 3.90 \times 10^{-5} \text{ m} \cdot \text{K/W}$$

$$R'_{t,o} = \left(\eta_o h A'_f \right)^{-1}$$

$$\eta_o = 1 - \frac{N' A_f}{A'_t} (1 - \eta_f)$$

$$A_f = 2\pi (r_{oc}^2 - r_b^2)$$

$$A'_t = N' A_f + (1 - N') 2\pi r_b$$

$$\eta_f = \frac{(2r_b/m) K_1(mr_b) I_1(mr_{oc}) - I_1(mr_b) K_1(mr_{oc})}{\left(r_{oc}^2 - r_b^2 \right) I_0(mr_b) K_1(mr_{oc}) + K_0(mr_b) I_1(mr_{oc})}$$

$$r_{oc} = r_o + (t/2), \quad m = (2h/kt)^{1/2}$$

Continued...

PROBLEM 3.147 (Cont.)

Once the heat rate is determined from the foregoing expressions, the desired interface temperatures may be obtained from

$$T_i = T_g - q'R'_g$$

$$T_{l,i} = T_g - q'(R'_g + R'_w)$$

$$T_{l,o} = T_g - q'(R'_g + R'_w + R'_{t,c})$$

$$T_b = T_g - q'(R'_g + R'_w + R'_{t,c} + R'_b)$$

For the specified conditions we obtain $A'_t = 7.00 \text{ m}$, $\eta_f = 0.902$, $\eta_o = 0.906$ and $R'_{t,o} = 0.00158 \text{ m}\cdot\text{K}/\text{W}$. It follows that

$$q' = 39,300 \text{ W/m} \quad <$$

$$T_i = 405\text{K}, \quad T_{l,i} = 393\text{K}, \quad T_{l,o} = 384\text{K}, \quad T_b = 382\text{K} \quad <$$

(b) The *Performance Calculation, Extended Surface* Model for the *Circular Fin* Array may be used to assess the effects of fin thickness and spacing. Increasing the fin thickness to $t = 3 \text{ mm}$, with $\delta = 2 \text{ mm}$, reduces the number of fins per unit length to 200. Hence, although the fin efficiency increases ($\eta_f = 0.930$), the reduction in the total surface area ($A'_t = 5.72 \text{ m}$) yields an increase in the resistance of the fin array ($R'_{t,o} = 0.00188 \text{ m}\cdot\text{K}/\text{W}$), and hence a reduction in the heat rate ($q' = 38,700 \text{ W/m}$) and an increase in the interface temperatures ($T_i = 415 \text{ K}$, $T_{l,i} = 404 \text{ K}$, $T_{l,o} = 394 \text{ K}$, and $T_b = 393 \text{ K}$).

COMMENTS: Because the gas convection resistance exceeds all other resistances by at least an order of magnitude, incremental changes in $R'_{t,o}$ will not have a significant effect on q' or the interface temperatures.

PROBLEM 3.148

KNOWN: Dimensions of finned aluminum sleeve inserted over a transistor. Contact resistance between sleeve and transistor. Surface convection conditions and temperature of transistor case.

FIND: (a) Rate of heat transfer from sleeve and (b) Measures for increasing heat dissipation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer from the top and bottom surfaces of the transistor, (3) One-dimensional radial conduction, (4) Constant properties, (5) Negligible radiation.

ANALYSIS:

(a) The circuit must account for the contact resistance, conduction in the sleeve, convection from the exposed base, and conduction/convection from the fins.

Thermal resistances for the contact joint and sleeve are

$$R_{t,c} = \frac{R_{t,c}''}{2\pi r_1 H} = \frac{0.6 \times 10^{-3} \text{ m}^2 \cdot \text{K/W}}{2\pi(0.0025 \text{ m})(0.004 \text{ m})} = 9.55 \text{ K/W}$$

$$R_{t,\text{sleeve}} = \frac{\ln(r_2/r_1)}{2\pi k H} = \frac{\ln(3.5/2.5)}{2\pi(200 \text{ W/m} \cdot \text{K})(0.004 \text{ m})} = 0.0669 \text{ K/W}$$

For a single fin, $R_{t,f} = \theta_b / q_f$, where from Table 3.4, with tip convection,

Continued...

PROBLEM 3.148 (Cont.)

$$q_f = (hPkA_c)^{1/2} \theta_b \frac{\sinh(mL) + (h/mk)\cosh(mL)}{\cosh(mL) + (h/mk)\sinh(mL)}$$

with $P = 2(H + t) = 9.6 \text{ mm} = 0.0096 \text{ m}$ and $A_c = t \times H = 3.2 \times 10^{-6} \text{ m}^2$,

$$m = \left(\frac{hP}{kA_c} \right)^{1/2} = \left(\frac{30 \text{ W/m}^2 \cdot \text{K} \times 0.0096 \text{ m}}{200 \text{ W/m} \cdot \text{K} \times 3.2 \times 10^{-6} \text{ m}^2} \right)^{1/2} = 21.2 \text{ m}^{-1}$$

$$mL = 21.2 \text{ m}^{-1} \times 0.008 \text{ m} = 0.170$$

$$\frac{h}{mk} = \frac{30 \text{ W/m}^2 \cdot \text{K}}{21.2 \text{ m}^{-1} \times 200 \text{ W/m} \cdot \text{K}} = 0.00707$$

and

$$(hPkA_c)^{1/2} = (30 \text{ W/m}^2 \cdot \text{K} \times 0.0096 \text{ m} \times 200 \text{ W/m} \cdot \text{K} \times 3.2 \times 10^{-6} \text{ m}^2)^{1/2} = 0.0136 \text{ W/K}$$

Use of Table B.1 yields, for a single fin

$$R_{t,f} = \frac{1.014 + 0.00707 \times 0.171}{0.0136 \text{ W/K} (0.171 + 0.00707 \times 1.014)} = 421 \text{ K/W}$$

Hence, for 12 fins,

$$R_{t,f(12)} = \frac{R_{t,f}}{12} = 35.1 \text{ K/W}$$

For the exposed base,

$$R_{t,b} = \frac{1}{h(2\pi r_2 - 12t)H} = \frac{1}{30 \text{ W/m}^2 \cdot \text{K} (2\pi \times 0.0035 - 12 \times 0.0008) \text{ m} \times 0.004 \text{ m}} = 673 \text{ K/W}$$

With

$$R_{t,o} = \left[(35.1)^{-1} + (673)^{-1} \right]^{-1} = 33.3 \text{ K/W}$$

it follows that

$$R_{\text{tot}} = (9.55 + 0.0669 + 33.3) \text{ K/W} = 43.0 \text{ K/W}$$

and

$$q_t = \frac{T_1 - T_\infty}{R_{\text{tot}}} = \frac{(80 - 20)^\circ\text{C}}{43.0 \text{ K/W}} = 1.40 \text{ W} \quad <$$

(b) With $2\pi r_2 = 0.022 \text{ m}$ and $Nt = 0.0096 \text{ m}$, the existing gap between fins is extremely small (0.96 mm). Hence, by increasing N and/or t , it would become even more difficult to maintain satisfactory airflow between the fins, and this option is not particularly attractive.

Because the fin efficiency for the prescribed conditions is close to unity ($\eta_f = (hA_f R_{t,f})^{-1} = 0.992$), there is little advantage to replacing the aluminum with a material of higher thermal conductivity (e.g. Cu

Continued...

PROBLEM 3.148 (Cont.)

with $k \sim 400 \text{ W/m}\cdot\text{K}$). However, the large value of η_f suggests that significant benefit could be gained by increasing the fin length, $L = r_3 - r_2$.

It is also evident that the thermal contact resistance is large, and from Table 3.2, it's clear that a significant reduction could be effected by using indium foil or a conducting grease in the contact zone. Specifically, a reduction of $R''_{t,c}$ from 0.6×10^{-3} to 10^{-4} or even $10^{-5} \text{ m}^2\cdot\text{K/W}$ is certainly feasible.

Table 1.1 suggests that, by increasing the velocity of air flowing over the fins, a larger convection coefficient may be achieved. A value of $h = 100 \text{ W/m}^2\cdot\text{K}$ would not be unreasonable.

As options for enhancing heat transfer, we therefore enter the foregoing equations into IHT to explore the effect of parameter variations over the ranges $8 \leq L \leq 20 \text{ mm}$, $10^{-5} \leq R''_{t,c} \leq 0.6 \times 10^{-3} \text{ m}^2\cdot\text{K/W}$ and $30 \leq h \leq 100 \text{ W/m}^2\cdot\text{K}$. As shown below, there is a significant enhancement in heat transfer associated with reducing $R''_{t,c}$ from 0.6×10^{-3} to $10^{-4} \text{ m}^2\cdot\text{K/W}$, for which $R_{t,c}$ decreases from 9.55 to 1.59 K/W. At this value of $R''_{t,c}$, the reduction in $R_{t,o}$ from 33.3 to 14.8 K/W which accompanies an increase in L from 8 to 20 mm becomes significant, yielding a heat rate of $q_t = 3.65 \text{ W}$ for $R''_{t,c} = 10^{-4} \text{ m}^2\cdot\text{K/W}$ and $L = 20 \text{ mm}$. However, since $R_{t,o} \gg R_{t,c}$, little benefit is gained by further reducing $R''_{t,c}$ to $10^{-5} \text{ m}^2\cdot\text{K/W}$.

To derive benefit from a reduction in $R''_{t,c}$ to $10^{-5} \text{ m}^2\cdot\text{K/W}$, an additional reduction in $R_{t,o}$ must be made. This can be achieved by increasing h , and for $L = 20 \text{ mm}$ and $h = 100 \text{ W/m}^2\cdot\text{K}$, $R_{t,o} = 5.0 \text{ K/W}$. With $R''_{t,c} = 10^{-5} \text{ m}^2\cdot\text{K/W}$, a value of $q_t = 11.5 \text{ W}$ may be achieved.

Continued...

PROBLEM 3.148 (Cont.)

COMMENTS: (1) Without the finned sleeve, the convection resistance of the transistor case is $R_{t,can} = (2\pi r_1 H h)^{-1} = 531 \text{ K/W}$. Hence there is considerable advantage to using the fins. (2) If an adiabatic fin tip is assumed, $\tanh(mL) = 0.168$ and $R_{t,f} = 437$. Hence the error in the fin resistance is 4% relative to the actual convecting tip. (3) With $\eta_f = 0.992$, Equation 3.102 yields $\eta_o = 0.992$, from which it follows that $R_{t,o} = (\eta_o h A_t)^{-1} = 33.3 \text{ K/W}$. This result is, of course, identical to that obtained in the foregoing determination of $R_{t,o}$. (4) In assessing options for enhancing heat transfer, the limiting (largest) resistance(s) should be identified and efforts directed at their reduction.

PROBLEM 3.149

KNOWN: Diameter and internal fin configuration of copper tubes submerged in water. Tube wall temperature and temperature and convection coefficient of gas flow through the tube.

FIND: Rate of heat transfer per tube length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional fin conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient, (6) Tube wall may be unfolded and represented as a plane wall with four straight, rectangular fins, each with an adiabatic tip (since, by symmetry, there can be no heat flow along the fins where they cross).

ANALYSIS: The rate of heat transfer per unit tube length is:

$$q'_t = \eta_o h A'_t (T_g - T_s)$$

$$\eta_o = 1 - \frac{NA'_f}{A'_t} (1 - \eta_f)$$

$$NA'_f = 4 \times 2L = 8(0.025\text{ m}) = 0.20\text{ m}$$

$$A'_t = NA'_f + A'_b = 0.20\text{ m} + (\pi D - 4t) = 0.20\text{ m} + (\pi \times 0.05\text{ m} - 4 \times 0.005\text{ m}) = 0.337\text{ m}$$

For an adiabatic fin tip,

$$\eta_f = \frac{q_f}{q_{\max}} = \frac{M \tanh mL}{h(2L)(T_g - T_s)}$$

$$M = [h2(1m + t)k(1m \times t)]^{1/2} (T_g - T_s) \approx [30\text{ W/m}^2 \cdot \text{K}(2\text{ m})400\text{ W/m} \cdot \text{K}(0.005\text{ m}^2)]^{1/2} (400\text{ K}) = 4382\text{ W}$$

$$mL = \left\{ \frac{h2(1m + t)}{k(1m \times t)} \right\}^{1/2} L \approx \left[\frac{30\text{ W/m}^2 \cdot \text{K}(2\text{ m})}{400\text{ W/m} \cdot \text{K}(0.005\text{ m}^2)} \right]^{1/2} 0.025\text{ m} = 0.137$$

Hence, $\tanh mL = 0.136$, and

$$\eta_f = \frac{4382\text{ W}(0.136)}{30\text{ W/m}^2 \cdot \text{K}(0.05\text{ m}^2)(400\text{ K})} = \frac{595\text{ W}}{600\text{ W}} = 0.992$$

$$\eta_o = 1 - \frac{0.20}{0.337} (1 - 0.992) = 0.995$$

$$q'_t = 0.995(30\text{ W/m}^2 \cdot \text{K})0.337\text{ m}(400\text{ K}) = 4025\text{ W/m}$$

COMMENTS: Alternatively, $q'_t = 4q'_f + h(A'_t - A'_f)(T_g - T_s)$. Hence, $q' = 4(595\text{ W/m}) + 30\text{ W/m}^2 \cdot \text{K}(0.137\text{ m})(400\text{ K}) = (2380 + 1644)\text{ W/m} = 4024\text{ W/m}$.

PROBLEM 3.150

KNOWN: Internal and external convection conditions for an internally finned tube. Fin/tube dimensions and contact resistance.

FIND: Heat rate per unit tube length and corresponding effects of the contact resistance, number of fins, and fin/tube material.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient on finned surfaces, (6) Tube wall may be unfolded and approximated as a plane surface with N straight rectangular fins.

PROPERTIES: Copper: $k = 400$ W/m-K; St.St.: $k = 20$ W/m-K.

ANALYSIS: The heat rate per unit length may be expressed as

$$q' = \frac{T_g - T_w}{R'_{t,o(c)} + R'_{\text{cond}} + R'_{\text{conv},o}}$$

where

$$R'_{t,o(c)} = (\eta_o(c) h_g A'_t), \quad \eta_o(c) = 1 - \frac{N A'_f}{A'_t} \left(1 - \frac{\eta_f}{C_1} \right), \quad C_1 = 1 + \eta_f h_g A'_f (R''_{t,c} / A'_{c,b}),$$

$$A'_t = N A'_f + (2\pi r_1 - N t), \quad A'_f = 2\eta_1, \quad \eta_f = \tanh m\eta_1 / m\eta_1, \quad m = (2h_g / kt)^{1/2} \quad A'_{c,b} = t,$$

$$R'_{\text{cond}} = \frac{\ln(r_2 / r_1)}{2\pi k}, \quad \text{and} \quad R'_{\text{conv},o} = (2\pi r_2 h_w)^{-1}.$$

Using the IHT *Performance Calculation, Extended Surface Model* for the *Straight Fin Array*, the following results were obtained. For the *base case*, $q' = 3857$ W/m, where $R'_{t,o(c)} = 0.101$ m-K/W, $R'_{\text{cond}} = 7.25 \times 10^{-5}$ m-K/W and $R'_{\text{conv},o} = 0.00265$ m-K/W. If the contact resistance is eliminated ($R''_{t,c} = 0$), $q' = 3922$ W/m, where $R'_{t,o} = 0.0993$ m-K/W. If the number of fins is increased to $N = 8$, $q' = 5799$ W/m, with $R'_{t,o(c)} = 0.063$ m-K/W. If the material is changed to stainless steel, $q' = 3591$ W/m, with $R'_{t,o(c)} = 0.107$ m-K/W and $R'_{\text{cond}} = 0.00145$ m-K/W.

COMMENTS: The small reduction in q' associated with use of stainless steel is perhaps surprising, in view of the large reduction in k . However, because h_g is small, the reduction in k does not significantly reduce the fin efficiency (η_f changes from 0.994 to 0.891). Hence, the heat rate remains large. The influence of k would become more pronounced with increasing h_g .

PROBLEM 3.151

KNOWN: Design and operating conditions of a tubular, air/water heater.

FIND: (a) Expressions for heat rate per unit length at inner and outer surfaces, (b) Expressions for inner and outer surface temperatures, (c) Surface heat rates and temperatures as a function of volumetric heating \dot{q} for prescribed conditions. Upper limit to \dot{q} .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) One-dimensional heat transfer.

PROPERTIES: Table A-1: Aluminum, $T = 300$ K, $k_a = 237$ W/m·K.

ANALYSIS: (a) Applying Equation C.8 to the inner and outer surfaces, it follows that

$$q'(r_i) = \dot{q}\pi r_i^2 - \frac{2\pi k_s}{\ln(r_o/r_i)} \left[\frac{\dot{q}r_o^2}{4k_s} \left(1 - \frac{r_i^2}{r_o^2} \right) + (T_{s,o} - T_{s,i}) \right] \quad <$$

$$q'(r_o) = \dot{q}\pi r_o^2 - \frac{2\pi k_s}{\ln(r_o/r_i)} \left[\frac{\dot{q}r_o^2}{4k_s} \left(1 - \frac{r_i^2}{r_o^2} \right) + (T_{s,o} - T_{s,i}) \right] \quad <$$

(b) From Equations C.16 and C.17, energy balances at the inner and outer surfaces are of the form

$$h_i(T_{\infty,i} - T_{s,i}) = \frac{\dot{q}r_i}{2} - \frac{k_s \left[\frac{\dot{q}r_o^2}{4k_s} \left(1 - \frac{r_i^2}{r_o^2} \right) + (T_{s,o} - T_{s,i}) \right]}{r_i \ln(r_o/r_i)} \quad <$$

$$U_o(T_{s,o} - T_{\infty,o}) = \frac{\dot{q}r_o}{2} - \frac{k_s \left[\frac{\dot{q}r_o^2}{4k_s} \left(1 - \frac{r_i^2}{r_o^2} \right) + (T_{s,o} - T_{s,i}) \right]}{r_o \ln(r_o/r_i)} \quad <$$

Accounting for the fin array and the contact resistance, Equation 3.104 may be used to cast the overall heat transfer coefficient U_o in the form

$$U_o = \frac{q'(r_o)}{A'_w(T_{s,o} - T_{\infty,o})} = \frac{1}{A'_w R'_{t,o(c)}} = \frac{A'_t}{A'_w} \eta_{o(c)} h_o$$

where $\eta_{o(c)}$ is determined from Equations 3.105a,b and $A'_w = 2\pi r_o$.

Continued...

PROBLEM 3.151 (Cont.)

(c) For the prescribed conditions and a representative range of $10^7 \leq \dot{q} \leq 10^8 \text{ W/m}^3$, use of the relations of part (b) with the capabilities of the IHT *Performance Calculation Extended Surface Model* for a *Circular Fin Array* yields the following graphical results.

It is in this range that the upper limit of $T_{s,i} = 373 \text{ K}$ is exceeded for $\dot{q} = 4.9 \times 10^7 \text{ W/m}^3$, while the corresponding value of $T_{s,o} = 379 \text{ K}$ is well below the prescribed upper limit. The expressions of part (a) yield the following results for the surface heat rates, where heat transfer in the negative r direction corresponds to $q'(r_i) < 0$.

For $\dot{q} = 4.9 \times 10^7 \text{ W/m}^3$, $q'(r_i) = -2.30 \times 10^4 \text{ W/m}$ and $q'(r_o) = 1.93 \times 10^4 \text{ W/m}$.

COMMENTS: The foregoing design provides for comparable heat transfer to the air and water streams. This result is a consequence of the nearly equivalent thermal resistances associated with heat transfer from the inner and outer surfaces. Specifically, $R'_{\text{conv},i} = (h_i 2\pi r_i)^{-1} = 0.00318 \text{ m}\cdot\text{K/W}$ is slightly smaller than $R'_{t,o(c)} = 0.00411 \text{ m}\cdot\text{K/W}$, in which case $|q'(r_i)|$ is slightly larger than $q'(r_o)$, while $T_{s,i}$ is slightly smaller than $T_{s,o}$. Note that the solution must satisfy the energy conservation requirement, $\pi(r_o^2 - r_i^2)\dot{q} = |q'(r_i)| + q'(r_o)$.

PROBLEM 3.152

KNOWN: Dimensions and thermal conductivities of a muscle layer and a skin/fat layer. Skin emissivity and surface area. Metabolic heat generation rate and perfusion rate within the muscle layer. Core body and arterial temperatures. Blood density and specific heat. Ambient conditions.

FIND: Perspiration rate to maintain same skin temperature as in Example 3.12.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer through the muscle and skin/fat layers, (3) Metabolic heat generation rate, perfusion rate, arterial temperature, blood properties, and thermal conductivities are all uniform, (4) Radiation heat transfer coefficient is known from Example 1.6, (5) Solar radiation is negligible, (6) Conditions are the same everywhere on the torso, limbs, etc., (7) Perspiration on skin has a negligible effect on heat transfer from the skin to the environment, that is, it adds a negligible thermal resistance and doesn't change the emissivity.

ANALYSIS: First we need to find the skin temperature, T_s , for the conditions of Example 3.12, in the air environment. Both q and T_i , the interface temperature between the muscle and the skin/fat layer, are known. The rate of heat transfer across the skin/fat layer is given by

$$q = \frac{k_{sf} A (T_i - T_s)}{L_{sf}} \quad (1)$$

Thus, the skin temperature is

$$T_s = T_i - \frac{q L_{sf}}{k_{sf} A} = 34.8^\circ\text{C} - \frac{142 \text{ W} \times 0.003 \text{ m}}{0.3 \text{ W/m} \cdot \text{K} \times 1.8 \text{ m}^2} = 34.0^\circ\text{C}$$

Now the heat transfer rate will change because of the increased metabolic heat generation rate. Heat transfer in the muscle layer is governed by Equation 3.109. In Example 3.12, this equation was solved subject to specified temperature boundary conditions, and the rate at which heat leaves the muscle and enters the skin/fat layer was found to be

$$q|_{x=L_m} = -k_m A \tilde{m} \theta_c \frac{(\theta_i/\theta_c) \cosh \tilde{m} L_m - 1}{\sinh \tilde{m} L_m} \quad (2)$$

Continued...

PROBLEM 3.152 (Cont.)

This must equal the rate at which heat is transferred across the skin/fat layer, given by Equation (1). Equating Equations 1 and 2 and solving for T_i , recalling that T_i also appears in θ_i , yields

$$T_i = \frac{T_s \sinh \tilde{m} L_m + k_m \tilde{m} \frac{L_{sf}}{k_{sf}} \left[\theta_c + \left(T_a + \frac{\dot{q}_m}{\omega \rho_b c_b} \right) \cosh \tilde{m} L_m \right]}{\sinh \tilde{m} L_m + k_m \tilde{m} \frac{L_{sf}}{k_{sf}} \cosh \tilde{m} L_m}$$

where

$$\tilde{m} = \sqrt{\omega \rho_b c_b / k_m} = \left[0.0005 \text{ s}^{-1} \times 1000 \text{ kg/m}^3 \times 3600 \text{ J/kg} \cdot \text{K} / 0.5 \text{ W/m} \cdot \text{K} \right]^{1/2} = 60 \text{ m}^{-1}$$

$$\sinh(\tilde{m} L_m) = \sinh(60 \text{ m}^{-1} \times 0.03 \text{ m}) = 2.94; \quad \cosh(\tilde{m} L_m) = \cosh(60 \text{ m}^{-1} \times 0.03 \text{ m}) = 3.11$$

$$\theta_c = T_c - T_a - \frac{\dot{q}_m}{\omega \rho_b c_b} = - \frac{\dot{q}_m}{\omega \rho_b c_b} = - \frac{5600 \text{ W/m}^3}{0.0005 \text{ s}^{-1} \times 1000 \text{ kg/m}^3 \times 3600 \text{ J/kg} \cdot \text{K}} = -3.11 \text{ K}$$

The excess temperature can be expressed in kelvins or degrees Celsius, since it is a temperature difference. Thus

$$T_i = \frac{34.0^\circ\text{C} \times 2.94 + 0.5 \text{ W/m} \cdot \text{K} \times 60 \text{ m}^{-1} \times \frac{0.003 \text{ m}}{0.3 \text{ W/m} \cdot \text{K}} [-3.11^\circ\text{C} + (37^\circ\text{C} + 3.11^\circ\text{C}) \times 3.11]}{2.94 + 0.5 \text{ W/m} \cdot \text{K} \times 60 \text{ m}^{-1} \times \frac{0.003 \text{ m}}{0.3 \text{ W/m} \cdot \text{K}} \times 3.11}$$

$$T_i = 35.2^\circ\text{C}$$

and again from Equation (1)

$$q = \frac{k_{sf} A (T_i - T_s)}{L_{sf}} = \frac{0.3 \text{ W/m} \cdot \text{K} \times 1.8 \text{ m}^2 (35.2^\circ\text{C} - 34.0^\circ\text{C})}{0.003 \text{ m}} = 222 \text{ W}$$

Since the skin temperature is unchanged from Example 3.12, the rate of heat transfer to the environment by convection and radiation will remain the same, and is therefore still 142 W. The difference of 80 W must be removed from the skin by perspiration, therefore

$$\dot{q}_{\text{per}} = \dot{m}_{\text{per}} h_{fg} = 80 \text{ W}$$

Assuming the properties of perspiration are the same as that of water, evaluated at the skin temperature of 307 K, then from Table A.6 $h_{fg} = 2421 \text{ kJ/kg}$ and $\rho = 994 \text{ kg/m}^3$. Thus the volume rate of perspiration is

$$\dot{V} = \frac{\dot{m}_{\text{per}}}{\rho} = \frac{\dot{q}_{\text{per}}}{\rho h_{fg}} = \frac{80 \text{ W}}{994 \text{ kg/m}^3 \times 2421 \times 10^3 \text{ J/kg}} = 3.3 \times 10^{-8} \text{ m}^3/\text{s} = 3.3 \times 10^{-5} \text{ l/s} <$$

COMMENTS: (1) This is a moderate rate of perspiration. In one hour, it would account for around 0.1 l. (2) In reality, our bodies adjust in many ways to maintain core and skin temperatures. Exercise will likely cause an increase in perfusion rate near the skin surface, to locally elevate the temperature and increase the rate of heat transfer to the environment.

PROBLEM 3.153

KNOWN: Dimensions and thermal conductivities of a muscle layer and a skin/fat layer. Skin emissivity and surface area. Skin temperature. Perfusion rate within the muscle layer. Core body and arterial temperatures. Blood density and specific heat. Ambient conditions.

FIND: Metabolic heat generation rate to maintain skin temperature at 33°C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer through the muscle and skin/fat layers, (3) Metabolic heat generation rate, perfusion rate, arterial temperature, blood properties, and thermal conductivities are all uniform, (4) Solar radiation is negligible, (5) Conditions are the same everywhere on the torso, limbs, etc.

ANALYSIS: Since we know the skin temperature and environment temperature, we can find the heat loss rate from the skin surface to the environment:

$$\begin{aligned} q &= hA(T_s - T_\infty) + \epsilon\sigma A(T_s^4 - T_{\text{sur}}^4) \\ &= 2 \text{ W/m}^2 \cdot \text{K} \times 1.8 \text{ m}^2 (33 - 15)^\circ\text{C} + 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 1.8 \text{ m}^2 (306^4 - 288^4) \text{ K}^4 \\ &= 248 \text{ W} \end{aligned}$$

We can then find T_i , the interface temperature between the skin/fat layer and the muscle layer, by analyzing heat transfer through the skin/fat layer:

$$T_i = T_s + \frac{qL_{\text{sf}}}{k_{\text{sf}}A} = 33^\circ\text{C} + \frac{248 \text{ W} \times 0.003 \text{ m}}{0.3 \text{ W/m} \cdot \text{K} \times 1.8 \text{ m}^2} = 34.4^\circ\text{C}$$

Heat transfer in the muscle layer is governed by Equation 3.109. In Example 3.12, this equation was solved subject to specified surface temperature boundary conditions, and the rate at which heat leaves the muscle and enters the skin/fat layer was found to be

Continued...

PROBLEM 3.153 (Cont.)

$$q = -k_m A \tilde{m} \frac{\theta_i \cosh \tilde{m} L_m - \theta_e}{\sinh \tilde{m} L_m}$$

This must equal the rate at which heat is transferred across the skin/fat layer, as calculated above. Inserting the definitions of θ_i and θ_e , we can solve for the metabolic heat generation rate:

$$\dot{q}_m = \omega \rho_b c_b \frac{\frac{q}{k_m A \tilde{m}} \sinh \tilde{m} L_m + (T_i - T_a) \cosh \tilde{m} L_m + (T_e - T_a)}{\cosh \tilde{m} L_m + 1} \quad (1)$$

where

$$\tilde{m} = \sqrt{\omega \rho_b c_b / k_m} = \left[0.0005 \text{ s}^{-1} \times 1000 \text{ kg/m}^3 \times 3600 \text{ J/kg} \cdot \text{K} / 0.5 \text{ W/m} \cdot \text{K} \right]^{1/2} = 60 \text{ m}^{-1}$$

$$\sinh(\tilde{m} L_m) = \sinh(60 \text{ m}^{-1} \times 0.03 \text{ m}) = 2.94 ; \quad \cosh(\tilde{m} L_m) = \cosh(60 \text{ m}^{-1} \times 0.03 \text{ m}) = 3.11$$

With $T_e = T_a$, Equation (1) yields

$$\begin{aligned} \dot{q}_m &= 0.0005 \text{ s}^{-1} \times 1000 \text{ kg/m}^3 \times 3600 \text{ J/kg} \cdot \text{K} \\ &\times \left[\frac{\frac{248 \text{ W}}{0.5 \text{ W/m} \cdot \text{K} \times 1.8 \text{ m}^2 \times 60 \text{ m}^{-1}} \times 2.94 + (34.4 - 37)^\circ\text{C} \times 3.11}{3.11 + 1} \right] \\ &= 2341 \text{ W/m}^3 \end{aligned} \quad <$$

COMMENT: (1) Shivering can increase the metabolic heat generation rate by up to five to six times the resting metabolic rate. The value found here is approximately three times the metabolic heat generation rate given in Example 3.12, so it is well within what can be produced by shivering. (2) In the water environment, even with the original 24°C water temperature, shivering would be insufficient to maintain a comfortable skin temperature.

PROBLEM 3.154

KNOWN: Dimensions and thermal conductivities of a muscle layer and a skin/fat layer. Metabolic heat generation rate and perfusion rate within the muscle layer. Arterial temperature. Blood density and specific heat. Ambient conditions.

FIND: Heat loss rate from body and temperature at inner surface of the skin/fat layer.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions. (2) One-dimensional heat transfer through the muscle and skin/fat layers. (3) Metabolic heat generation rate, perfusion rate, arterial temperature, blood properties, and thermal conductivities are all uniform. (4) Radiation heat transfer coefficient is known from Example 1.6.

ANALYSIS:

(a) Conduction with heat generation is expressed in radial coordinates by Equation 3.49. With metabolic heat generation and perfusion, this becomes

$$\frac{1}{r} \frac{d}{dr} \left(r \frac{dT}{dr} \right) + \frac{\dot{q}_m + \omega \rho_b c_b (T_a - T)}{k} = 0 \quad <$$

The boundary conditions of symmetry at the centerline and specified temperature at the outer surface of the muscle are expressed as

$$\left. \frac{dT}{dr} \right|_{r=0} = 0, \quad T(r_1) = T_i \quad <$$

Defining an excess temperature, $\theta \equiv T - T_a - \dot{q}_m / \omega \rho_b c_b$, the differential equation becomes

$$\frac{1}{r} \frac{d}{dr} \left(r \frac{d\theta}{dr} \right) - m^2 \theta = 0$$

Continued...

PROBLEM 3.154 (Cont.)

where $\tilde{m}^2 = \omega \rho_b c_b / k$. The general solution to the differential equation is given in Section 3.6.4 as

$$\theta = c_1 I_0(\tilde{m}r) + c_2 K_0(\tilde{m}r)$$

Applying the boundary condition at $r = 0$ yields

$$\left. \frac{dT}{dr} \right|_{r=0} = \left. \frac{d\theta}{dr} \right|_{r=0} = c_1 \tilde{m} I_1(0) - c_2 \tilde{m} K_1(0) = 0$$

Since $K_1(0)$ is infinite, we must have $c_2 = 0$. Applying the specified temperature boundary condition at $r = r_1$ yields

$$T(r_1) = T_1, \quad \theta(r_1) = T_1 - T_a = \frac{\dot{q}_m}{\omega \rho_b c_b} \equiv \theta_1 = c_1 I_0(\tilde{m}r_1)$$

Solving for c_1 we now have the complete solution for θ .

$$\theta = \theta_1 \frac{I_0(\tilde{m}r)}{I_0(\tilde{m}r_1)} \quad (1)$$

(b) The heat flux at the outer surface of the muscle is given by

$$q''_1 = -k_m \left. \frac{dT}{dr} \right|_{r=r_1} = -k_m \left. \frac{d\theta}{dr} \right|_{r=r_1} = -k_m \theta_1 \tilde{m} \frac{I_1(\tilde{m}r_1)}{I_0(\tilde{m}r_1)} \quad (2)$$

This must be equated to the heat flux through the skin/fat layer and into the environment. In terms of the heat transfer rate per unit length of forearm, q''_1 , and the total resistance for a unit length, R'_{tot} ,

$$q''_1 = \frac{\dot{q}_1}{2\pi r_1} = \frac{1}{2\pi r_1} \frac{T_1 - T_\infty}{R'_{\text{tot}}} \quad (3)$$

As in Example 3.1 and for exposure of the skin to the air, R'_{tot} accounts for conduction through the skin/fat layer in series with heat transfer by convection and radiation, which act in parallel with each other. Here the conduction resistance is for a radial geometry. Thus, it is

$$R'_{\text{tot}} = \frac{\ln(r_2/r_1)}{2\pi k_{sf}} + \frac{1}{2\pi r_2} \left(\frac{1}{1/h} + \frac{1}{1/h_r} \right)^{-1} = \frac{\ln(r_2/r_1)}{2\pi k_{sf}} + \frac{1}{2\pi r_2} \left(\frac{1}{h + h_r} \right)$$

Using the values from Example 1.6 for air,

$$R'_{\text{tot}} = \frac{\ln(0.053 \text{ m}/0.05 \text{ m})}{2 \times \pi \times 0.3 \text{ W/m} \cdot \text{K}} + \frac{1}{2 \times \pi \times 0.053 \text{ m}} \left(\frac{1}{(2 + 5.9) \text{ W/m}^2 \cdot \text{K}} \right) = 0.41 \text{ m} \cdot \text{K/W}$$

Combining Equations 2 and 3 yields

Continued...

PROBLEM 3.154 (Cont.)

$$-k_m \theta_i \tilde{m} \frac{I_1(\tilde{m}r_1)}{I_0(\tilde{m}r_1)} = \frac{1}{2\pi r_1} \frac{T_i - T_\infty}{R'_{\text{tot}}}$$

This expression can be solved for T_i , recalling that T_i also appears in θ_i .

$$T_i = \frac{T_\infty I_0(\tilde{m}r_1) + k_m 2\pi r_1 \tilde{m} R'_{\text{tot}} \left(T_a + \frac{\dot{q}_m}{\omega \rho_b c_b} \right) I_1(\tilde{m}r_1)}{I_0(\tilde{m}r_1) + k_m 2\pi r_1 \tilde{m} R'_{\text{tot}} I_1(\tilde{m}r_1)}$$

where

$$\tilde{m} = \sqrt{\omega \rho_b c_b / k_m} = \left[0.0005 \text{ s}^{-1} \times 1000 \text{ kg/m}^3 \times 3600 \text{ J/kg} \cdot \text{K} / 0.5 \text{ W/m} \cdot \text{K} \right]^{1/2} = 60 \text{ m}^{-1}$$

$$\frac{\dot{q}_m}{\omega \rho_b c_b} = \frac{700 \text{ W/m}^3}{0.0005 \text{ s}^{-1} \times 1000 \text{ kg/m}^3 \times 3600 \text{ J/kg} \cdot \text{K}} = 0.389 \text{ K}$$

and from Table B.5

$$I_0(\tilde{m}r_1) = I_0(60 \text{ m}^{-1} \times 0.05 \text{ m}) = I_0(3) = 4.88; \quad I_1(\tilde{m}r_1) = I_1(60 \text{ m}^{-1} \times 0.05 \text{ m}) = I_1(3) = 3.95$$

Thus,

$$T_i = \left[\frac{24^\circ\text{C} \times 4.88 + 0.5 \text{ W/m} \cdot \text{K}}{\times 2 \times \pi \times 0.05 \text{ m} \times 60 \text{ m}^{-1}} \right] \bigg/ \left[\frac{4.88 + 0.5 \text{ W/m} \cdot \text{K}}{\times 2 \times \pi \times 0.05 \text{ m} \times 60 \text{ m}^{-1}} \right] = 34.2^\circ\text{C} <$$

$$\left[\frac{\times 0.41 \text{ m} \cdot \text{K/W} (37 + 0.389)^\circ\text{C} \times 3.95}{\times 0.41 \text{ m} \cdot \text{K/W} \times 3.95} \right]$$

(c) The maximum temperature occurs at the centerline of the forearm, $r = 0$, thus from Equation 1, with $I_0(0) = 1$,

$$T = T_a + \frac{\dot{q}_m}{\omega \rho_b c_b} + \left(T_i - T_a - \frac{\dot{q}_m}{\omega \rho_b c_b} \right) \frac{1}{I_0(\tilde{m}r_1)} <$$

$$= 37^\circ\text{C} + 0.389^\circ\text{C} + (34.2^\circ\text{C} - 37^\circ\text{C} - 0.389^\circ\text{C}) \times \frac{1}{4.88} = 36.7^\circ\text{C}$$

COMMENTS: (1) The maximum temperature is very close to the core body temperature of 37°C , as would be expected. (2) Pennes [12] conducted an experimental investigation of the temperature distribution in human forearms, by inserting thermocouples into living subjects.

PROBLEM 4.1

KNOWN: Method of separation of variables for two-dimensional, steady-state conduction.

FIND: Show that negative or zero values of λ^2 , the separation constant, result in solutions which cannot satisfy the boundary conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: From Section 4.2, identification of the separation constant λ^2 leads to the two ordinary differential equations, 4.6 and 4.7, having the forms

$$\frac{d^2X}{dx^2} + \lambda^2 X = 0 \qquad \frac{d^2Y}{dy^2} - \lambda^2 Y = 0 \qquad (1,2)$$

and the temperature distribution is $\theta(x,y) = X(x) \cdot Y(y)$. (3)

Consider now the situation when $\lambda^2 = 0$. From Eqs. (1), (2), and (3), find that

$$X = C_1 + C_2 x, \quad Y = C_3 + C_4 y \quad \text{and} \quad \theta(x,y) = (C_1 + C_2 x) (C_3 + C_4 y). \qquad (4)$$

Evaluate the constants - C_1 , C_2 , C_3 and C_4 - by substitution of the boundary conditions:

$$\begin{array}{lll} x=0: & \theta(0,y) = (C_1 + C_2 \cdot 0)(C_3 + C_4 \cdot y) = 0 & C_1 = 0 \\ y=0: & \theta(x,0) = (0 + C_2 \cdot x)(C_3 + C_4 \cdot 0) = 0 & C_3 = 0 \\ x=L: & \theta(L,0) = (0 + C_2 \cdot L)(0 + C_4 \cdot y) = 0 & C_2 = 0 \\ y=W: & \theta(x,W) = (0 + 0 \cdot x)(0 + C_4 \cdot W) = 1 & 0 \neq 1 \end{array}$$

The last boundary condition leads to an impossibility ($0 \neq 1$). We therefore conclude that a λ^2 value of zero will not result in a form of the temperature distribution which will satisfy the boundary conditions. Consider now the situation when $\lambda^2 < 0$. The solutions to Eqs. (1) and (2) will be

$$X = C_5 e^{-\lambda x} + C_6 e^{+\lambda x}, \qquad Y = C_7 \cos \lambda y + C_8 \sin \lambda y \qquad (5,6)$$

$$\text{and} \quad \theta(x,y) = [C_5 e^{-\lambda x} + C_6 e^{+\lambda x}] [C_7 \cos \lambda y + C_8 \sin \lambda y]. \qquad (7)$$

Evaluate the constants for the boundary conditions.

$$\begin{array}{lll} y=0: & \theta(x,0) = [C_5 e^{-\lambda x} + C_6 e^{+\lambda x}] [C_7 \cos 0 + C_8 \sin 0] = 0 & C_7 = 0 \\ x=0: & \theta(0,y) = [C_5 e^0 + C_6 e^0] [0 + C_8 \sin \lambda y] = 0 & C_8 = 0 \end{array}$$

If $C_8 = 0$, a trivial solution results or $C_5 = -C_6$.

$$x=L: \quad \theta(L,y) = C_5 [e^{-\lambda L} - e^{+\lambda L}] C_8 \sin \lambda y = 0.$$

From the last boundary condition, we require C_5 or C_8 is zero; either case leads to a trivial solution with either no x or y dependence.

PROBLEM 4.2

KNOWN: Two-dimensional rectangular plate subjected to prescribed uniform temperature boundary conditions.

FIND: Temperature at the mid-point using the exact solution considering the first five non-zero terms; assess error resulting from using only first three terms. Plot the temperature distributions $T(x, 0.5)$ and $T(1, y)$.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: From Section 4.2, the temperature distribution is

$$\theta(x, y) \equiv \frac{T - T_1}{T_2 - T_1} = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + 1}{n} \sin\left(\frac{n\pi x}{L}\right) \cdot \frac{\sinh(n\pi y/L)}{\sinh(n\pi W/L)}. \quad (1,4.19)$$

Considering now the point $(x, y) = (1.0, 0.5)$ and recognizing $x/L = 1/2$, $y/L = 1/4$ and $W/L = 1/2$,

$$\theta(1, 0.5) \equiv \frac{T - T_1}{T_2 - T_1} = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + 1}{n} \sin\left(\frac{n\pi}{2}\right) \cdot \frac{\sinh(n\pi/4)}{\sinh(n\pi/2)}.$$

When n is even (2, 4, 6 ...), the corresponding term is zero; hence we need only consider $n = 1, 3, 5, 7$ and 9 as the first five non-zero terms.

$$\begin{aligned} \theta(1, 0.5) &= \frac{2}{\pi} \left\{ 2 \sin\left(\frac{\pi}{2}\right) \frac{\sinh(\pi/4)}{\sinh(\pi/2)} + \frac{2}{3} \sin\left(\frac{3\pi}{2}\right) \frac{\sinh(3\pi/4)}{\sinh(3\pi/2)} + \right. \\ &\quad \left. \frac{2}{5} \sin\left(\frac{5\pi}{2}\right) \frac{\sinh(5\pi/4)}{\sinh(5\pi/2)} + \frac{2}{7} \sin\left(\frac{7\pi}{2}\right) \frac{\sinh(7\pi/4)}{\sinh(7\pi/2)} + \frac{2}{9} \sin\left(\frac{9\pi}{2}\right) \frac{\sinh(9\pi/4)}{\sinh(9\pi/2)} \right\} \\ \theta(1, 0.5) &= \frac{2}{\pi} [0.755 - 0.063 + 0.008 - 0.001 + 0.000] = 0.445 \end{aligned} \quad (2)$$

$$T(1, 0.5) = \theta(1, 0.5)(T_2 - T_1) + T_1 = 0.445(150 - 50) + 50 = 94.5^\circ \text{C}.$$

If only the first three terms of the series, Eq. (2), are considered, the result will be $\theta(1, 0.5) = 0.46$; that is, there is less than a 0.2% effect.

Using Eq. (1), and writing out the first five terms of the series, expressions for $\theta(x, 0.5)$ or $T(x, 0.5)$ and $\theta(1, y)$ or $T(1, y)$ were keyboarded into the IHT workspace and evaluated for sweeps over the x or y variable. Note that for $T(1, y)$, that as $y \rightarrow 1$, the upper boundary, $T(1, 1)$ is greater than 150°C . Upon examination of the magnitudes of terms, it becomes evident that more than 5 terms are required to provide an accurate solution.

PROBLEM 4.3

KNOWN: Temperature distribution in the two-dimensional rectangular plate of Problem 4.2.

FIND: Expression for the heat rate per unit thickness from the lower surface ($0 \leq x \leq 2$, 0) and result based on first five non-zero terms of the infinite series.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: The heat rate per unit thickness *from the plate* along the lower surface is

$$q'_{\text{out}} = - \int_{x=0}^{x=2} dq'_y(x, 0) = - \int_{x=0}^{x=2} -k \frac{\partial T}{\partial y} \bigg|_{y=0} dx = k(T_2 - T_1) \int_{x=0}^{x=2} \frac{\partial \theta}{\partial y} \bigg|_{y=0} dx \quad (1)$$

where from the solution to Problem 4.2,

$$\theta \equiv \frac{T - T_1}{T_2 - T_1} = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + 1}{n} \sin\left(\frac{n\pi x}{L}\right) \frac{\sinh(n\pi y/L)}{\sinh(n\pi W/L)}. \quad (2)$$

Evaluate the gradient of θ from Eq. (2) and substitute into Eq. (1) to obtain

$$\begin{aligned} q'_{\text{out}} &= k(T_2 - T_1) \int_{x=0}^{x=2} \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + 1}{n} \sin\left(\frac{n\pi x}{L}\right) \frac{(n\pi/L) \cosh(n\pi y/L)}{\sinh(n\pi W/L)} \bigg|_{y=0} dx \\ q'_{\text{out}} &= k(T_2 - T_1) \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + 1}{n} \frac{1}{\sinh(n\pi W/L)} \left[-\cos\left(\frac{n\pi x}{L}\right) \right]_{x=0}^2 \\ q'_{\text{out}} &= k(T_2 - T_1) \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + 1}{n} \frac{1}{\sinh(n\pi/L)} [1 - \cos(n\pi)] \end{aligned} \quad <$$

To evaluate the first five, non-zero terms, recognize that since $\cos(n\pi) = 1$ for $n = 2, 4, 6 \dots$, only the n -odd terms will be non-zero. Hence,

Continued

PROBLEM 4.3 (Cont.)

$$q'_{\text{out}} = 50 \text{ W/m} \cdot \text{K} (150 - 50)^\circ \text{C} \frac{2}{\pi} \left\{ \frac{(-1)^2 + 1}{1} \cdot \frac{1}{\sinh(\pi/2)} (2) + \frac{(-1)^4 + 1}{3} \cdot \frac{1}{\sinh(3\pi/2)} (2) \right. \\ \left. + \frac{(-1)^6 + 1}{5} \cdot \frac{1}{\sinh(5\pi/2)} (2) + \frac{(-1)^8 + 1}{7} \cdot \frac{1}{\sinh(7\pi/2)} (2) + \frac{(-1)^{10} + 1}{9} \cdot \frac{1}{\sinh(9\pi/2)} (2) \right\}$$

$$q'_{\text{out}} = 3.183 \text{ kW/m} [1.738 + 0.024 + 0.00062 + (...)] = 5.611 \text{ kW/m} \quad <$$

COMMENTS: If the foregoing procedure were used to evaluate the heat rate into the upper surface,

$$q'_{\text{in}} = - \int_{x=0}^{x=2} dq'_y(x, W), \text{ it would follow that}$$

$$q'_{\text{in}} = k(T_2 - T_1) \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + 1}{n} \coth(n\pi/2) [1 - \cos(n\pi)]$$

However, with $\coth(n\pi/2) \geq 1$, irrespective of the value of n , and with $\sum_{n=1}^{\infty} \left[\frac{(-1)^{n+1} + 1}{n} \right]$ being a

divergent series, the complete series does not converge and $q'_{\text{in}} \rightarrow \infty$. This physically untenable condition results from the temperature discontinuities imposed at the upper left and right corners.

PROBLEM 4.4

KNOWN: Rectangular plate subjected to prescribed boundary conditions.

FIND: Steady-state temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, 2-D conduction, (2) Constant properties.

ANALYSIS: The solution follows the method of Section 4.2. The product solution is

$$T(x,y) = X(x) \cdot Y(y) = (C_1 \cos \lambda x + C_2 \sin \lambda x) (C_3 e^{-\lambda y} + C_4 e^{+\lambda y})$$

and the boundary conditions are: $T(0,y) = 0$, $T(a,y) = 0$, $T(x,0) = 0$, $T(x,b) = Ax$. Applying BC#1, $T(0,y) = 0$, find $C_1 = 0$. Applying BC#2, $T(a,y) = 0$, find that $\lambda = n\pi/a$ with $n = 1, 2, \dots$. Applying BC#3, $T(x,0) = 0$, find that $C_3 = -C_4$. Hence, the product solution is

$$T(x,y) = X(x) \cdot Y(y) = C_2 C_4 \sin \left[\frac{n\pi}{a} x \right] (e^{+\lambda y} - e^{-\lambda y}).$$

Combining constants and using superposition, find

$$T(x,y) = \sum_{n=1}^{\infty} C_n \sin \left[\frac{n\pi x}{a} \right] \sinh \left[\frac{n\pi y}{a} \right].$$

To evaluate C_n and satisfy BC#4, use orthogonal functions with Equation 4.16 to find

$$C_n = \int_0^a Ax \cdot \sin \left[\frac{n\pi x}{a} \right] \cdot dx / \sinh \left[\frac{n\pi b}{a} \right] \int_0^a \sin^2 \left[\frac{n\pi x}{a} \right] dx,$$

noting that $y = b$. The numerator, denominator and C_n , respectively, are:

$$A \int_0^a x \cdot \sin \frac{n\pi x}{a} \cdot dx = A \left[\left[\frac{a}{n\pi} \right]^2 \sin \left[\frac{n\pi x}{a} \right] - \frac{ax}{n\pi} \cos \left[\frac{n\pi x}{a} \right] \right]_0^a = \frac{Aa^2}{n\pi} [-\cos(n\pi)] = \frac{Aa^2}{n\pi} (-1)^{n+1},$$

$$\sinh \left[\frac{n\pi b}{a} \right] \int_0^a \sin^2 \frac{n\pi x}{a} \cdot dx = \sinh \left[\frac{n\pi b}{a} \right] \left[\frac{1}{2} x - \frac{a}{4n\pi} \sin \left[\frac{2n\pi x}{a} \right] \right]_0^a = \frac{a}{2} \cdot \sinh \left[\frac{n\pi b}{a} \right],$$

$$C_n = \frac{Aa^2}{n\pi} (-1)^{n+1} / \frac{a}{2} \sinh \left[\frac{n\pi b}{a} \right] = 2Aa (-1)^{n+1} / n\pi \sinh \left[\frac{n\pi b}{a} \right].$$

Hence, the temperature distribution is

$$T(x,y) = \frac{2Aa}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \cdot \sin \left[\frac{n\pi x}{a} \right] \frac{\sinh \left[\frac{n\pi y}{a} \right]}{\sinh \left[\frac{n\pi b}{a} \right]}.$$

<

PROBLEM 4.5

KNOWN: Boundary conditions on four sides of a rectangular plate.

FIND: Temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: This problem differs from the one solved in Section 4.2 only in the boundary condition at the top surface. Defining $\theta = T - T_\infty$, the differential equation and boundary conditions are

$$\frac{\partial^2 \theta}{\partial x^2} + \frac{\partial^2 \theta}{\partial y^2} = 0$$

$$\theta(0, y) = 0 \quad \theta(L, y) = 0 \quad \theta(x, 0) = 0 \quad k \left. \frac{\partial \theta}{\partial y} \right|_{y=W} = q_s'' \quad (1a,b,c,d)$$

The solution is identical to that in Section 4.2 through Equation (4.11),

$$\theta = \sum_{n=1}^{\infty} C_n \sin \frac{n\pi x}{L} \sinh \frac{n\pi y}{L} \quad (2)$$

To determine C_n , we now apply the top surface boundary condition, Equation (1d). Differentiating Equation (2) yields

Continued....

PROBLEM 4.5 (Cont.)

$$\left. \frac{\partial \theta}{\partial y} \right|_{y=W} = \sum_{n=1}^{\infty} C_n \frac{n\pi}{L} \sin \frac{n\pi x}{L} \cosh \frac{n\pi W}{L} \quad (3)$$

Substituting this into Equation (1d) results in

$$\frac{q_s''}{k} = \sum_{n=1}^{\infty} A_n \sin \frac{n\pi x}{L} \quad (4)$$

where $A_n = C_n(n\pi/L)\cosh(n\pi W/L)$. The principles expressed in Equations (4.13) through (4.16) still apply, but now with reference to Equation (4) and Equation (4.14), we should choose

$f(x) = q_s''/k$, $g_n(x) = \sin \frac{n\pi x}{L}$. Equation (4.16) then becomes

$$A_n = \frac{\frac{q_s''}{k} \int_0^L \sin \frac{n\pi x}{L} dx}{\int_0^L \sin^2 \frac{n\pi x}{L} dx} = \frac{q_s''}{k} \frac{2}{\pi} \frac{(-1)^{n+1} + 1}{n}$$

Thus

$$C_n = 2 \frac{q_s'' L}{k n^2 \pi^2 \cosh(n\pi W/L)} \frac{(-1)^{n+1} + 1}{n} \quad (5)$$

The solution is given by Equation (2) with C_n defined by Equation (5).

PROBLEM 4.6

KNOWN: Uniform media of prescribed geometry.

FIND: (a) Shape factor expressions from thermal resistance relations for the plane wall, cylindrical shell and spherical shell, (b) Shape factor expression for the isothermal sphere of diameter D buried in an infinite medium.

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform properties.

ANALYSIS: (a) The relationship between the shape factor and thermal resistance of a shape follows from their definitions in terms of heat rates and overall temperature differences.

$$q = k\Delta T \quad (4.20), \quad q = \frac{\Delta T}{R_t} \quad (3.19), \quad S = 1/kR_t \quad (4.21)$$

Using the thermal resistance relations developed in Chapter 3, their corresponding shape factors are:

Plane wall:

$$R_t = \frac{L}{kA} \quad S = \frac{A}{L} \quad <$$

Cylindrical shell:

$$R_t = \frac{\ln(r_2/r_1)}{2\pi Lk} \quad S = \frac{2\pi L}{\ln r_2/r_1} \quad <$$

(L into the page)

Spherical shell:

$$R_t = \frac{1}{4\pi k} \left[\frac{1}{r_1} - \frac{1}{r_2} \right] \quad S = \frac{4\pi}{1/r_1 - 1/r_2} \quad <$$

(b) The shape factor for the sphere of diameter D in an infinite medium can be derived using the alternative conduction analysis of Section 3.2. For this situation, q_r is a constant and Fourier's law has the form

$$q_r = -k(4\pi r^2) \frac{dT}{dr}.$$

Separate variables, identify limits and integrate.

$$-\frac{q_r}{4\pi k} \int_{D/2}^{\infty} \frac{dr}{r^2} = \int_{T_1}^{T_2} dT \quad -\frac{q_r}{4\pi k} \left[-\frac{1}{r} \right]_{D/2}^{\infty} = -\frac{q_r}{4\pi k} \left[0 - \frac{2}{D} \right] = (T_2 - T_1)$$

$$q_r = 4\pi k \left[\frac{D}{2} \right] (T_1 - T_2) \quad \text{or} \quad S = 2\pi D. \quad <$$

COMMENTS: Note that the result for the buried sphere, $S = 2\pi D$, can be obtained from the expression for the spherical shell with $r_2 = \infty$. Also, the shape factor expression for the “isothermal sphere buried in a semi-infinite medium” presented in Table 4.1 provides the same result with $z \rightarrow \infty$.

PROBLEM 4.7

KNOWN: Boundary conditions on four sides of a square plate.

FIND: Expressions for shape factors associated with the *maximum* and *average* top surface temperatures. Values of these shape factors. The maximum and average temperatures for specified conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: We must first find the temperature distribution as in Problem 4.5. Problem 4.5 differs from the problem solved in Section 4.2 only in the boundary condition at the top surface. Defining $\theta = T - T_\infty$, the differential equation and boundary conditions are

$$\frac{\partial^2 \theta}{\partial x^2} + \frac{\partial^2 \theta}{\partial y^2} = 0$$

$$\theta(0, y) = 0 \quad \theta(L, y) = 0 \quad \theta(x, 0) = 0 \quad k \frac{\partial \theta}{\partial y} \bigg|_{y=W} = q_s'' \quad (1a, b, c, d)$$

The solution is identical to that in Section 4.2 through Equation (4.11),

$$\theta = \sum_{n=1}^{\infty} C_n \sin \frac{n\pi x}{L} \sinh \frac{n\pi y}{L} \quad (2)$$

To determine C_n , we now apply the top surface boundary condition, Equation (1d). Differentiating Equation (2) yields

$$\frac{\partial \theta}{\partial y} \bigg|_{y=W} = \sum_{n=1}^{\infty} C_n \frac{n\pi}{L} \sin \frac{n\pi x}{L} \cosh \frac{n\pi W}{L} \quad (3)$$

Continued

PROBLEM 4.7 (Cont.)

Substituting this into Equation (1d) results in

$$\frac{q_s''}{k} = \sum_{n=1}^{\infty} A_n \sin \frac{n\pi x}{L} \quad (4)$$

where $A_n = C_n(n\pi/L)\cosh(n\pi W/L)$. The principles expressed in Equations (4.13) through (4.16) still apply, but now with reference to Equation (4) and Equation (4.14), we should choose

$f(x) = q_s''/k$, $g_n(x) = \sin \frac{n\pi x}{L}$. Equation (4.16) then becomes

$$A_n = \frac{\frac{q_s''}{k} \int_0^L \sin \frac{n\pi x}{L} dx}{\int_0^L \sin^2 \frac{n\pi x}{L} dx} = \frac{q_s''}{k} \frac{2}{\pi} \frac{(-1)^{n+1} + 1}{n}$$

Thus

$$C_n = 2 \frac{q_s'' L}{k} \frac{(-1)^{n+1} + 1}{n^2 \pi^2 \cosh(n\pi W/L)} \quad (5)$$

The solution is given by Equation (2) with C_n defined by Equation (5). We now proceed to evaluate the shape factors.

(a) The maximum top surface temperature occurs at the midpoint of that surface, $x = W/2$, $y = W$. From Equation (2) with $L = W$,

$$\theta(W/2, W) = T_{2,\max} - T_1 = \sum_{n=1}^{\infty} C_n \sin \frac{n\pi}{2} \sinh n\pi = \sum_{n \text{ odd}} C_n (-1)^{(n-1)/2} \sinh n\pi$$

where

$$C_n = 2 \frac{q_s'' W}{k} \frac{(-1)^{n+1} + 1}{n^2 \pi^2 \cosh n\pi}$$

Thus

$$S_{\max} = \frac{q_s'' W d}{k(T_{2,\max} - T_1)} = \left[\frac{2}{d} \sum_{n \text{ odd}} \frac{(-1)^{n+1} + 1}{n^2 \pi^2} (-1)^{(n-1)/2} \tanh n\pi \right]^{-1} = \left[\frac{4}{d} \sum_{n \text{ odd}} \frac{(-1)^{(n-1)/2}}{n^2 \pi^2} \tanh n\pi \right]^{-1} <$$

where d is the depth of the rectangle into the page.

Continued...

PROBLEM 4.7 (Cont.)

(b) The average top surface temperature is given by

$$\bar{\theta}(y=W) = \bar{T}_2 - T_1 = \sum_{n=1}^{\infty} C_n \frac{1}{W} \int_0^W \sin \frac{n\pi x}{W} dx \sinh n\pi = \sum_{n=1}^{\infty} C_n \frac{1 - (-1)^n}{n\pi} \sinh n\pi$$

Thus

$$\bar{S} = \frac{q_s'' W d}{k(\bar{T}_2 - T_1)} = \left[\frac{2}{d} \sum_{n=1}^{\infty} \frac{[(-1)^{n+1} + 1][1 - (-1)^n]}{n^3 \pi^3} \tanh n\pi \right]^{-1} = \left[\frac{8}{d} \sum_{n \text{ odd}} \frac{1}{n^3 \pi^3} \tanh n\pi \right]^{-1} \quad <$$

(c) Evaluating the expressions for the shape factors yields

$$\frac{S_{\max}}{d} = \left[4 \sum_{n \text{ odd}} \frac{(-1)^{(n-1)/2}}{n^2 \pi^2} \tanh n\pi \right]^{-1} = 2.70 \quad <$$

$$\frac{\bar{S}}{d} = \left[8 \sum_{n \text{ odd}} \frac{1}{n^3 \pi^3} \tanh n\pi \right]^{-1} = 3.70 \quad <$$

The temperatures can then be found from

$$T_{2,\max} = T_1 + \frac{q}{S_{\max} k} = T_1 + \frac{q_s'' W d}{S_{\max} k} = 0^\circ\text{C} + \frac{1000 \text{ W/m}^2 \times 0.01 \text{ m}}{2.70 \times 20 \text{ W/m} \cdot \text{K}} = 0.19^\circ\text{C} \quad <$$

$$\bar{T}_2 = T_1 + \frac{q}{\bar{S} k} = T_1 + \frac{q_s'' W d}{\bar{S} k} = 0^\circ\text{C} + \frac{1000 \text{ W/m}^2 \times 0.01 \text{ m}}{3.70 \times 20 \text{ W/m} \cdot \text{K}} = 0.14^\circ\text{C} \quad <$$

PROBLEM 4.8

KNOWN: Shape of objects at surface of semi-infinite medium.

FIND: Shape factors between object at temperature T_1 and semi-infinite medium at temperature T_2 .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Medium is semi-infinite, (3) Constant properties, (4) Surface of semi-infinite medium is adiabatic.

ANALYSIS: Cases 12 -15 of Table 4.1 all pertain to objects buried in an infinite medium. Since they all possess symmetry about a horizontal plane that bisects the object, they are equivalent to the cases given in this problem for which the horizontal plane is adiabatic. In particular, the heat flux is the same for the cases of this problem as for the cases of Table 4.1. Note, that when we use Table 4.1 to determine the dimensionless conduction heat rate, q_{ss}^* , we must be consistent and use the surface area of the “entire” object of Table 4.1, not the “half” object of this problem. Then

$$q'' = \frac{q}{A_s} = \frac{q_{ss}^* k(T_1 - T_2)}{L_c}$$

where $L_c = (A_s/4\pi)^{1/2}$ and A_s is the area given in Table 4.1

When we calculate the shape factors we must account for the fact that the surface areas and heat transfer rates for the objects of this problem are half as much as for the objects of Table 4.1.

$$S = \frac{q}{k(T_1 - T_2)} = \frac{q'' A_s/2}{k(T_1 - T_2)} = \frac{q_{ss}^* A_s}{2L_c} = \frac{q_{ss}^* (4\pi A_s)^{1/2}}{2}$$

where A_s is still the area in table 4.1 and the 2 in the denominator accounts for the area being halved. Thus, finally,

$$S = q_{ss}^* (\pi A_s)^{1/2}$$

$$(a) \quad S = 1 \cdot (\pi \cdot \pi D^2)^{1/2} = \pi D \quad <$$

$$(b) \quad S = \frac{2\sqrt{2}}{\pi} \left(\pi \cdot \frac{\pi D^2}{2} \right)^{1/2} = 2D \quad <$$

This agrees with Table 4.1a, Case 10.

$$(c) \quad S = 0.932(\pi \cdot 2D^2)^{1/2} = \sqrt{2\pi}(0.932)D = 2.34D \quad <$$

(d) The height of the “whole object” is $d = 2D$. Thus

$$S = 0.961 \left[\pi (2D^2 + 4D \cdot 2D) \right]^{1/2} = \sqrt{10\pi}(0.961)D = 5.39D \quad <$$

PROBLEM 4.9

KNOWN: Heat generation in a buried spherical container.

FIND: (a) Outer surface temperature of the container, (b) Representative isotherms and heat flow lines.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Soil is a homogeneous medium with constant properties.

PROPERTIES: Table A-3, Soil (300K): $k = 0.52 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) From an energy balance on the container, $q = \dot{E}_g$ and from the first entry in Table 4.1,

$$q = \frac{2\pi D}{1 - D/4z} k (T_1 - T_2).$$

Hence,

$$T_1 = T_2 + \frac{q}{k} \frac{1 - D/4z}{2\pi D} = 20^\circ\text{C} + \frac{500\text{W}}{0.52 \frac{\text{W}}{\text{m}\cdot\text{K}}} \frac{1 - 2\text{m}/40\text{m}}{2\pi(2\text{m})} = 92.7^\circ\text{C} \quad <$$

(b) The isotherms may be viewed as spherical surfaces whose center moves downward with increasing radius. The surface of the soil is an isotherm for which the center is at $z = \infty$.

PROBLEM 4.10

KNOWN: Temperature, diameter and burial depth of an insulated pipe.

FIND: Heat loss per unit length of pipe.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction through insulation, two-dimensional through soil, (3) Constant properties, (4) Negligible oil convection and pipe wall conduction resistances.

PROPERTIES: Table A-3, Soil (300K): $k = 0.52 \text{ W/m}\cdot\text{K}$; Table A-3, Cellular glass (365K): $k = 0.069 \text{ W/m}\cdot\text{K}$.

ANALYSIS: The heat rate can be expressed as

$$q = \frac{T_1 - T_2}{R_{\text{tot}}}$$

where the thermal resistance is $R_{\text{tot}} = R_{\text{ins}} + R_{\text{soil}}$. From Equation 3.28,

$$R_{\text{ins}} = \frac{\ln(D_2/D_1)}{2\pi L k_{\text{ins}}} = \frac{\ln(0.7\text{m}/0.5\text{m})}{2\pi L \times 0.069 \text{ W/m}\cdot\text{K}} = \frac{0.776\text{m}\cdot\text{K/W}}{L}.$$

From Equation 4.21 and Table 4.1,

$$R_{\text{soil}} = \frac{1}{S k_{\text{soil}}} = \frac{\cosh^{-1}(2z/D_2)}{2\pi L k_{\text{soil}}} = \frac{\cosh^{-1}(3/0.7)}{2\pi \times (0.52 \text{ W/m}\cdot\text{K}) L} = \frac{0.653}{L} \text{m}\cdot\text{K/W}.$$

Hence,

$$q = \frac{(120 - 0)^\circ\text{C}}{\frac{1}{L}(0.776 + 0.653) \frac{\text{m}\cdot\text{K}}{\text{W}}} = 84 \frac{\text{W}}{\text{m}} \times L$$

$$q' = q/L = 84 \text{ W/m}.$$

<

COMMENTS: (1) Contributions of the soil and insulation to the total resistance are approximately the same. The heat loss may be reduced by burying the pipe deeper or adding more insulation.

(2) The convection resistance associated with the oil flow through the pipe may be significant, in which case the foregoing result would overestimate the heat loss. A calculation of this resistance may be based on results presented in Chapter 8.

(3) Since $z > 3D/2$, the shape factor for the soil can also be evaluated from $S = 2\pi L / \ln(4z/D)$ of Table 4.1, and an equivalent result is obtained.

PROBLEM 4.11

KNOWN: Operating conditions of a buried superconducting cable.

FIND: Required cooling load.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Two-dimensional conduction in soil, (4) One-dimensional conduction in insulation, (5) Pipe inner surface is at liquid nitrogen temperature.

ANALYSIS: The heat rate per unit length is

$$q' = \frac{T_g - T_n}{R'_g + R'_I}$$

$$q' = \frac{T_g - T_n}{\left[k_g \left(2\pi / \ln(4z/D_o) \right) \right]^{-1} + \ln(D_o / D_i) / 2\pi k_i}$$

where Tables 3.3 and 4.1 have been used to evaluate the insulation and ground resistances, respectively. Hence,

$$q' = \frac{(300 - 77) \text{ K}}{\left[(1.2 \text{ W/m} \cdot \text{K}) \left(2\pi / \ln(8/0.2) \right) \right]^{-1} + \ln(2) / 2\pi \times 0.005 \text{ W/m} \cdot \text{K}}$$

$$q' = \frac{223 \text{ K}}{(0.489 + 22.064) \text{ m} \cdot \text{K/W}}$$

$$q' = 9.9 \text{ W/m.}$$

<

COMMENTS: The heat gain is small and the dominant contribution to the thermal resistance is made by the insulation.

PROBLEM 4.12

KNOWN: Electrical heater of cylindrical shape inserted into a hole drilled normal to the surface of a large block of material with prescribed thermal conductivity.

FIND: Temperature reached when heater dissipates 50 W with the block at 25°C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Block approximates semi-infinite medium with constant properties, (3) Negligible heat loss to surroundings above block surface, (4) Heater can be approximated as isothermal at T_1 .

ANALYSIS: The temperature of the heater surface follows from the rate equation written as

$$T_1 = T_2 + q/kS$$

where S can be estimated from the conduction shape factor given in Table 4.1 for a "vertical cylinder in a semi-infinite medium,"

$$S = 2\pi L / \ln(4L/D).$$

Substituting numerical values, find

$$S = 2\pi \times 0.1\text{ m} / \ln\left[\frac{4 \times 0.1\text{ m}}{0.005\text{ m}}\right] = 0.143\text{ m}.$$

The temperature of the heater is then

$$T_1 = 25^\circ\text{C} + 50\text{ W} / (5\text{ W/m}\cdot\text{K} \times 0.143\text{ m}) = 94.9^\circ\text{C}.$$

<

COMMENTS: (1) Note that the heater has $L \gg D$, which is a requirement of the shape factor expression.

(2) Our calculation presumes there is negligible thermal contact resistance between the heater and the medium. In practice, this would not be the case unless a conducting paste were used.

(3) Since $L \gg D$, assumption (3) is reasonable.

(4) This configuration has been used to determine the thermal conductivity of materials from measurement of q and T_1 .

PROBLEM 4.13

KNOWN: Surface temperatures of two parallel pipe lines buried in soil.

FIND: Heat transfer per unit length between the pipe lines.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) Pipe lines are buried very deeply, approximating burial in an infinite medium, (5) Pipe length $\gg D_1$ or D_2 and $w > D_1$ or D_2 .

ANALYSIS: The heat transfer rate per unit length from the hot pipe to the cool pipe is

$$q' = \frac{q}{L} = \frac{S}{L} k (T_1 - T_2).$$

The shape factor S for this configuration is given in Table 4.1 as

$$S = \frac{2\pi L}{\cosh^{-1} \left[\frac{4w^2 - D_1^2 - D_2^2}{2D_1 D_2} \right]}.$$

Substituting numerical values,

$$\frac{S}{L} = 2\pi / \cosh^{-1} \left[\frac{4 \times (0.5\text{m})^2 - (0.1\text{m})^2 - (0.075\text{m})^2}{2 \times 0.1\text{m} \times 0.075\text{m}} \right] = 2\pi / \cosh^{-1}(65.63)$$

$$\frac{S}{L} = 2\pi / 4.88 = 1.29.$$

Hence, the heat rate per unit length is

$$q' = 1.29 \times 0.5 \text{ W/m} \cdot \text{K} (175 - 5)^\circ \text{C} = 110 \text{ W/m}.$$

<

COMMENTS: The heat gain to the cooler pipe line will be larger than 110 W/m if the soil temperature is greater than 5°C. How would you estimate the heat gain if the soil were at 25°C?

PROBLEM 4.14

KNOWN: Tube embedded in the center plane of a concrete slab.

FIND: The shape factor and heat transfer rate per unit length using the appropriate tabulated relation,

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties, (4) Concrete slab infinitely long in horizontal plane, $L \gg z$.

PROPERTIES: Table A-3, Concrete, stone mix (300K): $k = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: If we relax the restriction that $z \gg D/2$, the embedded tube-slab system corresponds to the fifth case of Table 4.1. Hence,

$$S = \frac{2\pi L}{\ln(8z/\pi D)}$$

where L is the length of the system normal to the page, z is the half-thickness of the slab and D is the diameter of the tube. Substituting numerical values, find

$$S = 2\pi L / \ln(8 \times 50\text{mm} / \pi 50\text{mm}) = 6.72L.$$

Hence, the heat rate per unit length is

$$q' = \frac{q}{L} = \frac{S}{L} k (T_1 - T_2) = 6.72 \times 1.4 \frac{\text{W}}{\text{m}\cdot\text{K}} (85 - 20)^\circ \text{C} = 612 \text{ W}.$$

PROBLEM 4.15

KNOWN: Dimensions and boundary temperatures of a steam pipe embedded in a concrete casing.

FIND: Heat loss per unit length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible steam side convection resistance, pipe wall resistance and contact resistance ($T_1 = 450\text{ K}$), (3) Constant properties.

PROPERTIES: Table A-3, Concrete (300K): $k = 1.4\text{ W/m}\cdot\text{K}$.

ANALYSIS: The heat rate can be expressed as

$$q = Sk\Delta T_{1-2} = Sk(T_1 - T_2)$$

From Table 4.1, the shape factor is

$$S = \frac{2\pi L}{\ln\left[\frac{1.08 w}{D}\right]}$$

Hence,

$$q' = \left[\frac{q}{L}\right] = \frac{2\pi k(T_1 - T_2)}{\ln\left[\frac{1.08 w}{D}\right]}$$

$$q' = \frac{2\pi \times 1.4\text{ W/m}\cdot\text{K} \times (450 - 300)\text{ K}}{\ln\left[\frac{1.08 \times 1.5\text{ m}}{0.5\text{ m}}\right]} = 1122\text{ W/m.}$$

<

COMMENTS: Having neglected the steam side convection resistance, the pipe wall resistance, and the contact resistance, the foregoing result overestimates the actual heat loss.

PROBLEM 4.16

KNOWN: Thin-walled copper tube enclosed by an eccentric cylindrical shell; intervening space filled with insulation.

FIND: Heat loss per unit length of tube; compare result with that of a concentric tube-shell arrangement.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Thermal resistances of copper tube wall and outer shell wall are negligible, (4) Two-dimensional conduction in insulation.

ANALYSIS: The heat loss per unit length written in terms of the shape factor S is

$q' = k(S/\ell)(T_1 - T_2)$ and from Table 4.1 for this geometry,

$$\frac{S}{\ell} = 2\pi / \cosh^{-1} \left[\frac{D^2 + d^2 - 4z^2}{2Dd} \right].$$

Substituting numerical values, all dimensions in mm,

$$\frac{S}{\ell} = 2\pi / \cosh^{-1} \left[\frac{120^2 + 30^2 - 4(20)^2}{2 \times 120 \times 30} \right] = 2\pi / \cosh^{-1}(1.903) = 4.991.$$

Hence, the heat loss is

$$q' = 0.05 \text{ W/m} \cdot \text{K} \times 4.991 (85 - 35)^\circ \text{C} = 12.5 \text{ W/m}.$$

<

If the copper tube were concentric with the shell, but all other conditions were the same, the heat loss would be

$$q'_c = \frac{2\pi k (T_1 - T_2)}{\ln(D_2/D_1)}$$

using Eq. 3.27. Substituting numerical values,

$$q'_c = 2\pi \times 0.05 \frac{\text{W}}{\text{m} \cdot \text{K}} (85 - 35)^\circ \text{C} / \ln(120/30)$$

$$q'_c = 11.3 \text{ W/m}.$$

COMMENTS: As expected, the heat loss with the eccentric arrangement is larger than that for the concentric arrangement. The effect of the eccentricity is to increase the heat loss by $(12.5 - 11.3)/11.3 \approx 11\%$.

PROBLEM 4.17

KNOWN: Cubical furnace, 350 mm external dimensions, with 50 mm thick walls.

FIND: The heat loss, $q(W)$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

PROPERTIES: Table A-3, Fireclay brick ($\bar{T} = (T_1 + T_2)/2 = 610\text{K}$): $k \approx 1.1 \text{ W/m} \cdot \text{K}$.

ANALYSIS: Using relations for the shape factor from Table 4.1,

$$\text{Plane Walls (6)} \quad S_W = \frac{A}{L} = \frac{0.25 \times 0.25 \text{m}^2}{0.05 \text{m}} = 1.25 \text{m}$$

$$\text{Edges (12)} \quad S_E = 0.54D = 0.54 \times 0.25 \text{m} = 0.14 \text{m}$$

$$\text{Corners (8)} \quad S_C = 0.15L = 0.15 \times 0.05 \text{m} = 0.008 \text{m}.$$

The heat rate in terms of the shape factors is

$$q = kS(T_1 - T_2) = k(6S_W + 12S_E + 8S_C)(T_1 - T_2)$$

$$q = 1.1 \frac{\text{W}}{\text{m} \cdot \text{K}} (6 \times 1.25 \text{m} + 12 \times 0.14 \text{m} + 8 \times 0.008 \text{m}) (600 - 75)^\circ \text{C}$$

$$q = 5.30 \text{ kW}.$$

<

COMMENTS: Note that the restrictions for S_E and S_C have been met.

PROBLEM 4.18

KNOWN: Power, size and shape of laser beam. Material properties.

FIND: Maximum surface temperature for a Gaussian beam, maximum temperature for a flat beam, and average temperature for a flat beam.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Semi-infinite medium, (4) Negligible heat loss from the top surface.

ANALYSIS: The shape factor is defined in Eq. 4.20 and is $q = Sk\Delta T_{1-2}$ (1)

From the problem statement and Section 4.3, the shape factors for the three cases are:

Beam Shape	Shape Factor	$T_{1,\text{avg}}$ or $T_{1,\text{max}}$
Gaussian	$2\sqrt{\pi}r_b$	$T_{1,\text{max}}$
Flat	πr_b	$T_{1,\text{max}}$
Flat	$3\pi^2 r_b / 8$	$T_{1,\text{avg}}$

For the Gaussian beam, $S_1 = 2\sqrt{\pi} \times 0.1 \times 10^{-3} \text{ m} = 354 \times 10^{-6} \text{ m}$

For the flat beam (max. temperature), $S_2 = \pi \times 0.1 \times 10^{-3} \text{ m} = 314 \times 10^{-6} \text{ m}$

For the flat beam (avg. temperature), $S_3 = (3/8) \times \pi^2 \times 0.1 \times 10^{-3} \text{ m} = 370 \times 10^{-6} \text{ m}$

The temperature at the heated surface for the three cases is evaluated from Eq. (1) as

$$T_1 = T_2 + q/Sk = T_2 + P\alpha/Sk$$

For the Gaussian beam, $T_{1,\text{max}} = 25^\circ\text{C} + 1 \text{ W} \times 0.45 / (354 \times 10^{-6} \text{ m} \times 27 \text{ W/m}\cdot\text{K}) = 72.1^\circ\text{C} <$

For the flat beam (T_{max}), $T_{1,\text{max}} = 25^\circ\text{C} + 1 \text{ W} \times 0.45 / (314 \times 10^{-6} \text{ m} \times 27 \text{ W/m}\cdot\text{K}) = 78.1^\circ\text{C} <$

For the flat beam (T_{avg}), $T_{1,\text{avg}} = 25^\circ\text{C} + 1 \text{ W} \times 0.45 / (370 \times 10^{-6} \text{ m} \times 27 \text{ W/m}\cdot\text{K}) = 70.0^\circ\text{C} <$

COMMENTS: (1) The maximum temperature occurs at $r = 0$ for all cases. For the flat beam, the maximum temperature exceeds the average temperature by $78.1 - 70.0 = 8.1$ degrees Celsius.

PROBLEM 4.19

KNOWN: Relation between maximum material temperature and its location, and scanning velocities.

FIND: (a) Required laser power to achieve a desired operating temperature for given material, beam size and velocity, (b) Lag distance separating the center of the beam and the location of maximum temperature, (c) Plot of the required laser power for velocities in the range $0 \leq U \leq 2$ m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Semi-infinite medium, (4) Negligible heat loss from the top surface.

ANALYSIS: The thermal diffusivity of the materials is

$$\alpha = k/\rho c = 27 \text{ W/m} \cdot \text{K} / (2000 \text{ kg/m}^3 \cdot 800 \text{ J/kg} \cdot \text{K}) = 16.9 \times 10^{-6} \text{ m}^2/\text{s}$$

(a) The Peclet number is

$$\text{Pe} = U r_b / \sqrt{2} \alpha = 2 \text{ m/s} \times 0.0001 \text{ m} / (\sqrt{2} \times 16.9 \times 10^{-6} \text{ m}^2/\text{s}) = 8.38$$

Since this value of the Peclet number is within the range of the correlation provided in the problem statement, the maximum temperature corresponding to a stationary beam delivering the same power would be

$$\begin{aligned} T_{l,\max,U=0} &= (1 + 0.301\text{Pe} - 0.0108\text{Pe}^2) (T_{l,\max,U \neq 0} - T_2) + T_2 \\ &= (1 + 0.301 \times 8.37 - 0.0108 \times 8.37^2) \times (200 - 25)^\circ\text{C} + 25^\circ\text{C} \\ &= 509^\circ\text{C}. \end{aligned}$$

From Eq. 4.20 and Problem 4.18 we know that (with the symbol $\hat{\alpha}$ now representing the absorptivity, since α is used for thermal diffusivity)

Continued...

PROBLEM 4.19 (Cont.)

$$P = Sk\Delta T_{1-2} / \hat{\alpha} = 2\sqrt{\pi}r_b k\Delta T_{1-2} / \hat{\alpha} = 2\sqrt{\pi} \times 0.0001 \text{ m} \times 27 \text{ W/m} \cdot \text{K} \times (509 - 25)^\circ\text{C} / 0.45 = 10.3 \text{ W} \quad <$$

(b) The lag distance is

$$\delta = 0.944 \frac{\alpha}{U} \text{Pe}^{1.55} = 0.944 \times \frac{16.9 \times 10^{-6} \text{ m}^2/\text{s}}{2 \text{ m/s}} \times 8.37^{1.55} = 0.21 \text{ mm} \quad <$$

(c) The plot of the required laser power versus scanning velocity is shown below.

COMMENTS: (1) The required laser power increases as the scanning velocity increases since more material must be heated at higher scanning velocities. (2) The relative motion between the laser beam and the heated material represents an advection process. Advective effects will be dealt with extensively in Chapters 6 through 9.

PROBLEM 4.20

KNOWN: Dimensions, thermal conductivity and inner surface temperature of furnace wall. Ambient conditions.

FIND: Heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Uniform convection coefficient over entire outer surface of container, (3) Negligible radiation losses.

ANALYSIS: From the thermal circuit, the heat loss is

$$q = \frac{T_{s,i} - T_{\infty}}{R_{\text{cond}(2D)} + R_{\text{conv}}}$$

where $R_{\text{conv}} = 1/hA_{s,o} = 1/6(hW^2) = 1/6[5 \text{ W/m}^2 \cdot \text{K}(5 \text{ m})^2] = 0.00133 \text{ K/W}$. From Equation (4.21), the two-dimensional conduction resistance is

$$R_{\text{cond}(2D)} = \frac{1}{Sk}$$

where the shape factor S must include the effects of conduction through the 8 corners, 12 edges and 6 plane walls. Hence, using the relations for Cases 8 and 9 of Table 4.1,

$$S = 8(0.15L) + 12 \times 0.54(W - 2L) + 6A_{s,i}/L$$

where $A_{s,i} = (W - 2L)^2$. Hence,

$$S = [8(0.15 \times 0.35) + 12 \times 0.54(4.30) + 6(52.83)] \text{ m}$$

$$S = (0.42 + 27.86 + 316.98) \text{ m} = 345.26 \text{ m}$$

and $R_{\text{cond}(2D)} = 1/(345.26 \text{ m} \times 1.4 \text{ W/m} \cdot \text{K}) = 0.00207 \text{ K/W}$. Hence

$$q = \frac{(1100 - 25)^{\circ} \text{C}}{(0.00207 + 0.00133) \text{ K/W}} = 316 \text{ kW}$$

<

COMMENTS: The heat loss is extremely large and measures should be taken to insulate the furnace. Radiation losses may be significant, leading to larger heat losses.

PROBLEM 4.21

KNOWN: Platen heated by passage of hot fluid in poor thermal contact with cover plates exposed to cooler ambient air.

FIND: (a) Heat rate per unit thickness from each channel, q'_i , (b) Surface temperature of cover plate, T_s , (c) q'_i and T_s if lower surface is perfectly insulated, (d) Effect of changing centerline spacing on q'_i and T_s

SCHEMATIC:

$$\begin{aligned} D &= 15 \text{ mm} & L_o &= 60 \text{ mm} \\ L_A &= 30 \text{ mm} & L_B &= 7.5 \text{ mm} \\ T_i &= 150^\circ\text{C} & h_i &= 1000 \text{ W/m}^2\cdot\text{K} \\ T_\infty &= 25^\circ\text{C} & h_o &= 200 \text{ W/m}^2\cdot\text{K} \\ k_A &= 20 \text{ W/m}\cdot\text{K} & k_B &= 75 \text{ W/m}\cdot\text{K} \\ R''_{t,c} &= 2.0 \times 10^{-4} \text{ m}^2\cdot\text{K/W} & S' &= 4.25 \end{aligned}$$

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction in platen, but one-dimensional in coverplate, (3) Temperature of interfaces between A and B is uniform, (4) Constant properties.

ANALYSIS: (a) The heat rate per unit thickness from each channel can be determined from the following thermal circuit representing the quarter section shown.

The value for the shape factor for the quarter section is $S' = 4.25/4 = 1.06$. Hence, the heat rate is

$$q'_i = 4(T_i - T_\infty)/R'_{\text{tot}} \quad (1)$$

$$\begin{aligned} R'_{\text{tot}} &= [1/1000 \text{ W/m}^2\cdot\text{K}(\pi 0.015\text{m}/4) + 1/20 \text{ W/m}\cdot\text{K} \times 1.06 \\ &\quad + 2.0 \times 10^{-4} \text{ m}^2\cdot\text{K/W}/(0.060\text{m}/2) + 0.0075\text{m}/75 \text{ W/m}\cdot\text{K}(0.060\text{m}/2) \\ &\quad + 1/200 \text{ W/m}^2\cdot\text{K}(0.060\text{m}/2)] \end{aligned}$$

$$\begin{aligned} R'_{\text{tot}} &= [0.085 + 0.047 + 0.0067 + 0.0033 + 0.1667] \text{ m}\cdot\text{K/W} \\ R'_{\text{tot}} &= 0.309 \text{ m}\cdot\text{K/W} \end{aligned}$$

$$q'_i = 4(150 - 25) \text{ K}/0.309 \text{ m}\cdot\text{K/W} = 1.62 \text{ kW/m}. \quad <$$

(b) The surface temperature of the cover plate also follows from the thermal circuit as

$$q'_i/4 = \frac{T_s - T_\infty}{1/h_o(L_o/2)} \quad (2)$$

Continued

PROBLEM 4.21 (Cont.)

$$T_s = T_\infty + \frac{q'_i}{4 h_o (L_o/2)} = 25^\circ\text{C} + \frac{1.62 \text{ kW}}{4} \times 0.167 \text{ m} \cdot \text{K/W}$$

$$T_s = 25^\circ\text{C} + 67.6^\circ\text{C} \approx 93^\circ\text{C}.$$

<

(c) The effect of the centerline spacing on q'_i and T_s can be understood by examining the relative magnitudes of the thermal resistances. The dominant resistance is that due to the ambient air convection process which is inversely related to the spacing L_o . Hence, from Equation (1), the heat rate will increase nearly linearly with an increase in L_o ,

$$q'_i \sim \frac{1}{R'_{\text{tot}}} \approx \frac{1}{1/h_o (L_o/2)} \sim L_o.$$

From Eq. (2), find

$$\Delta T = T_s - T_\infty = \frac{q'_i}{4 h_o (L_o/2)} \sim q'_i \cdot L_o^{-1} \sim L_o \cdot L_o^{-1} \approx 1.$$

Hence we conclude that ΔT will not increase with a change in L_o . Does this seem reasonable? What effect does L_o have on Assumptions (2) and (3)?

If the lower surface were insulated, the heat rate would be decreased nearly by half. This follows again from the fact that the overall resistance is dominated by the surface convection process. The temperature difference, $T_s - T_\infty$, would only increase slightly.

PROBLEM 4.22

KNOWN: Long constantan wire butt-welded to a large copper block forming a thermocouple junction on the surface of the block.

FIND: (a) The measurement error $(T_j - T_o)$ for the thermocouple for prescribed conditions, and (b) Compute and plot $(T_j - T_o)$ for $h = 5, 10$ and $25 \text{ W/m}^2 \cdot \text{K}$ for block thermal conductivity $15 \leq k \leq 400 \text{ W/m} \cdot \text{K}$. When is it advantageous to use smaller diameter wire?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Thermocouple wire behaves as a fin with constant heat transfer coefficient, (3) Copper block has uniform temperature, except in the vicinity of the junction.

PROPERTIES: Table A-1, Copper (pure, 400 K), $k_b = 393 \text{ W/m} \cdot \text{K}$; Constantan (350 K), $k_t \approx 25 \text{ W/m} \cdot \text{K}$.

ANALYSIS: The thermocouple wire behaves as a long fin permitting heat to flow from the surface thereby depressing the sensing junction temperature below that of the block T_o . In the block, heat flows into the circular region of the wire-block interface; the thermal resistance to heat flow within the block is approximated as a disk of diameter D on a semi-infinite medium (k_b, T_o). The thermocouple-block combination can be represented by a thermal circuit as shown above. The thermal resistance of the fin follows from the heat rate expression for an infinite fin, $R_{fin} = (hPk_tA_c)^{-1/2}$.

From Table 4.1, the shape factor for the disk-on-a-semi-infinite medium is given as $S = 2D$ and hence $R_{block} = 1/k_bS = 1/2k_bD$. From the thermal circuit,

$$T_o - T_j = \frac{R_{block}}{R_{fin} + R_{block}} (T_o - T_\infty) = \frac{1.27}{1273 + 1.27} (125 - 25)^\circ \text{C} \approx 0.001(125 - 25)^\circ \text{C} = 0.1^\circ \text{C} \ll$$

with $P = \pi D$ and $A_c = \pi D^2/4$ and the thermal resistances as

$$R_{fin} = \left(10 \text{ W/m}^2 \cdot \text{K} (\pi/4) 25 \text{ W/m} \cdot \text{K} \times (1 \times 10^{-3} \text{ m})^3 \right)^{-1/2} = 1273 \text{ K/W}$$

$$R_{block} = (1/2) \times 393 \text{ W/m} \cdot \text{K} \times 10^{-3} \text{ m} = 1.27 \text{ K/W}.$$

(b) We keyed the above equations into the IHT workspace, performed a sweep on k_b for selected values of h and created the plot shown. When the block thermal conductivity is low, the error $(T_o - T_j)$ is larger, increasing with increasing convection coefficient. A smaller diameter wire will be advantageous for low values of k_b and higher values of h .

PROBLEM 4.23

KNOWN: Dimensions, shape factor, and thermal conductivity of square rod with drilled interior hole. Interior and exterior convection conditions.

FIND: Heat rate and surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) Uniform convection coefficients at inner and outer surfaces.

ANALYSIS: The heat loss can be expressed as

$$q = \frac{T_{\infty,1} - T_{\infty,2}}{R_{\text{conv},1} + R_{\text{cond}(2D)} + R_{\text{conv},2}}$$

where

$$R_{\text{conv},1} = (h_1 \pi D_1 L)^{-1} = (50 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.25 \text{ m} \times 2 \text{ m})^{-1} = 0.01273 \text{ K/W}$$

$$R_{\text{cond}(2D)} = (Sk)^{-1} = (8.59 \text{ m} \times 150 \text{ W/m} \cdot \text{K})^{-1} = 0.00078 \text{ K/W}$$

$$R_{\text{conv},2} = (h_2 \times 4wL)^{-1} = (4 \text{ W/m}^2 \cdot \text{K} \times 4 \text{ m} \times 1 \text{ m})^{-1} = 0.0625 \text{ K/W}$$

Hence,

$$q = \frac{(300 - 25)^\circ \text{C}}{0.076 \text{ K/W}} = 3.62 \text{ kW} \quad <$$

$$T_1 = T_{\infty,1} - qR_{\text{conv},1} = 300^\circ \text{C} - 46^\circ \text{C} = 254^\circ \text{C} \quad <$$

$$T_2 = T_{\infty,2} + qR_{\text{conv},2} = 25^\circ \text{C} + 226^\circ \text{C} = 251^\circ \text{C} \quad <$$

COMMENTS: The largest resistance is associated with convection at the outer surface, and the conduction resistance is much smaller than both convection resistances. Hence, $(T_2 - T_{\infty,2}) > (T_{\infty,1} - T_1) \gg (T_1 - T_2)$.

PROBLEM 4.24

KNOWN: Long fin of aluminum alloy with prescribed convection coefficient attached to different base materials (aluminum alloy or stainless steel) with and without thermal contact resistance $R''_{t,j}$ at the junction.

FIND: (a) Heat rate q_f and junction temperature T_j for base materials of aluminum and stainless steel, (b) Repeat calculations considering thermal contact resistance, $R''_{t,j}$, and (c) Plot as a function of h for the range $10 \leq h \leq 1000 \text{ W/m}^2 \cdot \text{K}$ for each base material.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Infinite fin.

PROPERTIES: (Given) Aluminum alloy, $k = 240 \text{ W/m} \cdot \text{K}$, Stainless steel, $k = 15 \text{ W/m} \cdot \text{K}$.

ANALYSIS: (a,b) From the thermal circuits, the heat rate and junction temperature are

$$q_f = \frac{T_b - T_\infty}{R_{\text{tot}}} = \frac{T_b - T_\infty}{R_b + R_{t,j} + R_f} \quad (1)$$

$$T_j = T_\infty + q_f R_f \quad (2)$$

and, with $P = \pi D$ and $A_c = \pi D^2/4$, from Tables 4.1 and 3.4 find

$$R_b = 1/Sk_b = 1/(2Dk_b) = (2 \times 0.005 \text{ m} \times k_b)^{-1}$$

$$R_{t,j} = R''_{t,j}/A_c = 3 \times 10^{-5} \text{ m}^2 \cdot \text{K} / \text{W} / \left[\pi (0.005 \text{ m})^2 / 4 \right] = 1.528 \text{ K/W}$$

$$R_f = (hPkA_c)^{-1/2} = \left[50 \text{ W/m}^2 \cdot \text{K} \pi^2 (0.005 \text{ m})^3 240 \text{ W/m} \cdot \text{K} / 4 \right]^{-1/2} = 16.4 \text{ K/W}$$

Base	$R_b \text{ (K/W)}$	Without $R''_{t,j}$		With $R''_{t,j}$	
		$q_f \text{ (W)}$	$T_j \text{ (}^\circ\text{C)}$	$q_f \text{ (W)}$	$T_j \text{ (}^\circ\text{C)}$
Al alloy	0.417	4.46	98.2	4.09	92.1
St. steel	6.667	3.26	78.4	3.05	75.1

(c) We used the *IHT Model for Extended Surfaces, Performance Calculations, Rectangular Pin Fin* to calculate q_f for $10 \leq h \leq 100 \text{ W/m}^2 \cdot \text{K}$ by replacing R''_{tc} (thermal resistance at fin base) by the sum of the contact and spreading resistances, $R''_{t,j} + R''_b$.

Continued...

PROBLEM 4.24 (Cont.)

COMMENTS: (1) From part (a), the aluminum alloy base material has negligible effect on the fin heat rate and depresses the base temperature by only $2^\circ C$. The effect of the stainless steel base material is substantial, reducing the heat rate by 27% and depressing the junction temperature by $25^\circ C$.

(2) The contact resistance reduces the heat rate and increases the temperature depression relatively more with the aluminum alloy base.

(3) From the plot of q_f vs. h , note that at low values of h , the heat rates are nearly the same for both materials since the fin is the dominant resistance. As h increases, the effect of R_b'' becomes more important.

PROBLEM 4.25

KNOWN: Igloo constructed in hemispheric shape sits on ice cap; igloo wall thickness and inside/outside convection coefficients (h_i , h_o) are prescribed.

FIND: (a) Inside air temperature $T_{\infty,i}$ when outside air temperature is $T_{\infty,o} = -40^\circ\text{C}$ assuming occupants provide 320 W within igloo, (b) Perform parameter sensitivity analysis to determine which variables have significant effect on T_i .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Convection coefficient is the same on floor and ceiling of igloo, (3) Floor and ceiling are at uniform temperatures, (4) Floor-ice cap resembles disk on semi-infinite medium, (5) One-dimensional conduction through igloo walls.

PROPERTIES: Ice and compacted snow (given): $k = 0.15 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) The thermal circuit representing the heat loss from the igloo to the outside air and through the floor to the ice cap is shown above. The heat loss is

$$q = \frac{T_{\infty,i} - T_{\infty,o}}{R_{cv,c} + R_{wall} + R_{cv,o}} + \frac{T_{\infty,i} - T_{ic}}{R_{cv,f} + R_{cap}}.$$

Convection, ceiling: $R_{cv,c} = \frac{2}{h_i (4\pi r_i^2)} = \frac{2}{6 \text{ W/m}^2 \cdot \text{K} \times 4\pi (1.8 \text{ m})^2} = 0.00819 \text{ K/W}$

Convection, outside: $R_{cv,o} = \frac{2}{h_o (4\pi r_o^2)} = \frac{2}{15 \text{ W/m}^2 \cdot \text{K} \times 4\pi (2.3 \text{ m})^2} = 0.00201 \text{ K/W}$

Convection, floor: $R_{cv,f} = \frac{1}{h_i (\pi r_i^2)} = \frac{1}{6 \text{ W/m}^2 \cdot \text{K} \times \pi (1.8 \text{ m})^2} = 0.01637 \text{ K/W}$

Conduction, wall: $R_{wall} = 2 \left[\frac{1}{4\pi k} \left(\frac{1}{r_i} - \frac{1}{r_o} \right) \right] = 2 \left[\frac{1}{4\pi \times 0.15 \text{ W/m}\cdot\text{K}} \left(\frac{1}{1.8} - \frac{1}{2.3} \right) \text{ m} \right] = 0.1281 \text{ K/W}$

Conduction, ice cap: $R_{cap} = \frac{1}{kS} = \frac{1}{4kr_i} = \frac{1}{4 \times 0.15 \text{ W/m}\cdot\text{K} \times 1.8 \text{ m}} = 0.9259 \text{ K/W}$

where S was determined from the shape factor of Table 4.1. Hence,

$$q = 320 \text{ W} = \frac{T_{\infty,i} - (-40)^\circ\text{C}}{(0.00819 + 0.1281 + 0.00201) \text{ K/W}} + \frac{T_{\infty,i} - (-20)^\circ\text{C}}{(0.01637 + 0.9259) \text{ K/W}}$$

$$320 \text{ W} = 7.231(T_{\infty,i} + 40) + 1.06(T_{\infty,i} + 20) \quad T_{\infty,i} = 1.2^\circ\text{C}.$$

<

PROBLEM 4.25 (Cont.)

(b) Begin the parameter sensitivity analysis to determine important variables which have a significant influence on the inside air temperature by examining the thermal resistances associated with the processes present in the system and represented by the network.

Process	Symbols		Value (K/W)
Convection, outside	$R_{cv,o}$	R21	0.0020
Conduction, wall	R_{wall}	R32	0.1281
Convection, ceiling	$R_{cv,c}$	R43	0.0082
Convection, floor	$R_{cv,f}$	R54	0.0164
Conduction, ice cap	R_{cap}	R65	0.9259

It follows that the convection resistances are negligible relative to the conduction resistance across the igloo wall. As such, only changes to the wall thickness will have an appreciable effect on the inside air temperature relative to the outside ambient air conditions. We don't want to make the igloo walls thinner and thereby allow the air temperature to dip below freezing for the prescribed environmental conditions.

Using the *IHT Thermal Resistance Network Model*, we used the circuit builder to construct the network and perform the energy balances to obtain the inside air temperature as a function of the outside convection coefficient for selected increased thicknesses of the wall.

COMMENTS: (1) From the plot, we can see that the influence of the outside air velocity which controls the outside convection coefficient h_o is negligible.

(2) The thickness of the igloo wall is the dominant thermal resistance controlling the inside air temperature.

PROBLEM 4.26

KNOWN: Chip dimensions, contact resistance and substrate material.

FIND: Maximum allowable chip power dissipation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat transfer from back of chip, (4) Uniform chip temperature, (5) Infinitely large substrate, (6) Negligible heat loss from the exposed surface of the substrate.

PROPERTIES: Table A.1, copper (25 °C): $k = 400 \text{ W/m}\cdot\text{K}$.

ANALYSIS: For the prescribed system, a thermal circuit may be drawn so that

where T_1 is the temperature of the substrate adjacent to the top of the chip. For an infinitely thin square object in an infinite medium we may apply Case 14 of Table 4.1 ($q_{ss}^* = 0.932$) resulting in

$$q = q_{ss}^* k A_s (T_1 - T_2) / L_c$$

where $L_c = (A_s / 4\pi)^{1/2}$; $A_s = 2W_c^2$

Recognizing that the bottom surfaces of the chip and substrate are insulated, the heat loss to the substrate may be determined by combining the preceding equations and dividing by 2 (to account for no heat losses from the bottom of the chip) resulting in

$$q = (2\pi)^{1/2} q_{ss}^* W_c k (T_1 - T_2) = \frac{1}{R_{t,sub}} (T_1 - T_2)$$

$$\text{or} \quad R_{t,sub} = \frac{1}{(2\pi)^{1/2} \times 0.932 \times 0.016 \text{ m} \times 400 \text{ W/m}\cdot\text{K}} = 0.067 \text{ K/W}$$

The thermal contact resistance is

Continued...

PROBLEM 4.26 (Cont.)

$$R_{t,c} = \frac{R''_{t,c}}{W_c^2} = \frac{5 \times 10^{-6} \text{ m}^2 \cdot \text{K/W}}{(0.016 \text{ m})^2} = 0.0195 \text{ K/W}$$

Therefore, the maximum allowable heat dissipation is

$$q_c = \frac{(85 - 25)^\circ\text{C}}{(0.0195 + 0.067) \text{ K/W}} = 694 \text{ W} \quad <$$

COMMENTS: (1) The copper block provides $694/276 = 2.5$ times greater allowable heat dissipation relative to the heat sink of Problem 3.136. (2) Use of a large substrate would not be practical in many applications due to its size and weight. (3) The actual allowable heat dissipation is greater than calculated here because of additional heat losses from the bottom of the block and chip that are not accounted for in the solution.

PROBLEM 4.27

KNOWN: Disc-shaped electronic devices dissipating 100 W mounted to aluminum alloy block with prescribed contact resistance.

FIND: (a) Temperature device will reach when block is at 27°C assuming all the power generated by the device is transferred by conduction to the block and (b) For the operating temperature found in part (a), the permissible operating power with a 30-pin fin heat sink.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Device is at uniform temperature, T_1 , (3) Block behaves as semi-infinite medium.

PROPERTIES: Table A.1, Aluminum alloy 2024 (300 K): $k = 177 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) The thermal circuit for the conduction heat flow between the device and the block shown in the above Schematic where R_e is the thermal contact resistance due to the epoxy-filled interface,

$$R_e = R''_{t,c} / A_c = R''_{t,c} / \left(\pi D^2 / 4 \right)$$

$$R_e = 5 \times 10^{-5} \text{ K}\cdot\text{m}^2/\text{W} / \left(\pi (0.020 \text{ m})^2 \right) / 4 = 0.159 \text{ K/W}$$

The thermal resistance between the device and the block is given in terms of the conduction shape factor, Table 4.1, as

$$R_b = 1/Sk = 1/(2Dk)$$

$$R_b = 1/(2 \times 0.020 \text{ m} \times 177 \text{ W/m}\cdot\text{K}) = 0.141 \text{ K/W}$$

From the thermal circuit,

$$T_1 = T_2 + q_d (R_b + R_e)$$

$$T_1 = 27^\circ\text{C} + 100 \text{ W} (0.141 + 0.159) \text{ K/W}$$

$$T_1 = 27^\circ\text{C} + 30^\circ\text{C} = 57^\circ\text{C}$$

<

(b) The schematic below shows the device with the 30-pin fin heat sink with fins and base material of copper ($k = 400 \text{ W/m}\cdot\text{K}$). The airstream temperature is 27°C and the convection coefficient is 1000 $\text{W/m}^2\cdot\text{K}$.

Continued...

PROBLEM 4.27 (Cont.)

The thermal circuit for this system has two paths for the device power: to the block by conduction, q_{cd} , and to the ambient air by conduction to the fin array, q_{cv} ,

$$q_d = \frac{T_1 - T_2}{R_b + R_e} + \frac{T_1 - T_\infty}{R_e + R_c + R_{fin}} \quad (3)$$

where the thermal resistance of the fin base material is

$$R_c = \frac{L_c}{k_c A_c} = \frac{0.005 \text{ m}}{400 \text{ W/m} \cdot \text{K} \left(\pi (0.02^2 / 4) \text{ m}^2 \right)} = 0.03979 \text{ K/W} \quad (4)$$

and R_{fin} represents the thermal resistance of the fin array (see Section 3.6.5),

$$R_{fin} = R_{t,o} = \frac{1}{\eta_o h A_t} \quad (5, 3.103)$$

$$\eta_o = 1 - \frac{N A_f}{A_t} (1 - \eta_f) \quad (6, 3.102)$$

where the fin and prime surface area is

$$A_t = N A_f + A_b \quad (3.99)$$

$$A_t = N (\pi D_f L) + \left[\pi D_d^2 / 4 - N (\pi D_f^2 / 4) \right]$$

where A_f is the fin surface area, D_d is the device diameter and D_f is the fin diameter.

$$A_t = 30 (\pi \times 0.0015 \text{ m} \times 0.015 \text{ m}) + \left[\pi (0.020 \text{ m})^2 / 4 - 30 (\pi (0.0015 \text{ m})^2 / 4) \right]$$

$$A_t = 0.00212 \text{ m}^2 + 0.0002611 \text{ m}^2 = 0.00238 \text{ m}^2$$

Using the *IHT Model, Extended Surfaces, Performance Calculations, Rectangular Pin Fin*, find the fin efficiency as

$$\eta_f = 0.6769 \quad (7)$$

Continued...

PROBLEM 4.27 (Cont.)

Substituting numerical values into Equation (6), find

$$\eta_o = 1 - \frac{30 \times \pi \times 0.0015 \text{ m} \times 0.015 \text{ m}}{0.00238 \text{ m}^2} (1 - 0.6769)$$

$$\eta_o = 0.712$$

and the fin array thermal resistance is

$$R_{\text{fin}} = \frac{1}{0.712 \times 1000 \text{ W/m}^2 \cdot \text{K} \times 0.00238 \text{ m}^2} = 0.590 \text{ K/W}$$

Returning to Eq. (3), with $T_1 = 57^\circ\text{C}$ from part (a), the permissible heat rate is

$$q_d = \frac{(57 - 27)^\circ\text{C}}{(0.141 + 0.159) \text{ K/W}} + \frac{(57 - 27)^\circ\text{C}}{(0.159 + 0.03979 + 0.590) \text{ K/W}}$$

$$q_d = 100 \text{ W} + 38 \text{ W} = 138 \text{ W}$$

<

COMMENTS: In calculating the fin efficiency, η_f , using the IHT Model it is not necessary to know the base temperature as η_f depends only upon geometric parameters, thermal conductivity and the convection coefficient.

PROBLEM 4.28

KNOWN: Dimensions and surface temperatures of a square channel. Number of chips mounted on outer surface and chip thermal contact resistance.

FIND: Heat dissipation per chip and chip temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady state, (2) Approximately uniform channel inner and outer surface temperatures, (3) Two-dimensional conduction through channel wall (negligible end-wall effects), (4) Constant thermal conductivity.

ANALYSIS: The total heat rate is determined by the two-dimensional conduction resistance of the channel wall, $q = (T_2 - T_1)/R_{t,cond(2D)}$, with the resistance determined by using Equation 4.21 with Case 11 of Table 4.1. For $W/w = 1.6 > 1.4$

$$R_{t,cond(2D)} = \frac{0.930 \ln(W/w) - 0.050}{2\pi L k} = \frac{0.387}{2\pi (0.160\text{m}) 240 \text{ W/m}\cdot\text{K}} = 0.00160 \text{ K/W}$$

The heat rate per chip is then

$$q_c = \frac{T_2 - T_1}{N R_{t,cond(2D)}} = \frac{(50 - 20)^\circ\text{C}}{120(0.0016 \text{ K/W})} = 156.3 \text{ W} \quad <$$

and, with $q_c = (T_c - T_2)/R_{t,c}$, the chip temperature is

$$T_c = T_2 + R_{t,c} q_c = 50^\circ\text{C} + (0.2 \text{ K/W}) 156.3 \text{ W} = 81.3^\circ\text{C} \quad <$$

COMMENTS: (1) By acting to *spread* heat flow lines away from a chip, the channel wall provides an excellent *heat sink* for dissipating heat generated by the chip. However, recognize that, in practice, there will be temperature variations on the inner and outer surfaces of the channel, and if the prescribed values of T_1 and T_2 represent minimum and maximum inner and outer surface temperatures, respectively, the rate is overestimated by the foregoing analysis. (2) The shape factor may also be determined by combining the expression for a plane wall with the result of Case 8 (Table 4.1). With $S = [4(wL)/((W-w)/2)] + 4(0.54 L) = 2.479 \text{ m}$, $R_{t,cond(2D)} = 1/(Sk) = 0.00168 \text{ K/W}$.

PROBLEM 4.29

KNOWN: Dimensions and thermal conductivity of concrete duct. Convection conditions of ambient air. Inlet temperature of water flow through the duct.

FIND: (a) Heat loss per duct length near inlet, (b) Minimum allowable flow rate corresponding to maximum allowable temperature rise of water.

SCHEMATIC:

ASSUMPTIONS: (1) Steady state, (2) Negligible water-side convection resistance, pipe wall conduction resistance, and pipe/concrete contact resistance (temperature at inner surface of concrete corresponds to that of water), (3) Constant properties, (4) Negligible flow work and kinetic and potential energy changes.

ANALYSIS: (a) From the thermal circuit, the heat loss per unit length near the entrance is

$$q' = \frac{T_i - T_\infty}{R'_{\text{cond}}(2D) + R'_{\text{conv}}} = \frac{T_i - T_\infty}{\frac{\ln(1.08w/D)}{2\pi k} + \frac{1}{h(4w)}}$$

where $R'_{\text{cond}}(2D)$ is obtained by using the shape factor of Case 6 from Table 4.1 with Eq. (4.21).

Hence,

$$q' = \frac{(90 - 0)^\circ\text{C}}{\frac{\ln(1.08 \times 0.3\text{m} / 0.15\text{m})}{2\pi(1.4\text{ W/m}\cdot\text{K})} + \frac{1}{25\text{ W/m}^2\cdot\text{K}(1.2\text{m})}} = \frac{90^\circ\text{C}}{(0.0876 + 0.0333)\text{ K}\cdot\text{m/W}} = 745\text{ W/m} \quad <$$

(b) From Eq. (1.11d), with $q = q'L$ and $(T_i - T_o) = 5^\circ\text{C}$,

$$\dot{m} = \frac{q'L}{u_i - u_o} = \frac{q'L}{c(T_i - T_o)} = \frac{745\text{ W/m}(100\text{m})}{4207\text{ J/kg}\cdot\text{K}(5^\circ\text{C})} = 3.54\text{ kg/s} \quad <$$

COMMENTS: The small reduction in the temperature of the water as it flows from inlet to outlet induces a slight departure from two-dimensional conditions and a small reduction in the heat rate per unit length. A slightly conservative value (upper estimate) of \dot{m} is therefore obtained in part (b).

PROBLEM 4.30

KNOWN: Dimensions and thermal conductivities of a heater and a finned sleeve. Convection conditions on the sleeve surface.

FIND: (a) Heat rate per unit length, (b) Generation rate and centerline temperature of heater, (c) Effect of fin parameters on heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady state, (2) Constant properties, (3) Negligible contact resistance between heater and sleeve, (4) Uniform convection coefficient at outer surfaces of sleeve, (5) Uniform heat generation, (6) Negligible radiation.

ANALYSIS: (a) From the thermal circuit, the desired heat rate is

$$q' = \frac{T_s - T_\infty}{R'_{\text{cond}}(2D) + R'_{t,o}} = \frac{T_s - T_\infty}{R'_{\text{tot}}}$$

The two-dimensional conduction resistance, may be estimated from Eq. (4.21) and Case 6 of Table 4.2

$$R'_{\text{cond}}(2D) = \frac{1}{S'k_s} = \frac{\ln(1.08w/D)}{2\pi k_s} = \frac{\ln(2.16)}{2\pi(240 \text{ W/m}\cdot\text{K})} = 5.11 \times 10^{-4} \text{ m}\cdot\text{K/W}$$

The thermal resistance of the fin array is given by Equation (3.103), where η_o and A_t are given by Equations (3.102) and (3.99) and η_f is given by Equation (3.89). With $L_c = L + t/2 = 0.022 \text{ m}$, $m = (2h/k_s t)^{1/2} = 32.3 \text{ m}^{-1}$ and $mL_c = 0.710$,

$$\eta_f = \frac{\tanh mL_c}{mL_c} = \frac{0.61}{0.71} = 0.86$$

$$A'_t = NA'_f + A'_b = N(2L + t) + (4w - Nt) = 0.704\text{m} + 0.096\text{m} = 0.800\text{m}$$

$$\eta_o = 1 - \frac{NA'_f}{A'_t}(1 - \eta_f) = 1 - \frac{0.704\text{m}}{0.800\text{m}}(0.14) = 0.88$$

$$R'_{t,o} = (\eta_o h A'_t)^{-1} = (0.88 \times 500 \text{ W/m}^2 \cdot \text{K} \times 0.80\text{m})^{-1} = 2.84 \times 10^{-3} \text{ m}\cdot\text{K/W}$$

$$q' = \frac{(300 - 50)^\circ\text{C}}{(5.11 \times 10^{-4} + 2.84 \times 10^{-3}) \text{ m}\cdot\text{K/W}} = 74,600 \text{ W/m}$$

<

Continued...

PROBLEM 4.30 (Cont.)

(b) Equation (3.55) may be used to determine \dot{q} , if h is replaced by an overall coefficient based on the surface area of the heater. From Equation (3.32),

$$U_s A'_s = U_s \pi D = (R'_{\text{tot}})^{-1} = \left(3.35 \times 10^{-3} \text{ m} \cdot \text{K} / \text{W} \right)^{-1} = 298 \text{ W} / \text{m} \cdot \text{K}$$

$$U_s = 298 \text{ W} / \text{m} \cdot \text{K} / (\pi \times 0.02 \text{ m}) = 4750 \text{ W} / \text{m}^2 \cdot \text{K}$$

$$\dot{q} = 4 U_s (T_s - T_\infty) / D = 4 \left(4750 \text{ W} / \text{m}^2 \cdot \text{K} \right) (250^\circ \text{C}) / 0.02 \text{ m} = 2.38 \times 10^8 \text{ W} / \text{m}^3 <$$

From Equation (3.53) the centerline temperature is

$$T(0) = \frac{\dot{q} (D/2)^2}{4 k_h} + T_s = \frac{2.38 \times 10^8 \text{ W} / \text{m}^3 (0.01 \text{ m})^2}{4 (400 \text{ W} / \text{m} \cdot \text{K})} + 300^\circ \text{C} = 315^\circ \text{C} <$$

(c) Subject to the prescribed constraints, the following results have been obtained for parameter variations corresponding to $16 \leq N \leq 40$, $2 \leq t \leq 8 \text{ mm}$ and $20 \leq L \leq 40 \text{ mm}$.

<u>N</u>	<u>t(mm)</u>	<u>L(mm)</u>	<u>η_f</u>	<u>$q' (\text{W} / \text{m})$</u>
16	4	20	0.86	74,400
16	8	20	0.91	77,000
28	4	20	0.86	107,900
32	3	20	0.83	115,200
40	2	20	0.78	127,800
40	2	40	0.51	151,300

Clearly there is little benefit to simply increasing t , since there is no change in A'_t and only a marginal increase in η_f . However, due to an attendant increase in A'_t , there is significant benefit to increasing N for fixed t (no change in η_f) and additional benefit in concurrently increasing N while decreasing t . In this case the effect of increasing A'_t exceeds that of decreasing η_f . The same is true for increasing L , although there is an upper limit at which diminishing returns would be reached. The upper limit to L could also be influenced by manufacturing constraints.

COMMENTS: Without the sleeve, the heat rate would be $q' = \pi D h (T_s - T_\infty) = 7850 \text{ W} / \text{m}$, which is well below that achieved by using the increased surface area afforded by the sleeve.

PROBLEM 4.31

KNOWN: Dimensions of chip array. Conductivity of substrate. Convection conditions. Contact resistance. Expression for resistance of spreader plate. Maximum chip temperature.

FIND: Maximum chip heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant thermal conductivity, (3) Negligible radiation, (4) All heat transfer is by convection from the chip and the substrate surface (negligible heat transfer from bottom or sides of substrate).

ANALYSIS: From the thermal circuit,

$$q = q_h + q_{\text{sp}} = \frac{T_h - T_\infty}{R_{h,\text{cnv}}} + \frac{T_h - T_\infty}{R_{t(\text{sp})} + R_{t,c} + R_{\text{sp,cnv}}}$$

$$R_{h,\text{cnv}} = (h A_{s,h})^{-1} = (h L_h^2)^{-1} = \left[100 \text{ W/m}^2 \cdot \text{K} (0.005 \text{ m})^2 \right]^{-1} = 400 \text{ K/W}$$

$$R_{t(\text{sp})} = \frac{1 - 1.410 A_r + 0.344 A_r^3 + 0.043 A_r^5 + 0.034 A_r^7}{4 k_{\text{sub}} L_h} = \frac{1 - 0.353 + 0.005 + 0 + 0}{4 (80 \text{ W/m} \cdot \text{K}) (0.005 \text{ m})} = 0.408 \text{ K/W}$$

$$R_{t,c} = \frac{R''_{t,c}}{L_h^2} = \frac{0.5 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}}{(0.005 \text{ m})^2} = 2.000 \text{ K/W}$$

$$R_{\text{sp,cnv}} = \left[h (A_{\text{sub}} - A_{s,h}) \right]^{-1} = \left[100 \text{ W/m}^2 \cdot \text{K} \left((0.010 \text{ m})^2 - (0.005 \text{ m})^2 \right) \right]^{-1} = 133.3 \text{ K/W}$$

$$q = \frac{70^\circ\text{C}}{400 \text{ K/W}} + \frac{70^\circ\text{C}}{(0.408 + 2 + 133.3) \text{ K/W}} = 0.18 \text{ W} + 0.52 \text{ W} = 0.70 \text{ W} \quad <$$

COMMENTS: (1) The thermal resistances of the substrate and the chip/substrate interface are much less than the substrate convection resistance. Hence, the heat rate is increased almost in proportion to the additional surface area afforded by the substrate. An increase in the spacing between chips (S_h) would increase q correspondingly.

(2) In the limit $A_r \rightarrow 0$, $R_{t(\text{sp})}$ reduces to $2\pi^{1/2} k_{\text{sub}} D_h$ for a circular heat source and $4k_{\text{sub}} L_h$ for a square source.

PROBLEM 4.32

KNOWN: Internal corner of a two-dimensional system with prescribed convection boundary conditions.

FIND: Finite-difference equations for these situations: (a) Horizontal boundary is perfectly insulated and vertical boundary is subjected to a convection process (T_∞, h), (b) Both boundaries are perfectly insulated; compare result with Eq. 4.41.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) No internal generation.

ANALYSIS: Consider the nodal network shown above and also as Case 2, Table 4.2. Having defined the control volume – the shaded area of unit thickness normal to the page – next identify the heat transfer processes. Finally, perform an energy balance wherein the processes are expressed using appropriate rate equations.

(a) With the horizontal boundary insulated and the vertical boundary subjected to a convection process, the energy balance results in the following finite-difference equation:

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} = 0 \quad q_1 + q_2 + q_3 + q_4 + q_5 + q_6 = 0 \\ k(\Delta y \cdot 1) \frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k \left[\frac{\Delta x}{2} \cdot 1 \right] \frac{T_{m,n-1} - T_{m,n}}{\Delta y} + h \left[\frac{\Delta y}{2} \cdot 1 \right] (T_\infty - T_{m,n}) \\ + 0 + k \left[\frac{\Delta y}{2} \cdot 1 \right] \frac{T_{m+1,n} - T_{m,n}}{\Delta x} + k(\Delta x \cdot 1) \frac{T_{m,n+1} - T_{m,n}}{\Delta y} = 0. \end{aligned}$$

Letting $\Delta x = \Delta y$, and regrouping, find

$$2(T_{m-1,n} + T_{m,n+1}) + (T_{m+1,n} + T_{m,n-1}) + \frac{h\Delta x}{k} T_\infty - \left[6 + \frac{h\Delta x}{k} \right] T_{m,n} = 0. \quad <$$

(b) With both boundaries insulated, the energy balance would have $q_3 = q_4 = 0$. The same result would be obtained by letting $h = 0$ in the previous result. Hence,

$$2(T_{m-1,n} + T_{m,n+1}) + (T_{m+1,n} + T_{m,n-1}) - 6 T_{m,n} = 0. \quad <$$

Note that this expression compares exactly with Equation 4.41 when $h = 0$, which corresponds to insulated boundaries.

PROBLEM 4.33

KNOWN: Plane surface of two-dimensional system.

FIND: The finite-difference equation for nodal point on this boundary when (a) insulated; compare result with Eq. 4.42, and when (b) subjected to a constant heat flux.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction with no generation, (2) Constant properties, (3) Boundary is adiabatic.

ANALYSIS: (a) Performing an energy balance on the control volume, $(\Delta x/2) \cdot \Delta y$, and using the conduction rate equation, it follows that

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_1 + q_2 + q_3 = 0 \quad (1,2)$$

$$k(\Delta y \cdot 1) \frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k \left[\frac{\Delta x}{2} \cdot 1 \right] \frac{T_{m,n-1} - T_{m,n}}{\Delta y} + k \left[\frac{\Delta x}{2} \cdot 1 \right] \frac{T_{m,n+1} - T_{m,n}}{\Delta y} = 0. \quad (3)$$

Note that there is no heat rate across the control volume surface at the insulated boundary. Recognizing that $\Delta x = \Delta y$, the above expression reduces to the form

$$2T_{m-1,n} + T_{m,n-1} + T_{m,n+1} - 4T_{m,n} = 0. \quad (4) <$$

The Eq. 4.42 of Table 4.2 considers the same configuration but with the boundary subjected to a convection process. That is,

$$\left(2T_{m-1,n} + T_{m,n-1} + T_{m,n+1} \right) + \frac{2h\Delta x}{k} T_{\infty} - 2 \left[\frac{h\Delta x}{k} + 2 \right] T_{m,n} = 0. \quad (5)$$

Note that, if the boundary is insulated, $h = 0$ and Eq. 4.42 reduces to Eq. (4).

(b) If the surface is exposed to a constant heat flux, q_0'' , the energy balance has the form

$q_1 + q_2 + q_3 + q_0'' \cdot \Delta y = 0$ and the finite difference equation becomes

$$2T_{m-1,n} + T_{m,n-1} + T_{m,n+1} - 4T_{m,n} = -\frac{2q_0''\Delta x}{k}. \quad <$$

COMMENTS: Equation (4) can be obtained by using the “interior node” finite-difference equation, Eq. 4.29, where the insulated boundary is treated as a symmetry plane as shown below.

PROBLEM 4.34

KNOWN: External corner of a two-dimensional system whose boundaries are subjected to prescribed conditions.

FIND: Finite-difference equations for these situations: (a) Upper boundary is perfectly insulated and side boundary is subjected to a convection process, (b) Both boundaries are perfectly insulated; compare result with Eq. 4.43.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) No internal generation.

ANALYSIS: Consider the nodal point configuration shown in the schematic and also as Case 4, Table 4.2. The control volume about the node – shaded area above of unit thickness normal to the page – has dimensions, $(\Delta x/2)(\Delta y/2) \cdot 1$. The heat transfer processes at the surface of the CV are identified as $q_1, q_2 \dots$. Perform an energy balance wherein the processes are expressed using the appropriate rate equations.

(a) With the upper boundary insulated and the side boundary subjected to a convection process, the energy balance has the form

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_1 + q_2 + q_3 + q_4 = 0 \quad (1,2)$$

$$k \left[\frac{\Delta y}{2} \cdot 1 \right] \frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k \left[\frac{\Delta x}{2} \cdot 1 \right] \frac{T_{m,n-1} - T_{m,n}}{\Delta y} + h \left[\frac{\Delta y}{2} \cdot 1 \right] (T_{\infty} - T_{m,n}) + 0 = 0.$$

Letting $\Delta x = \Delta y$, and regrouping, find

$$T_{m,n-1} + T_{m-1,n} + \frac{h\Delta x}{k} T_{\infty} - 2 \left[\frac{1}{2} \frac{h\Delta x}{k} + 1 \right] T_{m,n} = 0. \quad (3) <$$

(b) With both boundaries insulated, the energy balance of Eq. (2) would have $q_3 = q_4 = 0$. The same result would be obtained by letting $h = 0$ in the finite-difference equation, Eq. (3). The result is

$$T_{m,n-1} + T_{m-1,n} - 2T_{m,n} = 0. \quad <$$

Note that this expression is identical to Eq. 4.43 when $h = 0$, in which case both boundaries are insulated.

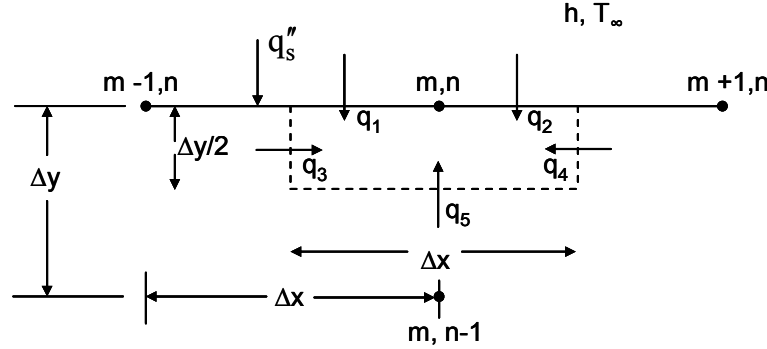

COMMENTS: Note the convenience resulting from formulating the energy balance by *assuming* that all the heat flow is *into the node*.

PROBLEM 4.35

KNOWN: Boundary conditions that change from specified heat flux to convection.

FIND: The finite difference equation for the node at the point where the boundary condition changes.

SCHEMATIC:

ASSUMPTIONS: (1) Two dimensional, steady-state conduction with no generation, (2) Constant properties.

ANALYSIS: Performing an energy balance on the control volume $\Delta x \cdot \Delta y/2$,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_1 + q_2 + q_3 + q_4 + q_5 = 0$$

Expressing q_1 in terms of the specified heat flux, q_2 in terms of the known heat transfer coefficient and environment temperature, and the remaining heat rates using the conduction rate equation,

$$q_1 = q_s'' \frac{\Delta x}{2} \cdot 1$$

$$q_2 = h(T_\infty - T_{m,n}) \frac{\Delta x}{2} \cdot 1$$

$$q_3 = \frac{k(T_{m-1,n} - T_{m,n})}{\Delta x} \frac{\Delta y}{2} \cdot 1$$

$$q_4 = \frac{k(T_{m+1,n} - T_{m,n})}{\Delta x} \frac{\Delta y}{2} \cdot 1$$

$$q_5 = \frac{k(T_{m,n-1} - T_{m,n})}{\Delta y} \Delta x \cdot 1$$

Letting $\Delta x = \Delta y$, substituting these expressions into the energy balance, and rearranging yields

$$T_{m-1,n} + T_{m+1,n} + 2T_{m,n-1} - \left[4 + \frac{h\Delta x}{k} \right] T_{m,n} + \frac{h\Delta x}{k} T_\infty + \frac{q_s''\Delta x}{k} = 0$$

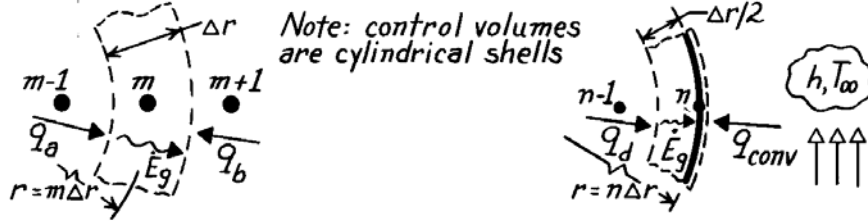

<

PROBLEM 4.36

KNOWN: Conduction in a one-dimensional (radial) *cylindrical* coordinate system with volumetric generation.

FIND: Finite-difference equation for (a) Interior node, m , and (b) Surface node, n , with convection.

SCHEMATIC:

(a) Interior node, m

(b) Surface node with convection, n

ASSUMPTIONS: (1) Steady-state, one-dimensional (radial) conduction in *cylindrical* coordinates, (2) Constant properties.

ANALYSIS: (a) The network has nodes spaced at equal Δr increments with $m = 0$ at the center; hence, $r = m\Delta r$ (or $n\Delta r$). The control volume is $V = 2\pi r \cdot \Delta r \cdot \ell = 2\pi(m\Delta r)\Delta r \cdot \ell$. The energy balance is $\dot{E}_{in} + \dot{E}_g = q_a + q_b + \dot{q}V = 0$

$$k \left[2\pi \left[r - \frac{\Delta r}{2} \right] \ell \right] \frac{T_{m-1} - T_m}{\Delta r} + k \left[2\pi \left[r + \frac{\Delta r}{2} \right] \ell \right] \frac{T_{m+1} - T_m}{\Delta r} + \dot{q} [2\pi(m\Delta r)\Delta r \ell] = 0.$$

Recognizing that $r = m\Delta r$, canceling like terms, and regrouping find

$$\left[m - \frac{1}{2} \right] T_{m-1} + \left[m + \frac{1}{2} \right] T_{m+1} - 2mT_m + \frac{\dot{q}m\Delta r^2}{k} = 0. \quad <$$

(b) The control volume for the surface node is $V = 2\pi r \cdot (\Delta r/2) \cdot \ell$. The energy balance is

$\dot{E}_{in} + \dot{E}_g = q_d + q_{conv} + \dot{q}V = 0$. Use Fourier's law to express q_d and Newton's law of cooling for q_{conv} to obtain

$$k \left[2\pi \left[r - \frac{\Delta r}{2} \right] \ell \right] \frac{T_{n-1} - T_n}{\Delta r} + h [2\pi r \ell] (T_\infty - T_n) + \dot{q} \left[2\pi(n\Delta r) \frac{\Delta r}{2} \ell \right] = 0.$$

Let $r = n\Delta r$, cancel like terms and regroup to find

$$\left[n - \frac{1}{2} \right] T_{n-1} - \left[\left[n - \frac{1}{2} \right] + \frac{hn\Delta r}{k} \right] T_n + \frac{\dot{q}n\Delta r^2}{2k} + \frac{hn\Delta r}{k} T_\infty = 0. \quad <$$

COMMENTS: (1) Note that when m or n becomes very large compared to $1/2$, the finite-difference equation becomes independent of m or n . Then the cylindrical system approximates a rectangular one.

(2) The finite-difference equation for the center node ($m = 0$) needs to be treated as a special case. The control volume is

$V = \pi (\Delta r/2)^2 \ell$ and the energy balance is

$$\dot{E}_{in} + \dot{E}_g = q_a + \dot{q}V = k \left[2\pi \left[\frac{\Delta r}{2} \right] \ell \right] \frac{T_1 - T_0}{\Delta r} + \dot{q} \left[\pi \left[\frac{\Delta r}{2} \right]^2 \ell \right] = 0.$$

Regrouping, the finite-difference equation is $-T_0 + T_1 + \frac{\dot{q}\Delta r^2}{4k} = 0$.

PROBLEM 4.37

KNOWN: Two-dimensional cylindrical configuration with prescribed radial (Δr) and angular ($\Delta\phi$) spacings of nodes.

FIND: Finite-difference equations for nodes 2, 3 and 1.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction in cylindrical coordinates (r, ϕ), (3) Constant properties.

ANALYSIS: The method of solution is to define the appropriate control volume for each node, to identify relevant processes and then to perform an energy balance.

(a) Node 2. This is an *interior* node with control volume as shown above. The energy balance is $\dot{E}_{in} = q'_a + q'_b + q'_c + q'_d = 0$. Using Fourier's law for each process, find

$$k \left[\left[r_1 + \frac{3}{2} \Delta r \right] \Delta\phi \right] \frac{(T_5 - T_2)}{\Delta r} + k(\Delta r) \frac{(T_3 - T_2)}{(r_1 + \Delta r) \Delta\phi} + k \left[\left[r_1 + \frac{1}{2} \Delta r \right] \Delta\phi \right] \frac{(T_1 - T_2)}{\Delta r} + k(\Delta r) \frac{(T_1 - T_2)}{(r_1 + \Delta r) \Delta\phi} = 0.$$

Canceling terms and regrouping yields,

$$-2 \left[(r_1 + \Delta r) + \frac{(\Delta r)^2}{(\Delta\phi)^2} \frac{1}{(r_1 + \Delta r)} \right] T_2 + \left[r_1 + \frac{3}{2} \Delta r \right] T_5 + \frac{(\Delta r)^2}{(r_1 + \Delta r)(\Delta\phi)^2} (T_3 + T_1) + \left[r_1 + \frac{1}{2} \Delta r \right] T_1 = 0.$$

(b) Node 3. The adiabatic surface behaves as a symmetry surface. We can utilize the result of Part (a) to write the finite-difference equation by inspection as

$$-2 \left[(r_1 + \Delta r) + \frac{(\Delta r)^2}{(\Delta\phi)^2} \frac{1}{(r_1 + \Delta r)} \right] T_3 + \left[r_1 + \frac{3}{2} \Delta r \right] T_6 + \frac{2(\Delta r)^2}{(r_1 + \Delta r)(\Delta\phi)^2} \cdot T_2 + \left[r_1 + \frac{1}{2} \Delta r \right] T_1 = 0.$$

(c) Node 1. The energy balance is $q'_a + q'_b + q'_c + q'_d = 0$. Substituting,

$$k \left[\left[r_1 + \frac{3}{2} \Delta r \right] \frac{\Delta\phi}{2} \right] \frac{(T_4 - T_1)}{\Delta r} + k(\Delta r) \frac{(T_2 - T_1)}{(r_1 + \Delta r) \Delta\phi} + k \left[\left[r_1 + \frac{1}{2} \Delta r \right] \frac{\Delta\phi}{2} \right] \frac{(T_1 - T_1)}{\Delta r} + h(\Delta r)(T_\infty - T_1) = 0$$

This expression could now be rearranged.

<

PROBLEM 4.38

KNOWN: Heat generation and thermal boundary conditions of bus bar. Finite-difference grid.

FIND: Finite-difference equations for selected nodes.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: (a) Performing an energy balance on the control volume, $(\Delta x/2)(\Delta y/2) \cdot 1$, find the FDE for node 1,

$$\begin{aligned} & \frac{T_0 - T_1}{R_{t,c}'' / (\Delta y/2) \cdot 1} + h_u \left(\frac{\Delta x}{2} \cdot 1 \right) (T_\infty - T_1) + \frac{k(\Delta y/2 \cdot 1)}{\Delta x} (T_2 - T_1) \\ & + \frac{k(\Delta x/2 \cdot 1)}{\Delta y} (T_6 - T_1) + \dot{q} [(\Delta x/2)(\Delta y/2) \cdot 1] = 0 \\ & \left(\Delta x / k R_{t,c}'' \right) T_0 + (h_u \Delta x / k) T_\infty + T_2 + T_6 \\ & + \dot{q} (\Delta x)^2 / 2k - \left[\left(\Delta x / k R_{t,c}'' \right) + (h_u \Delta x / k) + 2 \right] T_1 = 0. \end{aligned} \quad <$$

(b) Performing an energy balance on the control volume, $(\Delta x)(\Delta y/2) \cdot 1$, find the FDE for node 13,

$$\begin{aligned} & h_l (\Delta x \cdot 1) (T_\infty - T_{13}) + (k/\Delta x) (\Delta y/2 \cdot 1) (T_{12} - T_{13}) \\ & + (k/\Delta y) (\Delta x \cdot 1) (T_8 - T_{13}) + (k/\Delta x) (\Delta y/2 \cdot 1) (T_{14} - T_{13}) + \dot{q} (\Delta x \cdot \Delta y/2 \cdot 1) = 0 \\ & (h_l \Delta x / k) T_\infty + 1/2 (T_{12} + 2T_8 + T_{14}) + \dot{q} (\Delta x)^2 / 2k - (h_l \Delta x / k + 2) T_{13} = 0. \end{aligned} \quad <$$

COMMENTS: For fixed T_0 and T_∞ , the relative amounts of heat transfer to the air and heat sink are determined by the values of h and $R_{t,c}''$.

PROBLEM 4.39

KNOWN: Nodal point configurations corresponding to a diagonal surface boundary subjected to a convection process and to the tip of a machine tool subjected to constant heat flux and convection cooling.

FIND: Finite-difference equations for the node m,n in the two situations shown.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, 2-D conduction, (2) Constant properties.

ANALYSIS: (a) The control volume about node m,n has triangular shape with sides Δx and Δy while the diagonal (surface) length is $\sqrt{2} \Delta x$. The heat rates associated with the control volume are due to conduction, q_1 and q_2 , and to convection, q_c . Performing an energy balance, find

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_1 + q_2 + q_c = 0$$

$$k(\Delta x \cdot 1) \frac{T_{m,n-1} - T_{m,n}}{\Delta y} + k(\Delta y \cdot 1) \frac{T_{m+1,n} - T_{m,n}}{\Delta x} + h(\sqrt{2} \Delta x \cdot 1)(T_{\infty} - T_{m,n}) = 0.$$

Note that we have considered the solid to have unit depth normal to the page. Recognizing that $\Delta x = \Delta y$, dividing each term by k and regrouping, find

$$T_{m,n-1} + T_{m+1,n} + \sqrt{2} \cdot \frac{h\Delta x}{k} T_{\infty} - \left[2 + \sqrt{2} \cdot \frac{h\Delta x}{k} \right] T_{m,n} = 0. \quad <$$

(b) The control volume about node m,n has triangular shape with sides $\Delta x/2$ and $\Delta y/2$ while the lower diagonal surface length is $\sqrt{2}(\Delta x/2)$. The heat rates associated with the control volume are due to the constant heat flux, q_a , to conduction, q_b , and to the convection process, q_c . Perform an energy balance,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_a + q_b + q_c = 0$$

$$q_o'' \cdot \left[\frac{\Delta x}{2} \cdot 1 \right] + k \cdot \left[\frac{\Delta y}{2} \cdot 1 \right] \frac{T_{m+1,n} - T_{m,n}}{\Delta x} + h \cdot \left[\sqrt{2} \cdot \frac{\Delta x}{2} \right] (T_{\infty} - T_{m,n}) = 0.$$

Recognizing that $\Delta x = \Delta y$, dividing each term by $k/2$ and regrouping, find

$$T_{m+1,n} + \sqrt{2} \cdot \frac{h\Delta x}{k} \cdot T_{\infty} + q_o'' \cdot \frac{\Delta x}{k} - \left(1 + \sqrt{2} \cdot \frac{h\Delta x}{k} \right) T_{m,n} = 0. \quad <$$

COMMENTS: Note the appearance of the term $h\Delta x/k$ in both results, which is a dimensionless parameter (the *Biot number*) characterizing the relative effects of convection and conduction.

PROBLEM 4.40

KNOWN: Nodal point on boundary between two materials.

FIND: Finite-difference equation for steady-state conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) No internal heat generation, (5) Negligible thermal contact resistance at interface.

ANALYSIS: The control volume is defined about nodal point 0 as shown above. The conservation of energy requirement has the form

$$\sum_{i=1}^6 q_i = q_1 + q_2 + q_3 + q_4 + q_5 + q_6 = 0$$

since all heat rates are shown as *into* the CV. Each heat rate can be written using Fourier's law,

$$k_A \cdot \frac{\Delta y}{2} \cdot \frac{T_1 - T_0}{\Delta x} + k_A \cdot \Delta x \cdot \frac{T_2 - T_0}{\Delta y} + k_A \cdot \frac{\Delta y}{2} \cdot \frac{T_3 - T_0}{\Delta x} + k_B \cdot \frac{\Delta y}{2} \cdot \frac{T_3 - T_0}{\Delta x} + k_B \cdot \Delta x \cdot \frac{T_4 - T_0}{\Delta y} + k_B \cdot \frac{\Delta y}{2} \cdot \frac{T_1 - T_0}{\Delta x} = 0.$$

Recognizing that $\Delta x = \Delta y$ and regrouping gives the relation,

$$-T_0 + \frac{1}{4}T_1 + \frac{k_A}{2(k_A + k_B)}T_2 + \frac{1}{4}T_3 + \frac{k_B}{2(k_A + k_B)}T_4 = 0.$$

<

COMMENTS: Note that when $k_A = k_B$, the result agrees with Equation 4.29 which is appropriate for an interior node in a medium of fixed thermal conductivity.

PROBLEM 4.41

KNOWN: Two-dimensional grid for a system with no internal volumetric generation.

FIND: Expression for heat rate per unit length normal to page crossing the isothermal boundary.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional heat transfer, (3) Constant properties.

ANALYSIS: Identify the surface nodes (T_s) and draw control volumes about these nodes. Since there is no heat transfer in the direction parallel to the isothermal surfaces, the heat rate out of the constant temperature surface boundary is

$$q' = q'_a + q'_b + q'_c + q'_d + q'_e + q'_f$$

For each q'_i , use Fourier's law and pay particular attention to the manner in which the cross-sectional area and gradients are specified.

$$q' = k(\Delta y/2) \frac{T_1 - T_s}{\Delta x} + k(\Delta y) \frac{T_2 - T_s}{\Delta x} + k(\Delta y) \frac{T_3 - T_s}{\Delta x} + k(\Delta x) \frac{T_5 - T_s}{\Delta y} + k(\Delta x) \frac{T_6 - T_s}{\Delta y} + k(\Delta x/2) \frac{T_7 - T_s}{\Delta y}$$

Regrouping with $\Delta x = \Delta y$, find

$$q' = k[0.5T_1 + T_2 + T_3 + T_5 + T_6 + 0.5T_7 - 5T_s].$$

<

COMMENTS: Looking at the corner node, it is important to recognize the areas associated with q'_c and q'_d (Δy and Δx , respectively).

PROBLEM 4.42

KNOWN: One-dimensional fin of uniform cross section insulated at one end with prescribed base temperature, convection process on surface, and thermal conductivity.

FIND: Finite-difference equation for these nodes: (a) Interior node, m and (b) Node at end of fin, n , where $x = L$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction.

ANALYSIS: (a) The control volume about node m is shown in the schematic; the node spacing and control volume length in the x direction are both Δx . The uniform cross-sectional area and fin perimeter are A_c and P , respectively. The heat transfer process on the control surfaces, q_1 and q_2 , represent conduction while q_c is the convection heat transfer rate between the fin and ambient fluid. Performing an energy balance, find

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_1 + q_2 + q_c = 0$$

$$kA_c \frac{T_{m-1} - T_m}{\Delta x} + kA_c \frac{T_{m+1} - T_m}{\Delta x} + hP\Delta x (T_\infty - T_m) = 0.$$

Multiply the expression by $\Delta x/kA_c$ and regroup to obtain

$$T_{m-1} + T_{m+1} + \frac{hP}{kA_c} \cdot \Delta x^2 T_\infty - \left[2 + \frac{hP}{kA_c} \Delta x^2 \right] T_m = 0 \quad 1 < m < n \quad <$$

Considering now the special node $m = 1$, then the $m-1$ node is T_b , the base temperature. The finite-difference equation would be

$$T_b + T_2 + \frac{hP}{kA_c} \Delta x^2 T_\infty - \left[2 + \frac{hP}{kA_c} \Delta x^2 \right] T_1 = 0 \quad m=1 \quad <$$

(b) The control volume of length $\Delta x/2$ about node n is shown in the schematic. Performing an energy balance,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_3 + q_4 + q_c = 0$$

$$kA_c \frac{T_{n-1} - T_n}{\Delta x} + 0 + hP \frac{\Delta x}{2} (T_\infty - T_n) = 0.$$

Note that $q_4 = 0$ since the end ($x = L$) is insulated. Multiplying by $\Delta x/kA_c$ and regrouping,

$$T_{n-1} + \frac{hP}{kA_c} \cdot \frac{\Delta x^2}{2} T_\infty - \left[\frac{hP}{kA_c} \cdot \frac{\Delta x^2}{2} + 1 \right] T_n = 0. \quad <$$

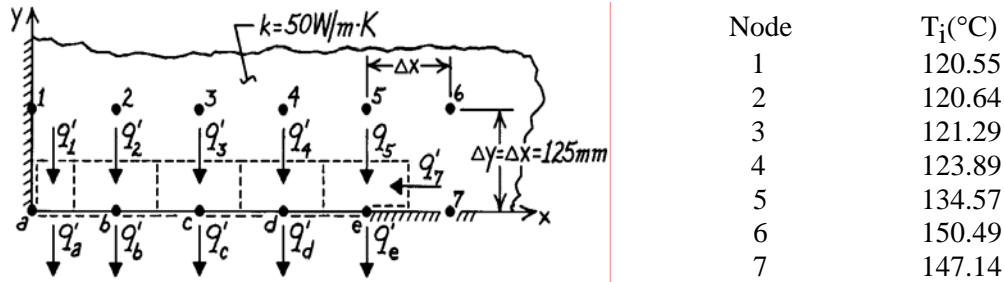

COMMENTS: The value of Δx will be determined by the selection of n ; that is, $\Delta x = L/n$. Note that the grouping, hP/kA_c , appears in the finite-difference and differential forms of the energy balance.

PROBLEM 4.43

KNOWN: Two-dimensional network with prescribed nodal temperatures and thermal conductivity of the material.

FIND: Heat rate per unit length normal to page, q' .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional heat transfer, (3) No internal volumetric generation, (4) Constant properties.

ANALYSIS: Construct control volumes around the nodes on the surface maintained at the uniform temperature T_s and indicate the heat rates. The heat rate per unit length is $q' = q'_a + q'_b + q'_c + q'_d + q'_e$ or in terms of conduction terms between nodes,

$$q' = q'_1 + q'_2 + q'_3 + q'_4 + q'_5 + q'_7.$$

Each of these rates can be written in terms of nodal temperatures and control volume dimensions using Fourier's law,

$$q' = k \cdot \frac{\Delta x}{2} \cdot \frac{T_1 - T_s}{\Delta y} + k \cdot \Delta x \cdot \frac{T_2 - T_s}{\Delta y} + k \cdot \Delta x \cdot \frac{T_3 - T_s}{\Delta y} + k \cdot \Delta x \cdot \frac{T_4 - T_s}{\Delta y} + k \cdot \Delta x \cdot \frac{T_5 - T_s}{\Delta y} + k \cdot \frac{\Delta y}{2} \cdot \frac{T_7 - T_s}{\Delta x}.$$

and since $\Delta x = \Delta y$,

$$q' = k[(1/2)(T_1 - T_s) + (T_2 - T_s) + (T_3 - T_s) + (T_4 - T_s) + (T_5 - T_s) + (1/2)(T_7 - T_s)].$$

Substituting numerical values, find

$$q' = 50 \text{ W/m} \cdot \text{K}[(1/2)(120.55 - 100) + (120.64 - 100) + (121.29 - 100) + (123.89 - 100) + (134.57 - 100) + (1/2)(147.14 - 100)]$$

$$q' = 6711 \text{ W/m.}$$

<

COMMENTS: For nodes a through d, there is no heat transfer into the control volumes in the x -direction. Look carefully at the energy balance for node e, $q'_e = q'_5 + q'_7$, and how q'_5 and q'_7 are evaluated.

PROBLEM 4.44

KNOWN: Nodal temperatures from a steady-state, finite-difference analysis for a one-eighth symmetrical section of a square channel.

FIND: (a) Beginning with properly defined control volumes, derive the finite-difference equations for nodes 2, 4 and 7, and determine T_2 , T_4 and T_7 , and (b) Heat transfer loss per unit length from the channel, q' .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) No internal volumetric generation, (4) Constant properties.

ANALYSIS: (a) Define control volumes about the nodes 2, 4, and 7, taking advantage of symmetry where appropriate and performing energy balances, $\dot{E}_{in} - \dot{E}_{out} = 0$, with $\Delta x = \Delta y$,

Node 2: $q'_a + q'_b + q'_c + q'_d = 0$

$$h\Delta x(T_\infty - T_2) + k(\Delta y/2) \frac{T_3 - T_2}{\Delta x} + k\Delta x \frac{T_6 - T_2}{\Delta y} + k(\Delta y/2) \frac{T_1 - T_2}{\Delta x} = 0$$

$$T_2 = \left[0.5T_1 + 0.5T_3 + T_6 + (h\Delta x/k)T_\infty \right] / \left[2 + (h\Delta x/k) \right]$$

$$T_2 = \left[0.5 \times 430 + 0.5 \times 394 + 492 + \left(50 \text{ W/m}^2 \cdot \text{K} \times 0.01 \text{ m} / 1 \text{ W/m} \cdot \text{K} \right) 300 \right] \text{ K} / [2 + 0.50]$$

$$T_2 = 422 \text{ K}$$

<

Node 4: $q'_a + q'_b + q'_c = 0$

$$h(\Delta x/2)(T_\infty - T_4) + 0 + k(\Delta y/2) \frac{T_3 - T_4}{\Delta x} = 0$$

$$T_4 = \left[T_3 + (h\Delta x/k)T_\infty \right] / \left[1 + (h\Delta x/k) \right]$$

$$T_4 = \left[394 + 0.5 \times 300 \right] \text{ K} / [1 + 0.5] = 363 \text{ K}$$

<

Continued...

PROBLEM 4.44 (Cont.)

Node 7: From the first schematic, recognizing that the diagonal is a symmetry adiabat, we can treat node 7 as an interior node, hence

$$T_7 = 0.25(T_3 + T_3 + T_6 + T_6) = 0.25(394 + 394 + 492 + 492) \text{ K} = 443 \text{ K} \quad <$$

(b) The heat transfer loss from the upper surface can be expressed as the sum of the convection rates from each node as illustrated in the first schematic,

$$q'_{cv} = q'_1 + q'_2 + q'_3 + q'_4$$

$$q'_{cv} = h(\Delta x/2)(T_1 - T_\infty) + h\Delta x(T_2 - T_\infty) + h\Delta x(T_3 - T_\infty) + h(\Delta x/2)(T_4 - T_\infty)$$

$$q'_{cv} = 50 \text{ W/m}^2 \cdot \text{K} \times 0.01 \text{ m} \left[(430 - 300)/2 + (422 - 300) + (394 - 300) + (363 - 300)/2 \right] \text{ K}$$

$$q'_{cv} = 156 \text{ W/m} \quad <$$

COMMENTS: (1) Always look for symmetry conditions which can greatly simplify the writing of the nodal equation as was the case for Node 7.

(2) Consider using the *IHT Tool, Finite-Difference Equations*, for *Steady-State, Two-Dimensional* heat transfer to determine the nodal temperatures $T_1 - T_7$ when only the boundary conditions T_8 , T_9 and (T_∞, h) are specified.

PROBLEM 4.45

KNOWN: Steady-state temperatures (K) at three nodes of a long rectangular bar.

FIND: (a) Temperatures at remaining nodes and (b) heat transfer per unit length from the bar using nodal temperatures; compare with result calculated using knowledge of \dot{q} .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, 2-D conduction, (2) Constant properties.

ANALYSIS: (a) The finite-difference equations for the nodes (1,2,3,A,B,C) can be written by inspection using Eq. 4.35 and recognizing that the adiabatic boundary can be represented by a symmetry plane.

$$\sum T_{\text{neighbors}} - 4T_i + \dot{q}\Delta x^2/k = 0 \quad \text{and} \quad \frac{\dot{q}\Delta x^2}{k} = \frac{5 \times 10^7 \text{ W/m}^3 (0.005 \text{ m})^2}{20 \text{ W/m} \cdot \text{K}} = 62.5 \text{ K}.$$

Node A (to find T_2):

$$2T_2 + 2T_B - 4T_A + \dot{q}\Delta x^2/k = 0$$

$$T_2 = \frac{1}{2}(-2 \times 374.6 + 4 \times 398.0 - 62.5) \text{ K} = 390.2 \text{ K} \quad <$$

Node 3 (to find T_3):

$$T_C + T_2 + T_B + 300 \text{ K} - 4T_3 + \dot{q}\Delta x^2/k = 0$$

$$T_3 = \frac{1}{4}(348.5 + 390.2 + 374.6 + 300 + 62.5) \text{ K} = 369.0 \text{ K} \quad <$$

Node 1 (to find T_1):

$$300 + 2T_C + T_2 - 4T_1 + \dot{q}\Delta x^2/k = 0$$

$$T_1 = \frac{1}{4}(300 + 2 \times 348.5 + 390.2 + 62.5) = 362.4 \text{ K} \quad <$$

(b) The heat rate out of the bar is determined by calculating the heat rate out of each control volume around the 300 K nodes. Consider the node in the upper left-hand corner; from an energy balance

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0 \quad \text{or} \quad q'_a = q'_{a,\text{in}} + \dot{E}_g \quad \text{where} \quad \dot{E}_g = \dot{q}V.$$

Hence, for the entire bar

$$q'_{\text{bar}} = q'_a + q'_b + q'_c + q'_d + q'_e + q'_f, \quad \text{or}$$

$$q'_{\text{bar}} = \left[k \frac{\Delta y}{2} \frac{T_1 - 300}{\Delta x} + \dot{q} \left[\frac{\Delta x}{2} \cdot \frac{\Delta y}{2} \right] \right]_a + \left[k \Delta y \frac{T_C - 300}{\Delta x} + \dot{q} \left[\frac{\Delta x}{2} \cdot \Delta y \right] \right]_b + \left[\dot{q} \left[\frac{\Delta x}{2} \cdot \frac{\Delta y}{2} \right] \right]_c + \left[k \Delta x \frac{T_C - 300}{\Delta y} + \dot{q} \left[\Delta x \cdot \frac{\Delta y}{2} \right] \right]_d + \left[k \Delta x \frac{T_3 - 300}{\Delta y} + \dot{q} \left[\Delta x \cdot \frac{\Delta y}{2} \right] \right]_e + \left[k \frac{\Delta x}{2} \frac{T_B - 300}{\Delta y} + \dot{q} \left[\frac{\Delta x}{2} \cdot \frac{\Delta y}{2} \right] \right]_f.$$

Substituting numerical values, find $q'_{\text{bar}} = 7,502.5 \text{ W/m}$. From an overall energy balance on the bar,

$$q'_{\text{bar}} = \dot{E}'_g = \dot{q}V/\ell = \dot{q}(3\Delta x \cdot 2\Delta y) = 5 \times 10^7 \text{ W/m}^3 \times 6(0.005 \text{ m})^2 = 7,500 \text{ W/m}. \quad <$$

As expected, the results of the two methods agree. Why must that be?

PROBLEM 4.46

KNOWN: Steady-state temperatures at selected nodal points of the symmetrical section of a flow channel with uniform internal volumetric generation of heat. Inner and outer surfaces of channel experience convection.

FIND: (a) Temperatures at nodes 1, 4, 7, and 9, (b) Heat rate per unit length (W/m) from the outer surface A to the adjacent fluid, (c) Heat rate per unit length (W/m) from the inner fluid to surface B, and (d) Verify that results are consistent with an overall energy balance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) The nodal finite-difference equations are obtained from energy balances on control volumes about the nodes shown in the schematics below.

Node 1

$$q'_a + q'_b + q'_c + q'_d + \dot{E}'_g = 0$$

$$0 + k(\Delta y/2) \frac{T_2 - T_1}{\Delta x} + k(\Delta x/2) \frac{T_3 - T_1}{\Delta y} + 0 + \dot{q}(\Delta x \cdot \Delta y/4) = 0$$

$$T_1 = (T_2 + T_3)/2 + \dot{q}\Delta x^2/4k$$

$$T_1 = (95.47 + 117.3)^\circ\text{C}/2 + 10^6 \text{ W/m}^3 (25 \times 25) \times 10^{-6} \text{ m}^2 / (4 \times 10 \text{ W/m} \cdot \text{K}) = 122.0^\circ\text{C}$$

Node 4

Node 4

$$q'_a + q'_b + q'_c + q'_d + q'_e + q'_f + \dot{E}'_g = 0$$

$$k(\Delta x/2) \frac{T_2 - T_4}{\Delta y} + h_i(\Delta y/2)(T_{\infty,i} - T_4) + h_i(\Delta x/2)(T_{\infty,i} - T_4) +$$

PROBLEM 4.46 (Cont.)

$$k(\Delta y/2) \frac{T_5 - T_4}{\Delta x} + k(\Delta x) \frac{T_8 - T_4}{\Delta y} + k(\Delta y) \frac{T_3 - T_4}{\Delta x} + \dot{q}(3\Delta x \cdot \Delta y/4) = 0$$

$$T_4 = \left[T_2 + 2T_3 + T_5 + 2T_8 + 2(h_i \Delta x/k) T_{\infty,i} + (3\dot{q}\Delta x^2/2k) \right] / [6 + 2(h_i \Delta x/k)]$$

$$T_4 = 94.50^\circ\text{C}$$

<

Node 7

$$q'_a + q'_b + q'_c + q'_d + \dot{E}'_g = 0$$

$$k(\Delta x/2) \frac{T_3 - T_7}{\Delta y} + k(\Delta y/2) \frac{T_8 - T_7}{\Delta x} + h_o(\Delta x/2)(T_{\infty,o} - T_7) + 0 + \dot{q}(\Delta x \cdot \Delta y/4) = 0$$

$$T_7 = \left[T_3 + T_8 + (h_o \Delta x/k) T_{\infty,o} + \dot{q}\Delta x^2/2k \right] / (2 + h_o \Delta x/k)$$

$$T_7 = 95.80^\circ\text{C}$$

<

Node 9

$$q'_a + q'_b + q'_c + q'_d + \dot{E}'_g = 0$$

$$k(\Delta x) \frac{T_5 - T_9}{\Delta y} + k(\Delta y/2) \frac{T_{10} - T_9}{\Delta y} + h_o(\Delta x)(T_{\infty,o} - T_9) + k(\Delta y/2) \frac{T_8 - T_9}{\Delta x} + \dot{q}(\Delta x \cdot \Delta y/2) = 0$$

$$T_9 = \left[T_5 + 0.5T_8 + 0.5T_{10} + (h_o \Delta x/k) T_{\infty,o} + \dot{q}\Delta x^2/2k \right] / (2 + h_o \Delta x/k)$$

$$T_9 = 79.67^\circ\text{C}$$

<

(b) The heat rate per unit length from the outer surface A to the adjacent fluid, q'_A , is the sum of the convection heat rates from the outer surfaces of nodes 7, 8, 9 and 10.

$$q'_A = h_o \left[(\Delta x/2)(T_7 - T_{\infty,o}) + \Delta x(T_8 - T_{\infty,o}) + \Delta x(T_9 - T_{\infty,o}) + (\Delta x/2)(T_{10} - T_{\infty,o}) \right]$$

$$q'_A = 250 \text{ W/m}^2 \cdot \text{K} \left[(25/2)(95.80 - 25) + 25(87.28 - 25) + 25(79.67 - 25) + (25/2)(77.65 - 25) \right] \times 10^{-3} \text{ m} \cdot \text{K}$$

Continued

PROBLEM 4.46 (Cont.)

$$q'_A = 1117 \text{ W/m}$$

<

(c) The heat rate per unit length from the inner fluid to the surface B, q'_B , is the sum of the convection heat rates from the inner surfaces of nodes 2, 4, 5 and 6.

$$q'_B = h_i \left[(\Delta y / 2)(T_{\infty,i} - T_2) + (\Delta y / 2 + \Delta x / 2)(T_{\infty,i} - T_4) + \Delta x(T_{\infty,i} - T_5) + (\Delta x / 2)(T_{\infty,i} - T_6) \right]$$

$$q'_B = 500 \text{ W/m}^2 \cdot \text{K} \left[(25/2)(50 - 95.47) + (25/2 + 25/2)(50 - 94.50) \right. \\ \left. + 25(50 - 79.79) + (25/2)(50 - 77.29) \right] \times 10^{-3} \text{ m} \cdot \text{K}$$

$$q'_B = -1383 \text{ W/m}$$

<

(d) From an overall energy balance on the section, we see that our results are consistent since the conservation of energy requirement is satisfied.

$$\dot{E}'_{\text{in}} - \dot{E}'_{\text{out}} + \dot{E}'_{\text{gen}} = -q'_A + q'_B + \dot{E}'_{\text{gen}} = (-1117 - 1383 + 2500) \text{ W/m} = 0$$

where $\dot{E}'_{\text{gen}} = \dot{q} \forall' = 10^6 \text{ W/m}^3 [25 \times 50 + 25 \times 50] \times 10^{-6} \text{ m}^2 = 2500 \text{ W/m}$

COMMENTS: The nodal finite-difference equations for the four nodes can be obtained by using IHT Tool *Finite-Difference Equations | Two-Dimensional | Steady-state*. Options are provided to build the FDEs for interior, corner and surface nodal arrangements including convection and internal generation. The IHT code lines for the FDEs are shown below.

```
/* Node 1: interior node; e, w, n, s labeled 2, 2, 3, 3. */
0.0 = fd_2d_int(T1,T2,T2,T3,T3,k,qdot,deltax,deltay)

/* Node 4: internal corner node, e-n orientation; e, w, n, s labeled 5, 3, 2, 8. */
0.0 = fd_2d_ic_en(T4,T5,T3,T2,T8,k,qdot,deltax,deltay,Tinfo,hi,q"a4
q"a4 = 0 // Applied heat flux, W/m^2; zero flux shown

/* Node 7: plane surface node, s-orientation; e, w, n labeled 8, 8, 3. */
0.0 = fd_2d_psur_s(T7,T8,T8,T3,k,qdot,deltax,deltay,Tinfo,ho,q"a7
q"a7=0 // Applied heat flux, W/m^2; zero flux shown

/* Node 9: plane surface node, s-orientation; e, w, n labeled 10, 8, 5. */
0.0 = fd_2d_psur_s(T9, T10, T8, T5,k,qdot,deltax,deltay,Tinfo,ho,q"a9
q"a9 = 0 // Applied heat flux, W/m^2; zero flux shown
```

PROBLEM 4.47

KNOWN: Outer surface temperature, inner convection conditions, dimensions and thermal conductivity of a heat sink.

FIND: Nodal temperatures and heat rate per unit length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Two-dimensional conduction, (3) Uniform outer surface temperature, (4) Constant thermal conductivity.

ANALYSIS: (a) To determine the heat rate, the nodal temperatures must first be computed from the corresponding finite-difference equations. From an energy balance for node 1,

$$h(\Delta x / 2 \cdot 1)(T_{\infty} - T_1) + k(\Delta y / 2 \cdot 1) \frac{T_2 - T_1}{\Delta x} + k(\Delta x \cdot 1) \frac{T_5 - T_1}{\Delta y} = 0$$

$$-\left(3 + \frac{h\Delta x}{k}\right)T_1 + T_2 + 2T_5 + \frac{h\Delta x}{k}T_{\infty} = 0 \quad (1)$$

With nodes 2 and 3 corresponding to Case 3 of Table 4.2,

$$T_1 - 2\left(\frac{h\Delta x}{k} + 2\right)T_2 + T_3 + 2T_6 + \frac{2h\Delta x}{k}T_{\infty} = 0 \quad (2)$$

$$T_2 - \left(\frac{h\Delta x}{k} + 2\right)T_3 + T_7 + \frac{h\Delta x}{k}T_{\infty} = 0 \quad (3)$$

where the symmetry condition is invoked for node 3. Applying an energy balance to node 4, we obtain

$$-2T_4 + T_5 + T_s = 0 \quad (4)$$

The interior nodes 5, 6 and 7 correspond to Case 1 of Table 4.2. Hence,

$$T_1 + T_4 - 4T_5 + T_6 + T_s = 0 \quad (5)$$

$$T_2 + T_5 - 4T_6 + T_7 + T_s = 0 \quad (6)$$

$$T_3 + 2T_6 - 4T_7 + T_s = 0 \quad (7)$$

where the symmetry condition is invoked for node 7. With $T_s = 50^\circ\text{C}$, $T_{\infty} = 20^\circ\text{C}$, and

$h\Delta x / k = 5000 \text{ W/m}^2 \cdot \text{K} (0.005\text{m}) / 240 \text{ W/m} \cdot \text{K} = 0.1042$, the solution to Eqs. (1) – (7) yields

$$T_1 = 46.61^\circ\text{C}, T_2 = 45.67^\circ\text{C}, T_3 = 45.44^\circ\text{C}, T_4 = 49.23^\circ\text{C}$$

$$T_5 = 48.46^\circ\text{C}, T_6 = 48.00^\circ\text{C}, T_7 = 47.86^\circ\text{C}$$

<

Continued

PROBLEM 4.47 (Cont.)

The heat rate per unit length of channel may be evaluated by computing convection heat transfer from the inner surface. That is,

$$q' = 8h \left[\Delta x / 2 (T_1 - T_\infty) + \Delta x (T_2 - T_\infty) + \Delta x / 2 (T_3 - T_\infty) \right]$$

$$q' = 8 \times 5000 \text{ W/m}^2 \cdot \text{K} \left[0.0025 \text{ m} (46.61 - 20)^\circ\text{C} + 0.005 \text{ m} (45.67 - 20)^\circ\text{C} \right.$$

$$\left. + 0.0025 \text{ m} (45.44 - 20)^\circ\text{C} \right] = 10,340 \text{ W/m} \quad <$$

(b) Since $h = 5000 \text{ W/m}^2 \cdot \text{K}$ is at the high end of what can be achieved through forced convection, we consider the effect of reducing h . Representative results are as follows

$h \left(\text{W/m}^2 \cdot \text{K} \right)$	$T_1 (^\circ\text{C})$	$T_2 (^\circ\text{C})$	$T_3 (^\circ\text{C})$	$T_4 (^\circ\text{C})$	$T_5 (^\circ\text{C})$	$T_6 (^\circ\text{C})$	$T_7 (^\circ\text{C})$	$q' (\text{W/m})$
200	49.84	49.80	49.79	49.96	49.93	49.91	49.90	477
1000	49.24	49.02	48.97	49.83	49.65	49.55	49.52	2325
2000	48.53	48.11	48.00	49.66	49.33	49.13	49.06	4510
5000	46.61	45.67	45.44	49.23	48.46	48.00	47.86	10,340

There are two resistances to heat transfer between the outer surface of the heat sink and the fluid, that due to conduction in the heat sink, $R_{\text{cond}}(2D)$, and that due to convection from its inner surface to the fluid, R_{conv} . With decreasing h , the corresponding increase in R_{conv} reduces heat flow and increases the uniformity of the temperature field in the heat sink. The nearly 5-fold reduction in q'

corresponding to the 5-fold reduction in h from 1000 to $200 \text{ W/m}^2 \cdot \text{K}$ indicates that the convection resistance is dominant ($R_{\text{conv}} \gg R_{\text{cond}}(2D)$).

COMMENTS: To check our finite-difference solution, we could assess its consistency with conservation of energy requirements. For example, an energy balance performed at the inner surface requires a balance between convection from the surface and conduction to the surface, which may be expressed as

$$q' = k(\Delta x \cdot 1) \frac{(T_5 - T_1)}{\Delta y} + k(\Delta x \cdot 1) \frac{T_6 - T_2}{\Delta y} + k(\Delta x / 2 \cdot 1) \frac{T_7 - T_3}{\Delta y}$$

Substituting the temperatures corresponding to $h = 5000 \text{ W/m}^2 \cdot \text{K}$, the expression yields

$q' = 10,340 \text{ W/m}$, and, as it must be, conservation of energy is precisely satisfied. Results of the analysis may also be checked by using the expression $q' = (T_s - T_\infty) / (R'_{\text{cond}}(2D) + R'_{\text{conv}})$, where, for

$h = 5000 \text{ W/m}^2 \cdot \text{K}$, $R'_{\text{conv}} = (1/4hw) = 2.5 \times 10^{-3} \text{ m} \cdot \text{K/W}$, and from Eq. (4.27) and Case 11 of

Table 4.1, $R'_{\text{cond}} = [0.930 \ln(W/w) - 0.05] / 2\pi k = 3.94 \times 10^{-4} \text{ m} \cdot \text{K/W}$. Hence,

$q' = (50 - 20)^\circ\text{C} / (2.5 \times 10^{-3} + 3.94 \times 10^{-4}) \text{ m} \cdot \text{K/W} = 10,370 \text{ W/m}$, and the agreement with the

finite-difference solution is excellent. Note that, even for $h = 5000 \text{ W/m}^2 \cdot \text{K}$, $R'_{\text{conv}} \gg R'_{\text{cond}}(2D)$.

PROBLEM 4.48

KNOWN: Steady-state temperatures ($^{\circ}\text{C}$) associated with selected nodal points in a two-dimensional system.

FIND: (a) Temperatures at nodes 1, 2 and 3, (b) Heat transfer rate per unit thickness from the system surface to the fluid.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Using the finite-difference equations for Nodes 1, 2 and 3:

Node 1, Interior node, Eq. 4.29: $T_1 = \frac{1}{4} \cdot \sum T_{\text{neighbors}}$

$$T_1 = \frac{1}{4} (172.9 + 137.0 + 132.8 + 200.0)^{\circ}\text{C} = 160.7^{\circ}\text{C}$$

Node 2, Insulated boundary, Eq. 4.46 with $h = 0$, $T_{m,n} = T_2$

$$T_2 = \frac{1}{4} (T_{m-1,n} + T_{m+1,n} + 2T_{m,n-1})$$

$$T_2 = \frac{1}{4} (129.4 + 45.8 + 2 \times 103.5)^{\circ}\text{C} = 95.6^{\circ}\text{C}$$

Node 3, Plane surface with convection, Eq. 4.42, $T_{m,n} = T_3$

$$2 \left[\frac{h\Delta x}{k} + 2 \right] T_3 = (2T_{m-1,n} + T_{m,n+1} + T_{m,n-1}) + \frac{2h\Delta x}{k} T_{\infty}$$

$$h\Delta x/k = 50 \text{ W/m}^2 \cdot \text{K} \times 0.1 \text{ m} / 1.5 \text{ W/m} \cdot \text{K} = 3.33$$

$$2(3.33 + 2)T_3 = (2 \times 103.5 + 45.8 + 67.0)^{\circ}\text{C} + 2 \times 3.33 \times 30^{\circ}\text{C}$$

$$T_3 = \frac{1}{10.66} (319.80 + 199.80)^{\circ}\text{C} = 48.7^{\circ}\text{C}$$

(b) The heat rate per unit thickness from the surface to the fluid is determined from the sum of the convection rates from each control volume surface.

$$q'_{\text{conv}} = q'_a + q'_b + q'_c + q'_d$$

$$q_i = h\Delta y_i (T_i - T_{\infty})$$

$$q'_{\text{conv}} = 50 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \left[\frac{0.1}{2} \text{ m} (45.8 - 30.0)^{\circ}\text{C} + 0.1 \text{ m} (48.7 - 30.0)^{\circ}\text{C} + 0.1 \text{ m} (67.0 - 30.0)^{\circ}\text{C} + \frac{0.1}{2} (200.0 - 30.0)^{\circ}\text{C} \right]$$

$$q'_{\text{conv}} = (39.5 + 93.5 + 185.0 + 425) \text{ W/m} = 743 \text{ W/m.}$$

PROBLEM 4.49

KNOWN: Nodal temperatures from a steady-state finite-difference analysis for a cylindrical fin of prescribed diameter, thermal conductivity and convection conditions (T_∞ , h).

FIND: (a) The fin heat rate, q_f , and (b) Temperature at node 3, T_3 .

SCHEMATIC:

ASSUMPTIONS: (a) The fin heat rate, q_f , is that of conduction at the base plane, $x = 0$, and can be found from an energy balance on the control volume about node 0, $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$,

$$q_f + q_1 + q_{\text{conv}} = 0 \quad \text{or} \quad q_f = -q_1 - q_{\text{conv}}.$$

Writing the appropriate rate equation for q_1 and q_{conv} , with $A_c = \pi D^2/4$ and $P = \pi D$,

$$q_f = -kA_c \frac{T_1 - T_0}{\Delta x} - hP(\Delta x/2)(T_\infty - T_0) = -\frac{\pi k D^2}{4 \Delta x} (T_1 - T_0) - (\pi/2) D h \Delta x (T_\infty - T_0)$$

Substituting numerical values, with $\Delta x = 0.010 \text{ m}$, find

$$q_f = -\frac{\pi \times 15 \text{ W/m}\cdot\text{K} (0.012 \text{ m})^2}{4 \times 0.010 \text{ m}} (93.4 - 100)^\circ\text{C} - \frac{\pi}{2} \times 0.012 \text{ m} \times 25 \text{ W/m}^2\cdot\text{K} \times 0.010 \text{ m} (25 - 100)^\circ\text{C}$$

$$q_f = (1.120 + 0.353) \text{ W} = 1.473 \text{ W}.$$

(b) To determine T_3 , derive the finite-difference equation for node 3, perform an energy balance on the control volume shown above, $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$,

$$q_{\text{cv}} + q_3 + q_1 = 0$$

$$hP\Delta x (T_\infty - T_2) + kA_c \frac{T_3 - T_2}{\Delta x} + kA_c \frac{T_1 - T_2}{\Delta x} = 0$$

$$T_3 = -T_1 + 2T_2 - \frac{hP\Delta x^2}{kA_c} [T_\infty - T_2]$$

Substituting numerical values, find

$$T_3 = 89.2^\circ\text{C}$$

COMMENTS: Note that in part (a), the convection heat rate from the outer surface of the control volume is significant (25%). It would have been a poor approximation to ignore this term.

PROBLEM 4.50

KNOWN: Long rectangular bar having one boundary exposed to a convection process (T_∞, h) while the other boundaries are maintained at a constant temperature (T_s).

FIND: (a) Using a grid spacing of 30 mm and the Gauss-Seidel method, determine the nodal temperatures and the heat rate per unit length into the bar from the fluid, (b) Effect of grid spacing and convection coefficient on the temperature field.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) With the grid spacing $\Delta x = \Delta y = 30$ mm, three nodes are created. Using the finite-difference equations as shown in Table 4.2, but written in the form required of the Gauss-Seidel method (see Section 4.5.2), and with $Bi = h\Delta x/k = 100 \text{ W/m}^2\cdot\text{K} \times 0.030 \text{ m}/1 \text{ W/m}\cdot\text{K} = 3$, we obtain:

$$\text{Node 1: } T_1 = \frac{1}{(Bi + 2)}(T_2 + T_s + BiT_\infty) = \frac{1}{5}(T_2 + 50 + 3 \times 100) = \frac{1}{5}(T_2 + 350) \quad (1)$$

$$\text{Node 2: } T_2 = \frac{1}{4}(T_1 + 2T_s + T_3) = \frac{1}{4}(T_1 + T_3 + 2 \times 50) = \frac{1}{4}(T_1 + T_3 + 100) \quad (2)$$

$$\text{Node 3: } T_3 = \frac{1}{4}(T_2 + 3T_s) = \frac{1}{4}(T_2 + 3 \times 50) = \frac{1}{4}(T_2 + 150) \quad (3)$$

Denoting each nodal temperature with a superscript to indicate iteration step, e.g. T_1^k , calculate values as shown below.

k	T_1	T_2	T_3 (°C)	
0	85	60	55	← initial guess
1	82.00	59.25	52.31	
2	81.85	58.54	52.14	
3	81.71	58.46	52.12	
4	81.69	58.45	52.11	

By the 4th iteration, changes are of order 0.02°C , suggesting that further calculations may not be necessary.

Continued...

PROBLEM 4.50 (Cont.)

In finite-difference form, the heat rate from the fluid to the bar is

$$q'_{\text{conv}} = h(\Delta x/2)(T_{\infty} - T_s) + h\Delta x(T_{\infty} - T_1) + h(\Delta x/2)(T_{\infty} - T_s)$$

$$q'_{\text{conv}} = h\Delta x(T_{\infty} - T_s) + h\Delta x(T_{\infty} - T_1) = h\Delta x[(T_{\infty} - T_s) + (T_{\infty} - T_1)]$$

$$q'_{\text{conv}} = 100 \text{ W/m}^2 \cdot \text{K} \times 0.030 \text{ m} [(100 - 50) + (100 - 81.7)]^{\circ}\text{C} = 205 \text{ W/m} . \quad <$$

(b) Using the *Finite-Difference Equations* option from the *Tools* portion of the IHT menu, the following two-dimensional temperature field was computed for the grid shown in schematic (b), where x and y are in mm and the temperatures are in $^{\circ}\text{C}$.

$y \backslash x$	0	15	30	45	60
0	50	80.33	85.16	80.33	50
15	50	63.58	67.73	63.58	50
30	50	56.27	58.58	56.27	50
45	50	52.91	54.07	52.91	50
60	50	51.32	51.86	51.32	50
75	50	50.51	50.72	50.51	50
90	50	50	50	50	50

The improved prediction of the temperature field has a significant influence on the heat rate, where, accounting for the symmetrical conditions,

$$q' = 2h(\Delta x/2)(T_{\infty} - T_s) + 2h(\Delta x)(T_{\infty} - T_1) + h(\Delta x)(T_{\infty} - T_2)$$

$$q' = h(\Delta x)[(T_{\infty} - T_s) + 2(T_{\infty} - T_1) + (T_{\infty} - T_2)]$$

$$q' = 100 \text{ W/m}^2 \cdot \text{K} (0.015 \text{ m}) [50 + 2(19.67) + 14.84]^{\circ}\text{C} = 156.3 \text{ W/m} \quad <$$

Additional improvements in accuracy could be obtained by reducing the grid spacing to 5 mm, although the requisite number of finite-difference equations would increase from 12 to 108, significantly increasing problem *set-up* time.

An increase in h would increase temperatures everywhere within the bar, particularly at the heated surface, as well as the rate of heat transfer by convection to the surface.

COMMENTS: (1) Using the matrix-inversion method, the exact solution to the system of equations (1, 2, 3) of part (a) is $T_1 = 81.70^{\circ}\text{C}$, $T_2 = 58.44^{\circ}\text{C}$, and $T_3 = 52.12^{\circ}\text{C}$. The fact that only 4 iterations were required to obtain agreement within 0.01°C is due to the close initial guesses.

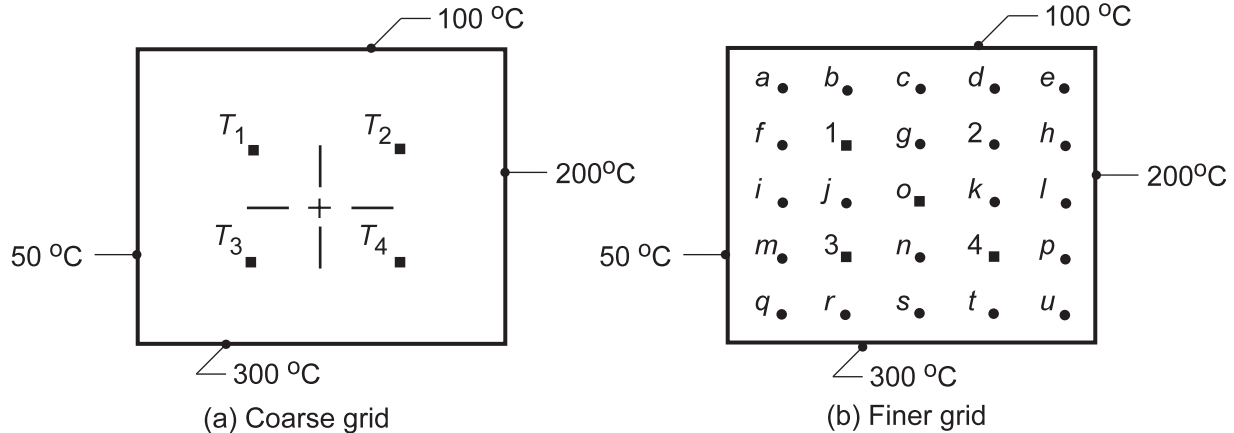

(2) Note that the rate of heat transfer by convection to the top surface of the rod must balance the rate of heat transfer by conduction to the sides and bottom of the rod.

PROBLEM 4.51

KNOWN: Square shape subjected to uniform surface temperature conditions.

FIND: (a) Temperature at the four specified nodes; estimate the midpoint temperature T_o , (b) Reducing the mesh size by a factor of 2, determine the corresponding nodal temperatures and compare results, and (c) For the finer grid, plot the 75, 150, and 250°C isotherms.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) The finite-difference equation for each node follows from Eq. 4.29 for an interior point written in the form, $T_i = 1/4 \sum T_{\text{neighbors}}$. Using the Gauss-Seidel iteration method, Section 4.5.2, the finite-difference equations for the four nodes are:

$$T_1^k = 0.25(100 + T_2^{k-1} + T_3^{k-1} + 50) = 0.25T_2^{k-1} + 0.25T_3^{k-1} + 37.5$$

$$T_2^k = 0.25(100 + 200 + T_4^{k-1} + T_1^{k-1}) = 0.25T_1^{k-1} + 0.25T_4^{k-1} + 75.0$$

$$T_3^k = 0.25(T_1^{k-1} + T_4^{k-1} + 300 + 50) = 0.25T_1^{k-1} + 0.25T_4^{k-1} + 87.5$$

$$T_4^k = 0.25(T_2^{k-1} + 200 + 300 + T_3^{k-1}) = 0.25T_2^{k-1} + 0.25T_3^{k-1} + 125.0$$

The iteration procedure using a hand calculator is implemented in the table below. Initial estimates are entered on the $k = 0$ row.

k	T_1 (°C)	T_2 (°C)	T_3 (°C)	T_4 (°C)
0	100	150	150	250
1	112.50	165.63	178.13	210.94
2	123.44	158.60	171.10	207.43
3	119.93	156.40	169.34	206.55
4	119.05	156.40	168.90	206.33
5	118.83	156.29	168.79	206.27
6	118.77	156.26	168.76	206.26
7	118.76	156.25	168.76	206.25

<

Continued...

PROBLEM 4.51 (Cont.)

By the seventh iteration, the convergence is approximately 0.01°C . The midpoint temperature can be estimated as

$$T_o = (T_1 + T_2 + T_3 + T_4)/4 = (118.76 + 156.25 + 168.76 + 206.25)^\circ\text{C}/4 = 162.5^\circ\text{C}$$

(b) Because all the nodes are interior ones, the nodal equations can be written by inspection directly into the IHT workspace and the set of equations solved for the nodal temperatures ($^\circ\text{C}$).

Mesh	T_o	T_1	T_2	T_3	T_4
Coarse	162.5	118.8	156.3	168.8	206.3
Fine	162.5	117.4	156.1	168.9	207.6

The maximum difference for the interior points is 1.4°C (node 1), but the estimate at the center, T_o , is the same, independently of the mesh size. In terms of the boundary surface temperatures,

$$T_o = (50 + 100 + 200 + 300)^\circ\text{C}/4 = 162.5^\circ\text{C}$$

Why must this be so?

(c) To generate the isotherms, it would be necessary to employ a contour-drawing routine using the tabulated temperature distribution ($^\circ\text{C}$) obtained from the finite-difference solution. Using these values as a guide, try sketching a few isotherms.

-	100	100	100	100	100	-
50	86.0	105.6	119	131.7	151.6	200
50	88.2	117.4	138.7	156.1	174.6	200
50	99.6	137.1	162.5	179.2	190.8	200
50	123.0	168.9	194.9	207.6	209.4	200
50	173.4	220.7	240.6	246.8	239.0	200
-	300	300	300	300	300	-

COMMENTS: Recognize that this finite-difference solution is only an approximation to the temperature distribution, since the heat conduction equation has been solved for only four (or 25) discrete points rather than for all points if an analytical solution had been obtained.

PROBLEM 4.52

KNOWN: Long bar of square cross section, three sides of which are maintained at a constant temperature while the fourth side is subjected to a convection process.

FIND: (a) The mid-point temperature and heat transfer rate between the bar and fluid; a numerical technique with grid spacing of 0.2 m is suggested, and (b) Reducing the grid spacing by a factor of 2, find the midpoint temperature and the heat transfer rate. Also, plot temperature distribution across the surface exposed to the fluid.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Considering symmetry, the nodal network is shown above. The matrix inversion method of solution will be employed. The finite-difference equations are:

- Nodes 1, 3, 5 - Interior nodes, Eq. 4.29; written by inspection.
- Nodes 2, 4, 6 - Also can be treated as interior points, considering symmetry.
- Nodes 7, 8 - On a plane with convection, Eq. 4.42; noting that $h\Delta x/k = 10 \text{ W/m}^2\cdot\text{K} \times 0.2 \text{ m}/2 \text{ W/m}\cdot\text{K} = 1$, find
 - Node 7: $(2T_5 + 300 + T_8) + 2 \times 1 \cdot 100 - 2(1+2)T_7 = 0$
 - Node 8: $(2T_6 + T_7 + T_7) + 2 \times 1 \cdot 100 - 2(1+2)T_8 = 0$

The solution matrix [T] can be found using a stock matrix program using the [A] and [C] matrices shown below to obtain the solution matrix [T] (Eq. 4.48). Alternatively, the set of equations could be entered into the IHT workspace and solved for the nodal temperatures.

$$A = \begin{bmatrix} -4 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 2 & -4 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & -4 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 2 & -4 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & -4 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 2 & -4 & 0 & 1 \\ 0 & 0 & 0 & 0 & 2 & 0 & -6 & 1 \\ 0 & 0 & 0 & 0 & 0 & 2 & 2 & -6 \end{bmatrix} \quad C = \begin{bmatrix} -600 \\ -300 \\ -300 \\ 0 \\ -300 \\ 0 \\ -500 \\ -200 \end{bmatrix} \quad T = \begin{bmatrix} 292.2 \\ 289.2 \\ 279.7 \\ 272.2 \\ 254.5 \\ 240.1 \\ 198.1 \\ 179.4 \end{bmatrix}$$

From the solution matrix, [T], find the mid-point temperature as

$$T_4 = 272.2^\circ\text{C}$$

<

Continued...

PROBLEM 4.52 (Cont.)

The heat rate by convection between the bar and fluid is given as,

$$q'_{\text{conv}} = 2(q'_a + q'_b + q'_c)$$

$$q'_{\text{conv}} = 2 \left[h(\Delta x/2)(T_8 - T_\infty) + h(\Delta x)(T_7 - T_\infty) + h(\Delta x/2)(300 - T_\infty) \right]$$

$$q'_{\text{conv}} = 2 \left[10 \text{ W/m}^2 \cdot \text{K} \times (0.2 \text{ m}/2) \left[(179.4 - 100) + 2(198.1 - 100) + (300 - 100) \right] \text{ K} \right]$$

$$q'_{\text{conv}} = 952 \text{ W/m}.$$

<

(b) Reducing the grid spacing by a factor of 2, the nodal arrangement will appear as shown. The finite-difference equation for the interior and centerline nodes were written by inspection and entered into the IHT workspace. The *IHT Finite-Difference Equations Tool* for 2-D, SS conditions, was used to obtain the FDE for the nodes on the exposed surface.

The midpoint temperature T_{13} and heat rate for the finer mesh are

$$T_{13} = 271.0^\circ\text{C} \quad q' = 834 \text{ W/m}$$

<

COMMENTS: The midpoint temperatures for the coarse and finer meshes agree closely, $T_4 = 272^\circ\text{C}$ vs. $T_{13} = 271.0^\circ\text{C}$, respectively. However, the estimate for the heat rate is substantially influenced by the mesh size; $q' = 952$ vs. 834 W/m for the coarse and finer meshes, respectively.

PROBLEM 4.53

KNOWN: Volumetric heat generation in a rectangular rod of uniform surface temperature.

FIND: (a) Temperature distribution in the rod, and (b) With boundary conditions unchanged, heat generation rate causing the midpoint temperature to reach 600 K.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) Uniform volumetric heat generation.

ANALYSIS: (a) From symmetry it follows that six unknown temperatures must be determined. Since all nodes are interior ones, the finite-difference equations may be obtained from Eq. 4.35 written in the form

$$T_i = 1/4 \sum T_{\text{neighbors}} + 1/4 (\dot{q} (\Delta x \Delta y) / k).$$

With $\dot{q} (\Delta x \Delta y) / 4k = 62.5$ K, the system of finite-difference equations is

$$T_1 = 0.25(T_s + T_2 + T_4 + T_s) + 15.625 \quad (1)$$

$$T_2 = 0.25(T_s + T_3 + T_5 + T_1) + 15.625 \quad (2)$$

$$T_3 = 0.25(T_s + T_2 + T_6 + T_2) + 15.625 \quad (3)$$

$$T_4 = 0.25(T_1 + T_5 + T_1 + T_s) + 15.625 \quad (4)$$

$$T_5 = 0.25(T_2 + T_6 + T_2 + T_4) + 15.625 \quad (5)$$

$$T_6 = 0.25(T_3 + T_5 + T_3 + T_5) + 15.625 \quad (6)$$

With $T_s = 300$ K, the set of equations was written directly into the IHT workspace and solved for the nodal temperatures,

T_1	T_2	T_3	T_4	T_5	T_6 (K)
348.6	368.9	374.6	362.4	390.2	398.0

<

(b) With the boundary conditions unchanged, the \dot{q} required for $T_6 = 600$ K can be found using the same set of equations in the IHT workspace, but with these changes: (1) replace the last term on the RHS (15.625) of Eqs. (1-6) by $\dot{q} (\Delta x \Delta y) / 4k = (0.005 \text{ m})^2 \dot{q} / 4 \times 20 \text{ W/m} \cdot \text{K} = 3.125 \times 10^{-7} \dot{q}$ and (2) set $T_6 = 600$ K. The set of equations has 6 unknown, five nodal temperatures plus \dot{q} . Solving find

$$\dot{q} = 1.53 \times 10^8 \text{ W/m}^3$$

<

PROBLEM 4.54

KNOWN: Flue of square cross section with prescribed geometry, thermal conductivity and inner and outer surface temperatures.

FIND: Heat loss per unit length from the flue, q' .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) No internal generation.

ANALYSIS: Taking advantage of symmetry, the nodal network using the suggested 75mm grid spacing is shown above. To obtain the heat rate, we first need to determine the unknown temperatures T_1 , T_2 , T_3 and T_4 . Recognizing that these nodes may be treated as interior nodes, the nodal equations from Eq. 4.29 are

$$(T_2 + 25 + T_2 + 350) - 4T_1 = 0$$

$$(T_1 + 25 + T_3 + 350) - 4T_2 = 0$$

$$(T_2 + 25 + T_4 + 350) - 4T_3 = 0$$

$$(T_3 + 25 + 25 + T_3) - 4T_4 = 0.$$

The Gauss-Seidel iteration method is convenient for this system of equations and following the procedures of Section 4.5.2, they are rewritten as,

$$T_1^k = 0.50 T_2^{k-1} + 93.75$$

$$T_2^k = 0.25 T_1^k + 0.25 T_3^{k-1} + 93.75$$

$$T_3^k = 0.25 T_2^k + 0.25 T_4^{k-1} + 93.75$$

$$T_4^k = 0.50 T_3^k + 12.5.$$

The iteration procedure is implemented in the table on the following page, one row for each iteration k . The initial estimates, for $k = 0$, are all chosen as $(350 + 25)/2 \approx 185^\circ\text{C}$. Iteration is continued until the maximum temperature difference is less than 0.2°C , i.e., $\varepsilon < 0.2^\circ\text{C}$.

Note that if the system of equations were organized in matrix form, Eq. 4.48, diagonal dominance would exist. Hence there is no need to reorder the equations since the magnitude of the diagonal element is greater than that of other elements in the same row.

Continued

PROBLEM 4.54 (Cont.)

k	$T_1(^{\circ}\text{C})$	$T_2(^{\circ}\text{C})$	$T_3(^{\circ}\text{C})$	$T_4(^{\circ}\text{C})$	
0	185	185	185	185	← initial estimate
1	186.3	186.6	186.6	105.8	
2	187.1	187.2	167.0	96.0	
3	187.4	182.3	163.3	94.2	
4	184.9	180.8	162.5	93.8	
5	184.2	180.4	162.3	93.7	
6	184.0	180.3	162.3	93.6	
7	183.9	180.3	162.2	93.6	← $\varepsilon < 0.2^{\circ}\text{C}$

From knowledge of the temperature distribution, the heat rate may be obtained by summing the heat rates across the nodal control volume surfaces, as shown in the sketch.

The heat rate leaving the outer surface of this flue section is,

$$\begin{aligned}
 q' &= q'_a + q'_b + q'_c + q'_d + q'_e \\
 q' &= k \frac{\Delta x}{\Delta y} \left[\frac{1}{2} (T_1 - 25) + (T_2 - 25) + (T_3 - 25) + (T_4 - 25) + 0 \right] \\
 q' &= 0.85 \frac{\text{W}}{\text{m} \cdot \text{K}} \left[\frac{1}{2} (183.9 - 25) + (180.3 - 25) + (162.2 - 26) + (93.6 - 25) \right] \\
 q' &= 374.5 \text{ W/m.}
 \end{aligned}$$

Since this flue section is 1/8 the total cross section, the total heat loss from the flue is

$$q' = 8 \times 374.5 \text{ W/m} = 3.00 \text{ kW/m.}$$

<

COMMENTS: The heat rate could have been calculated at the inner surface, and from the above sketch has the form

$$q' = k \frac{\Delta x}{\Delta y} \left[\frac{1}{2} (350 - T_1) + (350 - T_2) + (350 - T_3) \right] = 374.5 \text{ W/m.}$$

This result should compare very closely with that found for the outer surface since the conservation of energy requirement must be satisfied in obtaining the nodal temperatures.

PROBLEM 4.55

KNOWN: Flue of square cross section with prescribed geometry, thermal conductivity and inner and outer surface convective conditions.

FIND: (a) Heat loss per unit length, q' , by convection to the air, (b) Effect of grid spacing and convection coefficients on temperature field; show isotherms.

SCHEMATIC:

Schematic (a)

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Taking advantage of symmetry, the nodal network for a 75 mm grid spacing is shown in schematic (a). To obtain the heat rate, we need first to determine the temperatures T_i . Recognize that there are four types of nodes: interior (4-7), plane surface with convection (1, 2, 8-11), internal corner with convection (3), and external corner with convection (12). Using the appropriate relations from Table 4.2, the finite-difference equations are

Node	Equation
1	$(2T_4 + T_2 + T_2) + \frac{2h_i\Delta x}{k}T_{\infty,i} - 2\left(\frac{h_i\Delta x}{k} + 2\right)T_1 = 0$ 4.42
2	$(2T_5 + T_3 + T_1) + \frac{2h_i\Delta x}{k}T_{\infty,i} - 2\left(\frac{h_i\Delta x}{k} + 2\right)T_2 = 0$ 4.42
3	$2(T_6 + T_6) + (T_2 + T_2) + \frac{2h_i\Delta x}{k}T_{\infty,i} - 2\left(3 + \frac{h_i\Delta x}{k}\right)T_3 = 0$ 4.41
4	$(T_8 + T_5 + T_1 + T_5) - 4T_4 = 0$ 4.29
5	$(T_9 + T_6 + T_2 + T_4) - 4T_5 = 0$ 4.29
6	$(T_{10} + T_7 + T_3 + T_5) - 4T_6 = 0$ 4.29
7	$(T_{11} + T_{11} + T_6 + T_6) - 4T_7 = 0$ 4.29
8	$(2T_4 + T_9 + T_9) + \frac{2h_o\Delta x}{k}T_{\infty,o} - 2\left(\frac{h_o\Delta x}{k} + 2\right)T_8 = 0$ 4.42
9	$(2T_5 + T_{10} + T_8) + \frac{2h_o\Delta x}{k}T_{\infty,o} - 2\left(\frac{h_o\Delta x}{k} + 2\right)T_9 = 0$ 4.42
10	$(2T_6 + T_{11} + T_9) + \frac{2h_o\Delta x}{k}T_{\infty,o} - 2\left(\frac{h_o\Delta x}{k} + 2\right)T_{10} = 0$ 4.42
11	$(2T_7 + T_{12} + T_{10}) + \frac{2h_o\Delta x}{k}T_{\infty,o} - 2\left(\frac{h_o\Delta x}{k} + 2\right)T_{11} = 0$ 4.42
12	$(T_{11} + T_{11}) + \frac{2h_o\Delta x}{k}T_{\infty,o} - 2\left(\frac{h_o\Delta x}{k} + 1\right)T_{12} = 0$ 4.43

Continued...

PROBLEM 4.55 (Cont.)

The Gauss-Seidel iteration is convenient for this system of equations. Following procedures of Section 4.5.2, the system of equations is rewritten in the proper form. Note that diagonal dominance is present; hence, no re-ordering is necessary.

$$\begin{aligned}
 T_1^k &= 0.09239T_2^{k-1} + 0.09239T_4^{k-1} + 285.3 \\
 T_2^k &= 0.04620T_1^k + 0.04620T_3^{k-1} + 0.09239T_5^{k-1} + 285.3 \\
 T_3^k &= 0.08457T_2^k + 0.1692T_6^{k-1} + 261.2 \\
 T_4^k &= 0.25T_1^k + 0.50T_5^{k-1} + 0.25T_8^{k-1} \\
 T_5^k &= 0.25T_2^k + 0.25T_4^k + 0.25T_6^{k-1} + 0.25T_9^{k-1} \\
 T_6^k &= 0.25T_3^k + 0.25T_5^k + 0.25T_7^{k-1} + 0.25T_9^{k-1} \\
 T_7^k &= 0.50T_6^k + 0.50T_{11}^{k-1} \\
 T_8^k &= 0.4096T_4^k + 0.4096T_9^{k-1} + 4.52 \\
 T_9^k &= 0.4096T_5^k + 0.2048T_8^k + 0.2048T_{10}^{k-1} + 4.52 \\
 T_{10}^k &= 0.4096T_6^k + 0.2048T_9^k + 0.2048T_{11}^{k-1} + 4.52 \\
 T_{11}^k &= 0.4096T_7^k + 0.2048T_{10}^k + 0.2048T_{12}^{k-1} + 4.52 \\
 T_{12}^k &= 0.6939T_{11}^k + 7.65
 \end{aligned}$$

The initial estimates ($k = 0$) are carefully chosen to minimize calculation labor; let $\varepsilon < 1.0$.

k	T ₁	T ₂	T ₃	T ₄	T ₅	T ₆	T ₇	T ₈	T ₉	T ₁₀	T ₁₁	T ₁₂
0	340	330	315	250	225	205	195	160	150	140	125	110

3	338.8	338.4	328.2	247.7	245.7	230.6	180.5	175.6	173.7	161.2	131.6	98.9
4	339.4	338.8	328.9	251.6	248.7	232.9	182.3	178.7	176.0	162.9	132.8	99.8
5	339.8	339.2	329.3	254.0	250.5	234.5	183.7	180.6	177.5	164.1	133.8	100.5
6	340.1	339.4	329.7	255.4	251.7	235.7	184.7	181.8	178.5	164.7	134.5	101.0
7	340.3	339.5	329.9	256.4	252.5	236.4	185.5	182.7	179.1	165.6	135.1	101.4

The heat loss to the outside air for the upper surface (Nodes 8 through 12) is of the form

$$\begin{aligned}
 q' &= h_o \Delta x \left[\frac{1}{2} (T_8 - T_{\infty,o}) + (T_9 - T_{\infty,o}) + (T_{10} - T_{\infty,o}) + (T_{11} - T_{\infty,o}) + \frac{1}{2} (T_{12} - T_{\infty,o}) \right] \\
 q' &= 5 \text{ W/m}^2 \cdot \text{K} \times 0.075 \text{ m} \left[\frac{1}{2} (182.7 - 25) + (179.1 - 25) + (165.6 - 25) + (135.1 - 25) + \frac{1}{2} (101.4 - 25) \right] ^\circ\text{C} = 195 \text{ W/m}
 \end{aligned}$$

Hence, for the entire flue cross-section, considering symmetry,

$$q'_{\text{tot}} = 8 \times q' = 8 \times 195 \text{ W/m} = 1.57 \text{ kW/m} \quad \leftarrow$$

The convection heat rate at the inner surface is

$$q'_{\text{tot}} = 8 \times h_i \Delta x \left[\frac{1}{2} (T_{\infty,i} - T_1) + (T_{\infty,i} - T_2) + \frac{1}{2} (T_{\infty,i} - T_3) \right] = 8 \times 190.5 \text{ W/m} = 1.52 \text{ kW/m}$$

which is within 2.5% of the foregoing result. The calculation would be identical if $\varepsilon = 0$.

Continued...

PROBLEM 4.55 (Cont.)

(b) Using the *Finite-Difference Equations* option from the *Tools* portion of the IHT menu, the following two-dimensional temperature field was computed for the grid shown in the schematic below, where x and y are in mm and the temperatures are in $^{\circ}\text{C}$.

y\x	0	25	50	75	100	125	150	175	200	225	250	275	300
0	180.7	180.2	178.4	175.4	171.1	165.3	158.1	149.6	140.1	129.9	119.4	108.7	98.0
25	204.2	203.6	201.6	198.2	193.3	186.7	178.3	168.4	157.4	145.6	133.4	121.0	
50	228.9	228.3	226.2	222.6	217.2	209.7	200.1	188.4	175.4	161.6	147.5		
75	255.0	254.4	252.4	248.7	243.1	235.0	223.9	209.8	194.1	177.8			
100	282.4	281.8	280.1	276.9	271.6	263.3	250.5	232.8	213.5				
125	310.9	310.5	309.3	307.1	303.2	296.0	282.2	257.5					
150	340.0	340.0	339.6	339.1	337.9	335.3	324.7						

Agreement between the temperature fields for the (a) and (b) grids is good, with the largest differences occurring at the interior and exterior corners. Ten isotherms generated using *FEHT* are shown on the symmetric section below. Note how the heat flow is nearly normal to the flue wall around the mid-section. In the corner regions, the isotherms are curved and we'd expect that grid size might influence the accuracy of the results. Convection heat transfer to the inner surface is

$$q' = 8h_i\Delta x \left[\frac{(T_{\infty,i} - T_1)}{2} + (T_{\infty,i} - T_2) + (T_{\infty,i} - T_3) + (T_{\infty,i} - T_4) \right. \\ \left. + (T_{\infty,i} - T_5) + (T_{\infty,i} - T_6) + \frac{(T_{\infty,i} - T_7)}{2} \right] = 1.52 \text{ kW/m}$$

and the agreement with results of the coarse grid is excellent.

The heat rate increases with increasing h_i and h_o , while temperatures in the wall increase and decrease, respectively, with increasing h_i and h_o .

PROBLEM 4.56

KNOWN: Rectangular air ducts having surfaces at 80°C in a concrete slab with an insulated bottom and upper surface maintained at 30°C .

FIND: Heat rate from each duct per unit length of duct, q' .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) No internal volumetric generation, (4) Constant properties.

PROPERTIES: Concrete (given): $k = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: Taking advantage of symmetry, the nodal network, using the suggested grid spacing

$$\Delta x = 2\Delta y = 37.50 \text{ mm}$$

$$\Delta y = 0.125L = 18.75 \text{ mm}$$

where $L = 150 \text{ mm}$, is shown in the sketch. To

evaluate the heat rate, we need the temperatures T_1 ,

T_2 , T_3 , T_4 , and T_5 . All the nodes may be treated as interior nodes (considering symmetry for those nodes on insulated boundaries), Eq. 4.29. Use matrix notation, Eq. 4.48, $[A][T] = [C]$, and perform the inversion.

The heat rate per unit length from the prescribed section of the duct follows from an energy balance on the nodes at the top isothermal surface.

$$q' = q'_1 + q'_2 + q'_3 + q'_4 + q'_5$$

$$q' = k(\Delta x/2) \frac{T_1 - T_s}{\Delta y} + k \cdot \Delta x \frac{T_2 - T_s}{\Delta y} + k \cdot \Delta x \frac{T_3 - T_s}{\Delta y} + k \cdot \Delta x \frac{T_4 - T_s}{\Delta y} + k(\Delta x/2) \frac{T_5 - T_s}{\Delta y}$$

$$q' = k[(T_1 - T_s) + 2(T_2 - T_s) + 2(T_3 - T_s) + 2(T_4 - T_s) + (T_5 - T_s)]$$

$$q' = 1.4 \text{ W/m}\cdot\text{K}[(41.70 - 30) + 2(44.26 - 30) + 2(53.92 - 30) + 2(54.89 - 30) + (54.98 - 30)]$$

$$q' = 228 \text{ W/m}$$

Since the section analyzed represents one-half of the region about an air duct, the heat loss per unit length for each duct is,

$$q'_{\text{duct}} = 2 \times q' = 456 \text{ W/m}.$$

PROBLEM 4.57

KNOWN: Dimensions and operating conditions for a gas turbine blade with embedded channels.

FIND: Effect of applying a zirconia, thermal barrier coating.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) Negligible radiation.

ANALYSIS: Preserving the nodal network of Example 4.4 and adding surface nodes for the TBC, finite-difference equations previously developed for nodes 7 through 21 are still appropriate, while new equations must be developed for nodes 1c-6c, 1o-6o, and 1i-6i. Considering node 3c as an example, an energy balance yields

$$h_o \Delta x (T_{\infty,o} - T_{3c}) + \frac{k_c (\Delta y_c / 2)}{\Delta x} (T_{2c} - T_{3c}) + \frac{k_c (\Delta y_c / 2)}{\Delta x} (T_{4c} - T_{3c}) + \frac{k_c \Delta x}{\Delta y_c} (T_{3o} - T_{3c}) = 0$$

or, with $\Delta x = 1 \text{ mm}$ and $\Delta y_c = 0.5 \text{ mm}$,

$$0.25(T_{2c} + T_{4c}) + 2T_{3o} - \left(2.5 + \frac{h_o \Delta x}{k_c} \right) T_{3c} = -\frac{h_o \Delta x}{k_c} T_{\infty,o}$$

Similar expressions may be obtained for the other 5 nodal points on the outer surface of the TBC.

Applying an energy balance to node 3o at the inner surface of the TBC, we obtain

$$\frac{k_c \Delta x}{\Delta y_c} (T_{3c} - T_{3o}) + \frac{k_c (\Delta y_c / 2)}{\Delta x} (T_{2o} - T_{3o}) + \frac{k_c (\Delta y_c / 2)}{\Delta x} (T_{4o} - T_{3o}) + \frac{\Delta x}{R''_{t,c}} (T_{3i} - T_{3o}) = 0$$

or,

$$2T_{3c} + 0.25(T_{2o} + T_{4o}) + \frac{\Delta x}{k_c R''_{t,c}} T_{3i} - \left(2.5 + \frac{\Delta x}{k_c R''_{t,c}} \right) T_{3o} = 0$$

Similar expressions may be obtained for the remaining nodal points on the inner surface of the TBC (outer region of the contact resistance).

Continued...

PROBLEM 4.57 (Cont.)

Applying an energy balance to node 3i at the outer surface of the turbine blade, we obtain

$$\frac{\Delta x}{R''_{t,c}}(T_{3o} - T_{3i}) + \frac{k(\Delta y/2)}{\Delta x}(T_{2i} - T_{3i}) + \frac{k(\Delta y/2)}{\Delta x}(T_{4i} - T_{3i}) + \frac{k\Delta x}{\Delta y}(T_9 - T_{3i}) = 0$$

or,

$$\frac{\Delta x}{kR''_{t,c}}T_{3o} + 0.5(T_{2,i} + T_{4,i}) + T_9 - \left(2 + \frac{\Delta x}{kR''_{t,c}}\right)T_{3i} = 0$$

Similar expressions may be obtained for the remaining nodal points on the inner region of the contact resistance.

The 33 finite-difference equations were entered into the workspace of IHT from the keyboard, and for $h_o = 1000 \text{ W/m}^2\cdot\text{K}$, $T_{\infty,o} = 1700 \text{ K}$, $h_i = 200 \text{ W/m}^2\cdot\text{K}$ and $T_{\infty,i} = 400 \text{ K}$, the following temperature field was obtained, where coordinate (x,y) locations are in mm and temperatures are in °C.

y\x	0	1	2	3	4	5
0	1536	1535	1534	1533	1533	1532
0.5	1473	1472	1471	1469	1468	1468
0.5	1456	1456	1454	1452	1451	1451
1.5	1450	1450	1447	1446	1444	1444
2.5	1446	1445	1441	1438	1437	1436
3.5	1445	1443	1438	0	0	0

Note the significant reduction in the turbine blade temperature, as, for example, from a surface temperature of $T_1 = 1526 \text{ K}$ without the TBC to $T_{1i} = 1456 \text{ K}$ with the coating. Hence, the coating is serving its intended purpose.

COMMENTS: (1) Significant additional benefits may still be realized by increasing h_i . (2) The foregoing solution may be used to determine the temperature field without the TBC by setting $k_c \rightarrow \infty$ and $R''_{t,c} \rightarrow 0$.

PROBLEM 4.58

KNOWN: Bar of rectangular cross-section subjected to prescribed boundary conditions.

FIND: Using a numerical technique with a grid spacing of 0.1m, determine the temperature distribution and the heat transfer rate from the bar to the fluid.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: The nodal network has $\Delta x = \Delta y = 0.1\text{m}$. Note the adiabat corresponding to system symmetry. The finite-difference equations for each node can be written using either Eq. 4.29, for interior nodes, or Eq. 4.42, for a plane surface with convection. In the case of adiabatic surfaces, Eq. 4.42 is used with $h = 0$. Note that

$$\frac{h\Delta x}{k} = \frac{50\text{W/m}^2 \cdot \text{K} \times 0.1\text{m}}{1.5\text{W/m} \cdot \text{K}} = 3.333.$$

Node	Finite-Difference Equations
1	$-4T_1 + 2T_2 + 2T_4 = 0$
2	$-4T_2 + T_1 + T_3 + 2T_5 = 0$
3	$-4T_3 + 200 + 2T_6 + T_2 = 0$
4	$-4T_4 + T_1 + 2T_5 + T_7 = 0$
5	$-4T_5 + T_2 + T_6 + T_8 + T_4 = 0$
6	$-4T_6 + T_5 + T_3 + 200 + T_9 = 0$
7	$-4T_7 + T_4 + 2T_8 + T_{10} = 0$
8	$-4T_8 + T_7 + T_5 + T_9 + T_{11} = 0$
9	$-4T_9 + T_8 + T_6 + 200 + T_{12} = 0$
10	$-4T_{10} + T_7 + 2T_{11} + T_{13} = 0$
11	$-4T_{11} + T_{10} + T_8 + T_{12} + T_{14} = 0$
12	$-4T_{12} + T_{11} + T_9 + 200 + T_{15} = 0$
13	$2T_{10} + T_{14} + 6.666 \times 30 - 10.666 T_{13} = 0$
14	$2T_{11} + T_{13} + T_{15} + 6.666 \times 30 - 2(3.333 + 2)T_{14} = 0$
15	$2T_{12} + T_{14} + 200 + 6.666 \times 30 - 2(3.333 + 2)T_{15} = 0$

Using the matrix inversion method, Section 4.5.2, the above equations can be written in the form $[A][T] = [C]$ where $[A]$ and $[C]$ are shown on the next page. Using a stock matrix inversion routine, the temperatures $[T]$ are determined.

Continued

PROBLEM 4.58 (Cont.)

$$[A] = \begin{bmatrix} -4 & 2 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & -4 & 1 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & -4 & 0 & 0 & -2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & -4 & 2 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & -4 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & -4 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & -4 & 2 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 & -4 & 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & -4 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & -4 & 2 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & -1 & -4 & 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & -4 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & -10.66 & 2 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 1 & -10.66 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 1 & -10.66 \end{bmatrix}$$

$$[C] = \begin{bmatrix} 0 \\ 0 \\ -200 \\ 0 \\ 0 \\ -200 \\ 0 \\ 0 \\ -200 \\ 0 \\ 0 \\ -200 \\ -200 \\ -200 \\ -400 \end{bmatrix} \quad [T] = \begin{bmatrix} T_1 \\ T_2 \\ T_3 \\ T_4 \\ T_5 \\ T_6 \\ T_7 \\ T_8 \\ T_9 \\ T_{10} \\ T_{11} \\ T_{12} \\ T_{13} \\ T_{14} \\ T_{15} \end{bmatrix} = \begin{bmatrix} 153.9 \\ 159.7 \\ 176.4 \\ 148.0 \\ 154.4 \\ 172.9 \\ 129.4 \\ 137.0 \\ 160.7 \\ 95.6 \\ 103.5 \\ 132.8 \\ 45.8 \\ 48.7 \\ 67.0 \end{bmatrix} (^\circ\text{C})$$

Considering symmetry, the heat transfer rate to the fluid is twice the convection rate from the surfaces of the control volumes exposed to the fluid. Using Newton's law of cooling, considering a unit thickness of the bar, find

$$q_{\text{conv}} = 2 \left[h \cdot \frac{\Delta y}{2} \cdot (T_{13} - T_\infty) + h \cdot \Delta y \cdot (T_{14} - T_\infty) + h \cdot \Delta y (T_{15} - T_\infty) + h \cdot \frac{\Delta y}{2} (200 - T_\infty) \right]$$

$$q_{\text{conv}} = 2h \cdot \Delta y \left[\frac{1}{2} (T_{13} - T_\infty) + (T_{14} - T_\infty) + (T_{15} - T_\infty) + \frac{1}{2} (200 - T_\infty) \right]$$

$$q_{\text{conv}} = 2 \times 50 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times 0.1 \text{ m} \left[\frac{1}{2} (45.8 - 30) + (48.7 - 30) + (67.0 - 30) + \frac{1}{2} (200 - 30) \right]$$

$$q_{\text{conv}} = 1487 \text{ W/m.}$$

<

PROBLEM 4.59

KNOWN: Upper surface and grooves of a plate are maintained at a uniform temperature T_1 , while the lower surface is maintained at T_2 or is exposed to a fluid at T_∞ .

FIND: (a) Heat rate per width of groove spacing (w) for isothermal top and bottom surfaces using a finite-difference method with $\Delta x = 40$ mm, (b) Effect of grid spacing and convection at bottom surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Using a space increment of $\Delta x = 40$ mm, the symmetrical section shown in schematic (b) corresponds to one-half the groove spacing. There exist only two interior nodes for which finite-difference equations must be written.

$$\begin{aligned} \text{Node } a: \quad & 4T_a - (T_1 + T_b + T_2 + T_1) = 0 \\ & 4T_a - (200 + T_b + 20 + 200) = 0 \quad \text{or} \quad 4T_a - T_b = 420 \end{aligned} \quad (1)$$

$$\begin{aligned} \text{Node } b: \quad & 4T_b - (T_1 + T_a + T_2 + T_a) = 0 \\ & 4T_b - (200 + 2T_a + 20) = 0 \quad \text{or} \quad -2T_a + 4T_b = 220 \end{aligned} \quad (2)$$

Multiply Eq. (2) by 2 and add to Eq. (1) to obtain

$$7T_b = 860 \quad \text{or} \quad T_b = 122.9^\circ\text{C}$$

From Eq. (1),

$$4T_a - 122.9 = 420 \quad \text{or} \quad T_a = (420 + 122.9)/4 = 135.7^\circ\text{C}.$$

The heat transfer through the symmetrical section is equal to the sum of heat flows through control volumes adjacent to the lower surface. From the schematic,

$$q' = q'_1 + q'_2 + q'_3 = k \left(\frac{\Delta x}{2} \right) \frac{T_1 - T_2}{\Delta y} + k (\Delta x) \frac{T_a - T_2}{\Delta y} + k \left(\frac{\Delta x}{2} \right) \frac{T_b - T_2}{\Delta y}.$$

Continued...

PROBLEM 4.59 (Cont.)

Noting that $\Delta x = \Delta y$, regrouping and substituting numerical values, find

$$q' = k \left[\frac{1}{2}(T_1 - T_2) + (T_a - T_2) + \frac{1}{2}(T_b - T_2) \right]$$

$$q' = 15 \text{ W/m} \cdot \text{K} \left[\frac{1}{2}(200 - 20) + (135.7 - 20) + \frac{1}{2}(122.9 - 20) \right] = 3.86 \text{ kW/m}.$$

For the full groove spacing, $q'_{\text{total}} = 2 \times 3.86 \text{ kW/m} = 7.72 \text{ kW/m}$.

(b) Using the *Finite-Difference Equations* option from the *Tools* portion of the IHT menu, the following two-dimensional temperature field was computed for the grid shown in schematic (b), where x and y are in mm and the nodal temperatures are in $^{\circ}\text{C}$. Nodes 2-54 are interior nodes, with those along the symmetry adiabats characterized by $T_{m-1,n} = T_{m+1,n}$, while nodes 55-63 lie on a plane surface.

10				200	191	186.6	184.3	183.1	182.8
20			200	186.7	177.2	171.2	167.5	165.5	164.8
30		200	182.4	169.5	160.1	153.4	149.0	146.4	145.5
40	200	175.4	160.3	148.9	140.1	133.5	128.7	125.7	124.4
50	141.4	134.3	125.7	118.0	111.6	106.7	103.1	100.9	100.1
60	97.09	94.62	90.27	85.73	81.73	78.51	76.17	74.73	74.24
70	57.69	56.83	55.01	52.95	51.04	49.46	48.31	47.60	47.36
80	20	20	20	20	20	20	20	20	20

The foregoing results were computed for $h = 10^7 \text{ W/m}^2 \cdot \text{K}$ ($h \rightarrow \infty$) and $T_{\infty} = 20^{\circ}\text{C}$, which is tantamount to prescribing an isothermal bottom surface at 20°C . Agreement between corresponding results for the coarse and fine grids is surprisingly good ($T_a = 135.7^{\circ}\text{C} \leftrightarrow T_{23} = 140.1^{\circ}\text{C}$; $T_b = 122.9^{\circ}\text{C} \leftrightarrow T_{27} = 124.4^{\circ}\text{C}$). The heat rate is

$$q' = 2 \times k \left[(T_{46} - T_{55})/2 + (T_{47} - T_{56}) + (T_{48} - T_{57}) + (T_{49} - T_{58}) + (T_{50} - T_{59}) \right. \\ \left. + (T_{51} - T_{60}) + (T_{52} - T_{61}) + (T_{53} - T_{62}) + (T_{54} - T_{63})/2 \right]$$

$$q' = 2 \times 15 \text{ W/m} \cdot \text{K} [18.84 + 36.82 + 35.00 + 32.95 + 31.04 + 29.46 \\ + 28.31 + 27.6 + 13.68]^{\circ}\text{C} = 7.61 \text{ kW/m}$$

The agreement with $q' = 7.72 \text{ kW/m}$ from the coarse grid of part (a) is excellent and a fortuitous consequence of compensating errors. With reductions in the convection coefficient from $h \rightarrow \infty$ to $h = 1000, 200$ and $5 \text{ W/m}^2 \cdot \text{K}$, the corresponding increase in the thermal resistance reduces the heat rate to values of 6.03, 3.28 and 0.14 kW/m , respectively. With decreasing h , there is an overall increase in nodal temperatures, as, for example, from 191°C to 199.8°C for T_2 and from 20°C to 196.9°C for T_{55} .

NOTE TO INSTRUCTOR: To reduce computational effort, while achieving the same educational objectives, the problem statement has been changed to allow for convection at the bottom, rather than the top, surface.

PROBLEM 4.60

KNOWN: Rectangular plate subjected to uniform temperature boundaries.

FIND: Temperature at the midpoint using a finite-difference method with space increment of 0.25m

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: For the nodal network above, 12 finite-difference equations must be written. It follows that node 8 represents the midpoint of the rectangle. Since all nodes are interior nodes, Eq. 4.29 is appropriate and is written in the form

$$4T_m - \sum T_{\text{neighbors}} = 0.$$

For nodes on the symmetry adiabat, the neighboring nodes include two symmetrical nodes. Hence, for Node 4, the neighbors are T_b , T_8 and $2T_3$. Because of the simplicity of the finite-difference equations, we may proceed directly to the matrices $[A]$ and $[C]$ – see Eq. 4.48 – and matrix inversion can be used to find the nodal temperatures T_m .

$$A = \begin{bmatrix} -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 2 & -4 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 2 & -4 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & -4 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & -4 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & -4 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 2 & -4 \end{bmatrix}$$

$$C = \begin{bmatrix} -200 \\ -150 \\ -150 \\ -150 \\ -50 \\ 0 \\ 0 \\ 0 \\ 0 \\ -100 \\ -50 \\ -50 \\ -50 \end{bmatrix}$$

$$T = \begin{bmatrix} 96.5 \\ 112.9 \\ 118.9 \\ 120.4 \\ 73.2 \\ 86.2 \\ 92.3 \\ 94.0 \\ 59.9 \\ 65.5 \\ 69.9 \\ 71.0 \end{bmatrix}$$

The temperature at the midpoint (Node 8) is

$$T(1, 0.5) = T_8 = 94.0^\circ\text{C}.$$

<

COMMENTS: Using the exact analytical, solution – see Eq. 4.19 and Problem 4.2 – the midpoint temperature is found to be 94.5°C . To improve the accuracy of the finite-difference method, it would be necessary to decrease the nodal mesh size.

PROBLEM 4.61

KNOWN: Long bar with trapezoidal shape, uniform temperatures on two surfaces, and two insulated surfaces.

FIND: Heat transfer rate per unit length using finite-difference method with space increment of 10mm.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: The heat rate can be found after the temperature distribution has been determined. Using the nodal network shown above with $\Delta x = 10\text{mm}$, nine finite-difference equations must be written. Nodes 1-4 and 6-8 are interior nodes and their finite-difference equations can be written directly from Eq. 4.29. For these nodes

$$T_{m,n+1} + T_{m,n-1} + T_{m+1,n} + T_{m-1,n} - 4T_{m,n} = 0 \quad m = 1-4, 6-8. \quad (1)$$

For nodes 5 and 9 located on the diagonal, insulated boundary, the appropriate finite-difference equation follows from an energy balance on the control volume shown above (upper-right corner of schematic), $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = q_a + q_b = 0$

$$k(\Delta y \cdot 1) \frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k(\Delta x \cdot 1) \frac{T_{m,n-1} - T_{m,n}}{\Delta y} = 0.$$

Since $\Delta x = \Delta y$, the finite-difference equation for nodes 5 and 9 is of the form

$$T_{m-1,n} + T_{m,n-1} - 2T_{m,n} = 0 \quad m = 5, 9. \quad (2)$$

The system of 9 finite-difference equations is first written in the form of Eqs. (1) or (2) and then written in explicit form for use with the Gauss-Seidel iteration method of solution; see Section 4.5.2.

Node	Finite-difference equation	Gauss-Seidel form
1	$T_2 + T_6 + 100 - 4T_1 = 0$	$T_1 = 0.5T_2 + 0.25T_6 + 25$
2	$T_3 + T_7 + 100 - 4T_2 = 0$	$T_2 = 0.25(T_1 + T_3 + T_7) + 25$
3	$T_4 + T_8 + 100 - 4T_3 = 0$	$T_3 = 0.25(T_2 + T_4 + T_8) + 25$
4	$T_5 + T_9 + 100 - 4T_4 = 0$	$T_4 = 0.25(T_3 + T_5 + T_9) + 25$
5	$100 + T_4 - 2T_5 = 0$	$T_5 = 0.5T_4 + 50$
6	$T_7 + T_2 + 25 - 4T_6 = 0$	$T_6 = 0.25T_1 + 0.5T_7 + 6.25$
7	$T_8 + T_6 + 25 - 4T_7 = 0$	$T_7 = 0.25(T_2 + T_6 + T_8) + 6.25$
8	$T_9 + T_7 + 25 - 4T_8 = 0$	$T_8 = 0.25(T_3 + T_7 + T_9) + 6.25$
9	$T_4 + T_8 - 2T_9 = 0$	$T_9 = 0.5(T_4 + T_8)$

Continued

PROBLEM 4.61 (Cont.)

The iteration process begins after an initial guess ($k = 0$) is made. The calculations are shown in the table below.

k	T ₁	T ₂	T ₃	T ₄	T ₅	T ₆	T ₇	T ₈	T ₉ (°C)
0	75	75	80	85	90	50	50	60	75
1	75.0	76.3	80.0	86.3	92.5	50.0	52.5	57.5	72.5
2	75.7	76.9	80.0	86.3	93.2	51.3	52.2	57.5	71.9
3	76.3	77.0	80.2	86.3	93.2	51.3	52.7	57.3	71.9
4	76.3	77.3	80.2	86.3	93.2	51.7	52.7	57.5	71.8
5	76.6	77.3	80.3	86.3	93.2	51.7	52.9	57.4	71.9
6	76.6	77.5	80.3	86.4	93.2	51.9	52.9	57.5	71.9

Note that by the sixth iteration the change is less than 0.3°C; hence, we assume the temperature distribution is approximated by the last row of the table.

The heat rate per unit length can be determined by evaluating the heat rates in the x-direction for the control volumes about nodes 6, 7, and 8. From the schematic, find that

$$q' = q'_1 + q'_2 + q'_3$$

$$q' = k\Delta y \frac{T_8 - 25}{\Delta x} + k\Delta y \frac{T_7 - 25}{\Delta x} + k \frac{\Delta y}{2} \frac{T_6 - 25}{\Delta x}$$

Recognizing that $\Delta x = \Delta y$ and substituting numerical values, find

$$q' = 20 \frac{\text{W}}{\text{m} \cdot \text{K}} \left[(57.5 - 25) + (52.9 - 25) + \frac{1}{2}(51.9 - 25) \right] \text{K}$$

$$q' = 1477 \text{ W/m.}$$

<

COMMENTS: (1) Recognize that, while the temperature distribution may have been determined to a reasonable approximation, the uncertainty in the heat rate could be substantial. This follows since the heat rate is based upon a gradient and hence on temperature differences.

(2) Note that the initial guesses ($k = 0$) for the iteration are within 5°C of the final distribution. The geometry is simple enough that the guess can be very close. In some instances, a flux plot may be helpful and save labor in the calculation.

(3) In writing the FDEs, the iteration index (superscript k) was not included to simplify expression of the equations. However, the most recent value of $T_{m,n}$ is always used in the computations. Note that this system of FDEs is diagonally dominant and no rearrangement is required.

PROBLEM 4.62

KNOWN: Edge of adjoining walls ($k = 1 \text{ W/m}\cdot\text{K}$) represented by symmetrical element bounded by the diagonal symmetry adiabat and a section of the wall thickness over which the temperature distribution is assumed to be linear.

FIND: (a) Temperature distribution, heat rate and shape factor for the edge using the nodal network with $\Delta x = \Delta y = 10 \text{ mm}$; compare shape factor result with that from Table 4.1; (b) Assess the validity of assuming linear temperature distributions across sections at various distances from the edge.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties, and (3) Linear temperature distribution at specified locations across the section.

ANALYSIS: (a) Taking advantage of symmetry along the adiabat diagonal, all the nodes may be treated as interior nodes. Across the left-hand boundary, the temperature distribution is specified as linear. The finite-difference equations required to determine the temperature distribution, and hence the heat rate, can be written by inspection.

$$T_3 = 0.25(T_2 + T_4 + T_6 + T_c)$$

$$T_4 = 0.25(T_2 + T_5 + T_7 + T_3)$$

$$T_5 = 0.25(T_2 + T_2 + T_4 + T_4)$$

$$T_6 = 0.25(T_3 + T_7 + T_8 + T_b)$$

$$T_7 = 0.25(T_4 + T_4 + T_6 + T_6)$$

$$T_8 = 0.25(T_6 + T_6 + T_a + T_a)$$

The heat rate for both surfaces of the edge is

$$q'_{\text{tot}} = 2[q'_a + q'_b + q'_c + q'_d]$$

$$q'_{\text{tot}} = 2[k(\Delta x/2)(T_c - T_2)/\Delta y + k\Delta x(T_3 - T_2)/\Delta y + k\Delta x(T_4 - T_2)/\Delta y + k\Delta x(T_5 - T_2)/\Delta x]$$

The shape factor for the full edge is defined as

$$q'_{\text{tot}} = kS'(T_1 - T_2)$$

Solving the above equation set in IHT, the temperature ($^{\circ}\text{C}$) distribution is

Continued...

PROBLEM 4.62 (Cont.)

0 0 0 0 0
 25 18.75 12.5 6.25
 50 37.5 25.0
 75 56.25
 100

<

and the heat rate and shape factor are

$$q'_{\text{tot}} = 100 \text{ W/m} \quad S = 1$$

<

From Table 4.1, the edge shape factor is 0.54, considerably below our estimate from this coarse grid analysis.

(b) The effect of the linear temperature distribution on the shape factor estimate can be explored using a more extensive grid as shown below. The FDE analysis was performed with the linear distribution imposed as the different sections a, b, c, d, e. Following the same approach as above, find

<i>Location of linear distribution</i>	(a)	(b)	(c)	(d)	(e)
<i>Shape factor, S</i>	0.797	0.799	0.809	0.857	1.00

The shape factor estimate decreases as the imposed linear temperature distribution section is located further from the edge. We conclude that assuming the temperature distribution across the section directly at the edge is a poor-one.

COMMENTS: The grid spacing for this analysis is quite coarse making the estimates in poor agreement with the Table 4.1 result. However, the analysis does show the effect of positioning the linear temperature distribution condition.

PROBLEM 4.64

KNOWN: Straight fin of uniform cross section with prescribed thermal conditions and geometry; tip condition allows for convection.

FIND: (a) Calculate the fin heat rate, q'_f , and tip temperature, T_L , assuming one-dimensional heat transfer in the fin; calculate the Biot number to determine whether the one-dimensional assumption is valid, (b) Using the finite-element software FEHT, perform a two-dimensional analysis to determine the fin heat rate and the tip temperature; display the isotherms; describe the temperature field and the heat flow pattern inferred from the display, and (c) Validate your FEHT code against the 1-D analytical solution for a fin using a thermal conductivity of 50 and 500 W/m·K.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conduction with constant properties, (2) Negligible radiation exchange, (3) Uniform convection coefficient.

ANALYSIS: (a) Assuming one-dimensional conduction, q'_L and T_L can be determined using Eqs. 3.72 and 3.70, respectively, from Table 3.4, Case A. Alternatively, use the IHT *Model / Extended Surfaces / Temperature Distribution and Heat Rate / Straight Fin / Rectangular*. These results are tabulated below and labeled as “1-D.” The Biot number for the fin is

$$Bi = \frac{h(t/2)}{k} = \frac{500 \text{ W/m}^2 \cdot \text{K} (0.020 \text{ m}/2)}{5 \text{ W/m} \cdot \text{K}} = 1$$

(b, c) The fin can be drawn as a two-dimensional outline in FEHT with convection boundary conditions on the exposed surfaces, and with a uniform temperature on the base. Using a fine mesh (at least 1280 elements), solve for the temperature distribution and use the *View / Temperature Contours* command to view the isotherms and the *Heat Flow* command to determine the heat rate into the fin base. The results of the analysis are summarized in the table below.

k (W/m·K)	Bi	Tip temperature, T_L (°C)		Fin heat rate, q'_f (W/m)		Difference* (%)
		1-D	2-D	1-D	2-D	
5	1	100	100	1010	805	20
50	0.1	100.3	100	3194	2990	6.4
500	0.01	123.8	124	9812	9563	2.5

* Difference = $(q'_{f,1D} - q'_{f,2D}) \times 100 / q'_{f,1D}$

COMMENTS: (1) From part (a), since $Bi = 1 > 0.1$, the internal conduction resistance is not negligible. Therefore significant transverse temperature gradients exist, and the one-dimensional conduction assumption in the fin is a poor one.

Continued

PROBLEM 4.64 (Cont.)

(2) From the table, with $k = 5 \text{ W/m}\cdot\text{K}$ ($Bi = 1$), the 2-D fin heat rate obtained from the FEA analysis is 20% lower than that for the 1-D analytical analysis. This is as expected since the 2-D model accounts for transverse thermal resistance to heat flow. Note, however, that analyses predict the same tip temperature, a consequence of the fin approximating an infinitely long fin ($mL = 20.2 \gg 2.56$; see Ex. 3.8 Comments).

(3) For the $k = 5 \text{ W/m}\cdot\text{K}$ case, the FEHT isotherms show considerable curvature in the region near the fin base. For example, at $x = 10$ and 20 mm , the difference between the centerline and surface temperatures are 15 and 7°C .

(4) From the table, with increasing thermal conductivity, note that Bi decreases, and the one-dimensional heat transfer assumption becomes more appropriate. The difference for the case when $k = 500 \text{ W/m}\cdot\text{K}$ is mostly due to the approximate manner in which the heat rate is calculated in the FEA software.

PROBLEM 4.65

KNOWN: Long rectangular bar having one boundary exposed to a convection process (T_∞ , h) while the other boundaries are maintained at constant temperature T_s .

FIND: Using the finite-element method of FEHT, (a) Determine the temperature distribution, plot the isotherms, and identify significant features of the distribution, (b) Calculate the heat rate per unit length (W/m) into the bar from the air stream, and (c) Explore the effect on the heat rate of increasing the convection coefficient by factors of two and three; explain why the change in the heat rate is not proportional to the change in the convection coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) The symmetrical section shown in the schematic is drawn in FEHT with the specified boundary conditions and material property. The *View | Temperature Contours* command is used to represent ten isotherms (isopotentials) that have minimum and maximum values of 53.9°C and 85.9°C, respectively.

Because of the symmetry boundary condition, the isotherms are normal to the center-plane indicating an adiabatic surface. Note that the temperature change along the upper surface of the bar is substantial ($\approx 40^\circ\text{C}$), whereas the lower half of the bar has less than a 3°C change. That is, the lower half of the bar is largely unaffected by the heat transfer conditions at the upper surface.

(b, c) Using the *View | Heat Flows* command considering the upper surface boundary with selected convection coefficients, the heat rates into the bar from the air stream were calculated.

$h \text{ (W/m}^2 \cdot \text{K)}$	100	200	300
$q' \text{ (W/m)}$	128	175	206

Increasing the convection coefficient by factors of 2 and 3, increases the heat rate by 37% and 61%, respectively. The heat rate from the bar to the air stream is controlled by the thermal resistances of the bar (conduction) and the convection process. Since the conduction resistance is significant, we should not expect the heat rate to change proportionally to the change in convection resistance.

PROBLEM 4.66

KNOWN: Log rod of rectangular cross-section of Problem 4.53 that experiences uniform heat generation while its surfaces are maintained at a fixed temperature. Use the finite-element software FEHT as your analysis tool.

FIND: (a) Represent the temperature distribution with representative isotherms; identify significant features; and (b) Determine what heat generation rate will cause the midpoint to reach 600 K with unchanged boundary conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, and (2) Two-dimensional conduction with constant properties.

ANALYSIS: (a) Using *FEHT*, do the following: in *Setup*, enter an appropriate scale; *Draw* the outline of the symmetrical section shown in the above schematic; *Specify* the *Boundary Conditions* (zero heat flux or adiabatic along the symmetrical lines, and isothermal on the edges). Also *Specify* the *Material Properties* and *Generation* rate. *Draw* three *Element Lines* as shown on the annotated version of the *FEHT* screen below. To reduce the mesh, hit *Draw/Reduce Mesh* until the desired fineness is achieved (256 elements is a good choice).

Continued ...

PROBLEM 4.66 (Cont.)

After hitting *Run*, *Check* and then *Calculate*, use the *View/Temperature Contours* and select the 10-isopotential option to display the isotherms as shown in an annotated copy of the *FEHT* screen below.

The isotherms are normal to the symmetrical lines as expected since those surfaces are adiabatic. The isotherms, especially near the center, have an elliptical shape. Along the $x = 0$ axis and the $y = 10$ mm axis, the temperature gradient is nearly linear. The hottest point is of course the center for which the temperature is

$$T(0, 10 \text{ mm}) = 401.3 \text{ K.}$$

<

The temperature of this point can be read using the *View/Temperatures* or *View/Tabular Output* command.

(b) To determine the required generation rate so that $T(0, 10 \text{ mm}) = 600 \text{ K}$, it is necessary to re-run the model with several guessed values of \dot{q} . After a few trials, find

$$\dot{q} = 1.48 \times 10^8 \text{ W/m}^3$$

<

PROBLEM 4.67

KNOWN: Symmetrical section of a flow channel with prescribed values of \dot{q} and k , as well as the surface convection conditions. See Problem 4.46.

FIND: Using the finite-element method of FEHT, (a) Determine the temperature distribution and plot the isotherms; identify the coolest and hottest regions, and the region with steepest gradients; describe the heat flow field, (b) Calculate the heat rate per unit length (W/m) from the outer surface A to the adjacent fluid, (c) Calculate the heat rate per unit length (W/m) to surface B from the inner fluid, and (d) Verify that the results are consistent with an overall energy balance on the section.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) The symmetrical section shown in the schematic is drawn in FEHT with the specified boundary conditions, material property and generation. The *View | Temperature Contours* command is used to represent ten isotherms (isopotentials) that have minimum and maximum values of 82.1°C and 125.2°C.

The hottest region of the section is the upper vertical leg (left-hand corner). The coolest region is in the lower horizontal leg at the far right-hand boundary. The maximum and minimum section temperatures (125°C and 77°C), respectively, are higher than either adjoining fluid. Remembering that heat flow lines are normal to the isotherms, heat flows from the hottest corner directly to the inner fluid and downward into the lower leg and then flows out surface A and the lower portion of surface B.

Continued

PROBLEM 4.67 (Cont.)

(b, c) Using the *View | Heat Flows* command considering the boundaries for surfaces A and B, the heat rates are:

$$q'_s = 1135 \text{ W/m}$$

$$q'_B = -1365 \text{ W/m.}$$

<

From an energy balance on the section, we note that the results are consistent since conservation of energy is satisfied.

$$\dot{E}'_{\text{in}} - \dot{E}'_{\text{out}} + \dot{E}_g = 0$$

$$-q'_A + q'_B + \dot{q}\nabla' = 0$$

$$-1135 \text{ W/m} + (-1365 \text{ W/m}) + 2500 \text{ W/m} = 0$$

<

where $\dot{q}\nabla' = 1 \times 10^6 \text{ W/m}^3 \times [25 \times 50 + 25 \times 50] \times 10^{-6} \text{ m}^2 = 2500 \text{ W/m}$.

COMMENTS: (1) For background on setting up this problem in FEHT, see the tutorial example of the User's Manual. While the boundary conditions are different, and the internal generation term is to be included, the procedure for performing the analysis is the same.

(2) The heat flow distribution can be visualized using the *View | Temperature Gradients* command. The direction and magnitude of the heat flow is represented by the directions and lengths of arrows. Compare the heat flow distribution to the isotherms shown above.

PROBLEM 4.68

KNOWN: Hot-film flux gage for determining the convection coefficient of an adjoining fluid stream by measuring the dissipated electric power, P_e , and the average surface temperature, $T_{s,f}$.

FIND: Using the finite-element method of *FEHT*, determine the fraction of the power dissipation that is conducted into the quartz substrate considering three cases corresponding to convection coefficients of 500, 1000 and 2000 $\text{W/m}^2\cdot\text{K}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant substrate properties, (3) Uniform convection coefficient over the hot-film and substrate surfaces, (4) Uniform power dissipation over hot film.

ANALYSIS: The symmetrical section shown in the schematic above (right) is drawn into *FEHT* specifying the substrate material property. On the upper surface, a convection boundary condition

(T_{∞}, h) is specified over the full width $W/2$. Additionally, an applied uniform flux $(P_e'', W/m^2)$

boundary condition is specified for the hot-film region ($w/2$). The remaining surfaces of the two-dimensional system are specified as adiabatic. In the schematic below, the electrical power dissipation P_e' (W/m) in the hot film is transferred by convection from the film surface, $q'_{cv,f}$, and from the adjacent substrate surface, $q'_{cv,s}$.

The analysis evaluates the fraction, F , of the dissipated electrical power that is conducted into the substrate and convected to the fluid stream,

$$F = q'_{cv,s} / P_e' = 1 - q'_{cv,f} / P_e'$$

where $P_e' = P_e'' (w/2) = 5000 \text{ W/m}^2 \times (0.002 \text{ m}) = 10 \text{ W/m}$.

After solving for the temperature distribution, the *View/Heat Flow* command is used to evaluate $q'_{cv,f}$ for the three values of the convection coefficient.

PROBLEM 4.68 (Cont.)

Case	$h(\text{W/m}^2 \cdot \text{K})$	$q'_{\text{cv},f} (\text{W/m})$	$F(\%)$	$T_{s,f} (^\circ\text{C})$
1	500	5.64	43.6	30.9
2	1000	6.74	32.6	28.6
3	2000	7.70	23.3	27.0

COMMENTS: (1) For the ideal hot-film flux gage, there is negligible heat transfer to the substrate, and the convection coefficient of the air stream is calculated from the measured electrical power, P_e'' , the average film temperature (by a thin-film thermocouple), $T_{s,f}$, and the fluid stream temperature, T_∞ , as $h = P_e'' / (T_{s,f} - T_\infty)$. The purpose in performing the present analysis is to estimate a correction factor to account for heat transfer to the substrate.

(2) As anticipated, the fraction of the dissipated electrical power conducted into the substrate, F , decreases with increasing convection coefficient. For the case of the largest convection coefficient, F amounts to 25%, making it necessary to develop a reliable, accurate heat transfer model to estimate the applied correction. Further, this condition limits the usefulness of this gage design to flows with high convection coefficients.

(3) A reduction in F , and hence the effect of an applied correction, could be achieved with a substrate material having a lower thermal conductivity than quartz. However, quartz is a common substrate material for fabrication of thin-film heat-flux gages and thermocouples. By what other means could you reduce F ?

(4) In addition to the tutorial example in the *FEHT* User's Manual, the solved models for Examples 4.3 and 4.4 are useful for developing skills helpful in solving this problem.

PROBLEM 4.69

KNOWN: Hot-plate tool for micro-lithography processing of 300-mm silicon wafer consisting of an aluminum alloy equalizing block (EB) heated by ring-shaped main and trim electrical heaters (MH and TH) providing two-zone control.

FIND: The assignment is to size the heaters, MH and TH, by specifying their applied heat fluxes, q''_{mh} and q''_{th} , and their radial extents, Δr_{mh} and Δr_{th} , to maintain an operating temperature of 140°C with a uniformity of 0.1°C . Consider these steps in the analysis: (a) Perform an energy balance on the EB to obtain an initial estimate for the heater fluxes with $q''_{mh} = q''_{th}$ extending over the full radial limits; using *FEHT*, determine the upper surface temperature distribution and comment on whether the desired uniformity has been achieved; (b) Re-run your *FEHT* code with different values of the heater fluxes to obtain the best uniformity possible and plot the surface temperature distribution; (c) Re-run your *FEHT* code for the best arrangement found in part (b) using the representative distribution of the convection coefficient (see schematic for $h(r)$ for downward flowing gas across the upper surface of the EB; adjust the heat flux of TH to obtain improved uniformity; and (d) Suggest changes to the design for improving temperature uniformity.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction with uniform and constant properties in EB, (3) Lower surface of EB perfectly insulated, (4) Uniform convection coefficient over upper EB surface, unless otherwise specified and (5) negligible radiation exchange between the EB surfaces and the surroundings.

ANALYSIS: (a) To obtain initial estimates for the MH and TH fluxes, perform an overall energy balance on the EB as illustrated in the schematic below.

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q''_{mh}\pi(r_2^2 - r_1^2) + q''_{th}\pi(r_4^2 - r_3^2) - h\left[\pi r_o^2 + 2\pi r_o w\right](T_s - T_\infty) = 0$$

Continued

PROBLEM 4.69 (Cont.)

Substituting numerical values and letting $q''_{mh} = q''_{th}$, find

$$q''_{mh} = q''_{th} = 2939 \text{ W/m}^2$$

<

Using *FEHT*, the analysis is performed on an axisymmetric section of the EB with the nodal arrangement as shown below.

The *Temperature Contour* view command is used to create the temperature distribution shown below. The temperatures at the center (T_1) and the outer edge of the wafer ($r = 150 \text{ mm}$, T_{14}) are read from the *Tabular Output* page. The *Temperature Gradients* view command is used to obtain the heat flow distribution when the line length is proportional to the magnitude of the heat rate.

From the analysis results, for this base case design ($q''_{mh} = q''_{th}$), the temperature difference across the radius of the wafer is 1.7°C , much larger than the design goal of 0.1°C . The upper surface temperature distribution is shown in the graph below.

Continued

PROBLEM 4.69 (Cont.)

(b) From examination of the results above, we conclude that if q''_{mh} is reduced and q''_{th} increased, the EB surface temperature uniformity could improve. The results of three trials compared to the base case are tabulated below.

Trial	q''_{mh} (W / m ²)	q''_{th} (W / m ²)	T ₁ (°C)	T ₁₄ (°C)	T ₁ - T ₁₄ (°C)
Base	2939	2939	141.1	139.3	1.8
1	2880 (-2%)	2997 (+2%)	141.1	139.4	1.7
2	2880 (-2%)	3027 (+3%)	141.7	140.0	1.7
3	2910 (-1%)	2997 (+2%)	141.7	139.9	1.8
Part (c)	2939	2939	141.7	139.1	2.6
Part (d) k=150 W/m·K	2939	2939	140.4	139.5	0.9
Part (d) k=300 W/m·K	2939	2939	140.0	139.6	0.4

The strategy of changing the heater fluxes (trials 1-3) has not resulted in significant improvements in the EB surface temperature uniformity.

Continued

PROBLEM 4.69 (Cont.)

(c) Using the same *FEHT* code as with part (b), base case, the boundary conditions on the upper surface of the EB were specified by the function $h(r)$ shown in the schematic. The value of $h(r)$ ranged from 5.4 to 13.5 W/m²·K between the centerline and EB edge. The result of the analysis is tabulated above, labeled as part (c). Note that the temperature uniformity has become significantly poorer.

(d) There are at least two options that should be considered in the re-design to improve temperature uniformity. *Higher thermal conductivity material for the EB.* Aluminum alloy is the material most widely used in practice for reasons of low cost, ease of machining, and durability of the heated surface. The results of analyses for thermal conductivity values of 150 and 300 W/m·K are tabulated above, labeled as part (d). Using pure or oxygen-free copper could improve the temperature uniformity to better than 0.5°C.

Distributed heater elements. The initial option might be to determine whether temperature uniformity could be improved using two elements, but located differently. Another option is a single element heater spirally embedded in the lower portion of the EB. By appropriately positioning the element as a function of the EB radius, improved uniformity can be achieved. This practice is widely used where precise and uniform temperature control is needed.

PROBLEM 4.70

KNOWN: Straight fin of uniform cross section with insulated end.

FIND: (a) Temperature distribution using finite-difference method and validity of assuming one-dimensional heat transfer, (b) Fin heat transfer rate and comparison with analytical solution, Eq. 3.76, (c) Effect of convection coefficient on fin temperature distribution and heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fin, (3) Constant properties, (4) Uniform film coefficient.

ANALYSIS: (a) From the analysis of Problem 4.43, the finite-difference equations for the nodal arrangement can be directly written. For the nodal spacing $\Delta x = 4$ mm, there will be 12 nodes. With $\ell \gg w$ representing the distance normal to the page,

$$\frac{hP}{kA_c} \cdot \Delta x^2 \approx \frac{h \cdot 2\ell}{k \cdot \ell \cdot w} \Delta x^2 = \frac{h \cdot 2}{kw} \Delta x^2 = \frac{500 \text{ W/m}^2 \cdot \text{K} \times 2}{50 \text{ W/m} \cdot \text{K} \times 6 \times 10^{-3} \text{ m}} (4 \times 10^{-3} \text{ m}) = 0.0533$$

$$\text{Node 1: } 100 + T_2 + 0.0533 \times 30 - (2 + 0.0533)T_1 = 0 \quad \text{or} \quad -2.053T_1 + T_2 = -101.6$$

$$\text{Node } n: \quad T_{n+1} + T_{n-1} + 1.60 - 2.053T_n = 0 \quad \text{or} \quad T_{n-1} - 2.053T_n + T_{n+1} = -1.60$$

$$\text{Node 12: } T_{11} + (0.0533/2)30 - (0.0533/2 + 1)T_{12} = 0 \quad \text{or} \quad T_{11} - 1.0267T_{12} = -0.800$$

Using matrix notation, Eq. 4.48, where $[A][T] = [C]$, the A-matrix is tridiagonal and only the non-zero terms are shown below. A matrix inversion routine was used to obtain $[T]$.

Tridiagonal Matrix A

Nonzero Terms				Values	
	$a_{1,1}$	$a_{1,2}$		-2.053	1

10	-1.6	39.9
11	-1.6	39.2
12	-0.8	38.9

The assumption of one-dimensional heat conduction is justified when $Bi \equiv h(w/2)/k < 0.1$. Hence, with $Bi = 500 \text{ W/m}^2 \cdot \text{K}(3 \times 10^{-3} \text{ m})/50 \text{ W/m} \cdot \text{K} = 0.03$, the assumption is reasonable.

Continued...

PROBLEM 4.70 (Cont.)

(b) The fin heat rate can be most easily found from an energy balance on the control volume about Node 0,

$$q'_f = q'_1 + q'_{\text{conv}} = k \cdot w \frac{T_0 - T_1}{\Delta x} + h \left(2 \frac{\Delta x}{2} \right) (T_0 - T_\infty)$$

$$q'_f = 50 \text{ W/m} \cdot \text{K} \left(6 \times 10^{-3} \text{ m} \right) \frac{(100 - 85.8)^\circ \text{C}}{4 \times 10^{-3} \text{ m}} + 500 \text{ W/m}^2 \cdot \text{K} \left(2 \cdot \frac{4 \times 10^{-3} \text{ m}}{2} \right) (100 - 30)^\circ \text{C}$$

$$q'_f = (1065 + 140) \text{ W/m} = 1205 \text{ W/m}.$$

<

From Eq. 3.76, the fin heat rate is

$$q = (hPkA_c)^{1/2} \cdot \theta_b \cdot \tanh mL.$$

Substituting numerical values with $P = 2(w + \ell) \approx 2\ell$ and $A_c = w \cdot \ell$, $m = (hP/kA_c)^{1/2} = 57.74 \text{ m}^{-1}$ and $M = (hPkA_c)^{1/2} = 17.32 \ell \text{ W/K}$. Hence, with $\theta_b = 70^\circ \text{C}$,

$$q' = 17.32 \text{ W/K} \times 70 \text{ K} \times \tanh(57.44 \times 0.048) = 1203 \text{ W/m}$$

and the finite-difference result agrees very well with the exact (analytical) solution.

(c) Using the IHT *Finite-Difference Equations Tool Pad* for 1D, SS conditions, the fin temperature distribution and heat rate were computed for $h = 10, 100, 500$ and $1000 \text{ W/m}^2 \cdot \text{K}$. Results are plotted as follows.

The temperature distributions were obtained by first creating a *Lookup Table* consisting of 4 rows of nodal temperatures corresponding to the 4 values of h and then using the *LOOKUPVAL2* interpolating function with the *Explore* feature of the IHT menu. Specifically, the function $T_EVAL = \text{LOOKUPVAL2}(t0467, h, x)$ was entered into the workspace, where $t0467$ is the file name given to the Lookup Table. For each value of h , *Explore* was used to compute $T(x)$, thereby generating 4 data sets which were placed in the *Browser* and used to generate the plots. The variation of q' with h was simply generated by using the *Explore* feature to solve the finite-difference model equations for values of h incremented by 10 from 10 to $1000 \text{ W/m}^2 \cdot \text{K}$.

Although q'_f increases with increasing h , the effect of changes in h becomes less pronounced. This trend is a consequence of the reduction in fin temperatures, and hence the fin efficiency, with increasing h . For $10 \leq h \leq 1000 \text{ W/m}^2 \cdot \text{K}$, $0.95 \geq \eta_f \geq 0.24$. Note the nearly isothermal fin for $h = 10 \text{ W/m}^2 \cdot \text{K}$ and the pronounced temperature decay for $h = 1000 \text{ W/m}^2 \cdot \text{K}$.

PROBLEM 4.71

KNOWN: Pin fin of 10 mm diameter and length 250 mm with base temperature of 100°C experiencing radiation exchange with the surroundings and free convection with ambient air.

FIND: Temperature distribution using finite-difference method with five nodes. Fin heat rate and relative contributions by convection and radiation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fin, (3) Constant properties, (4) Fin approximates small object in large enclosure, (5) Fin tip experiences convection and radiation, (6) $h_{fc} = 2.89[0.6 + 0.624(T - T_\infty)^{1/6}]^2$.

ANALYSIS: To apply the finite-difference method, define the 5-node system shown above where $\Delta x = L/5$. Perform energy balances on the nodes to obtain the finite-difference equations for the nodal temperatures.

Interior node, $n = 1, 2, 3$ or 4

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_a + q_b + q_c + q_d = 0 \quad (1)$$

$$h_{r,n} P \Delta x (T_{sur} - T_n) + k A_c \frac{T_{n+1} - T_n}{\Delta x} + h_{fc,n} P \Delta x (T_\infty - T_n) + k A_c \frac{T_{n-1} - T_n}{\Delta x} = 0 \quad (2)$$

where the free convection coefficient is

$$h_{fc,n} = 2.89 \left[0.6 + 0.624 (T_n - T_\infty)^{1/6} \right]^2 \quad (3)$$

and the linearized radiation coefficient is

$$h_{r,n} = \epsilon \sigma (T_n + T_{sur}) (T_n^2 + T_{sur}^2) \quad (4)$$

with $P = \pi D$ and $A_c = \pi D^2/4$.

(5,6)

Tip node, $n = 5$

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_a + q_b + q_c + q_d + q_e = 0$$

$$h_{r,5} (P \Delta x / 2) (T_{sur} - T_5) + h_{r,5} A_c (T_{sur} - T_5) + h_{fc,5} A_c (T_\infty - T_5) + h_{fc,5} (P \Delta x / 2) (T_\infty - T_5) + k A_c \frac{T_4 - T_5}{\Delta x} = 0 \quad (7)$$

Continued...

PROBLEM 4.71 (Cont.)

Knowing the nodal temperatures, the heat rates are evaluated as:

Fin Heat Rate: Perform an energy balance around Node b.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$q_a + q_b + q_c + q_{\text{fin}} = 0$$

$$h_{r,b} (P\Delta x/2)(T_{\text{sur}} - T_b) + h_{fc,b} (P\Delta x/2)(T_{\infty} - T_b) + kA_c \frac{(T_1 - T_b)}{\Delta x} + q_{\text{fin}} = 0 \quad (8)$$

where $h_{r,b}$ and $h_{fc,b}$ are evaluated at T_b .

Convection Heat Rate: To determine the portion of the heat rate by convection from the fin surface, we need to sum contributions from each node. Using the convection heat rate terms from the foregoing energy balances, for, respectively, node b, nodes 1, 2, 3, 4 and node 5.

$$q_{cv} = -q_b)_b - \sum q_c)_{1-4} - (q_c + q_d)_5 \quad (9)$$

Radiation Heat Rate: In the same manner,

$$q_{\text{rad}} = -q_a)_b - \sum q_b)_{1-4} - (q_a + q_b)_5$$

The above equations were entered into the IHT workspace and the set of equations solved for the nodal temperatures and the heat rates. Summary of key results including the temperature distribution and heat rates is shown below.

Node	b	1	2	3	4	5	Fin	<
T_j (°C)	100	58.5	40.9	33.1	29.8	28.8	-	
q_{cv} (W)	0.603	0.451	0.183	0.081	0.043	0.015	1.375	
q_{fin} (W)	-	-	-	-	-	-	1.604	
q_{rad} (W)	-	-	-	-	-	-	0.229	
h_{cv} (W/m ² ·K)	10.1	8.6	7.3	6.4	5.7	5.5	-	
h_{rad} (W/m ² ·K)	1.5	1.4	1.3	1.3	1.2	1.2	-	

COMMENTS: From the tabulated results, it is evident that free convection is the dominant mode. Note that the free convection coefficient varies almost by a factor of two over the length of the fin.

PROBLEM 4.72

KNOWN: Thin metallic foil of thickness, t , whose edges are thermally coupled to a sink at temperature T_{sink} is exposed on the top surface to an ion beam heat flux, q_s'' , and experiences radiation exchange with the vacuum enclosure walls at T_{sur} .

FIND: Temperature distribution across the foil.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction in the foil, (2) Constant properties, (3) Upper and lower surfaces of foil experience radiation exchange, (4) Foil is of unit length normal to the page.

ANALYSIS: The 10-node network representing the foil is shown below.

From an energy balance on node n , $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$, for a unit depth,

$$q'_a + q'_b + q'_c + q'_d + q'_e = 0$$

$$q_s'' \Delta x + h_{r,n} \Delta x (T_{\text{sur}} - T_n) + k(t)(T_{n+1} - T_n)/\Delta x + h_{r,n} \Delta x (T_{\text{sur}} - T_n) + k(t)(T_{n-1} - T_n)/\Delta x = 0 \quad (1)$$

where the linearized radiation coefficient for node n is

$$h_{r,n} = \varepsilon \sigma (T_{\text{sur}} + T_n) (T_{\text{sur}}^2 + T_n^2) \quad (2)$$

Solving Eq. (1) for T_n find,

$$T_n = \left[(T_{n+1} + T_{n-1}) + \left(2h_{r,n} \Delta x^2 / kt \right) T_{\text{sur}} + \left(\Delta x^2 / kt \right) q_s'' \right] / \left[\left(h_{r,n} \Delta x^2 / kt \right) + 2 \right] \quad (3)$$

which, considering symmetry, applies also to node 1. Using IHT for Eqs. (3) and (2), the set of finite-difference equations was solved for the temperature distribution (K):

T_1	T_2	T_3	T_4	T_5	T_6	T_7	T_8	T_9	T_{10}
374.1	374.0	373.5	372.5	370.9	368.2	363.7	356.6	345.3	327.4

Continued...

PROBLEM 4.72 (Cont.)

COMMENTS: (1) If the temperature gradients were excessive across the foil, it would wrinkle; most likely since its edges are constrained, the foil will bow.

(2) The IHT workspace for the finite-difference analysis follows:

// The nodal equations:

$$T1 = (T2 + T2) + A1 * Tsur + B * q''s / (A1 + 2)$$

$$A1 = 2 * hr1 * \text{deltax}^2 / (k * t)$$

$$hr1 = \text{eps} * \text{sigma} * (Tsur + T1) * (Tsur^2 + T1^2)$$

$$\text{sigma} = 5.67\text{e-}8$$

$$B = \text{deltax}^2 / (k * t)$$

$$T2 = (T1 + T3) + A2 * Tsur + B * q''s / (A2 + 2)$$

$$A2 = 2 * hr2 * \text{deltax}^2 / (k * t)$$

$$hr2 = \text{eps} * \text{sigma} * (Tsur + T2) * (Tsur^2 + T2^2)$$

$$T3 = (T2 + T4) + A3 * Tsur + B * q''s / (A3 + 2)$$

$$A3 = 2 * hr3 * \text{deltax}^2 / (k * t)$$

$$hr3 = \text{eps} * \text{sigma} * (Tsur + T3) * (Tsur^2 + T3^2)$$

$$T4 = (T3 + T5) + A4 * Tsur + B * q''s / (A4 + 2)$$

$$A4 = 2 * hr4 * \text{deltax}^2 / (k * t)$$

$$hr4 = \text{eps} * \text{sigma} * (Tsur + T4) * (Tsur^2 + T4^2)$$

$$T5 = (T4 + T6) + A5 * Tsur + B * q''s / (A5 + 2)$$

$$A5 = 2 * hr5 * \text{deltax}^2 / (k * t)$$

$$hr5 = \text{eps} * \text{sigma} * (Tsur + T5) * (Tsur^2 + T5^2)$$

$$T6 = (T5 + T7) + A6 * Tsur + B * q''s / (A6 + 2)$$

$$A6 = 2 * hr6 * \text{deltax}^2 / (k * t)$$

$$hr6 = \text{eps} * \text{sigma} * (Tsur + T6) * (Tsur^2 + T6^2)$$

$$T7 = (T6 + T8) + A7 * Tsur + B * q''s / (A7 + 2)$$

$$A7 = 2 * hr7 * \text{deltax}^2 / (k * t)$$

$$hr7 = \text{eps} * \text{sigma} * (Tsur + T7) * (Tsur^2 + T7^2)$$

$$T8 = (T7 + T9) + A8 * Tsur + B * q''s / (A8 + 2)$$

$$A8 = 2 * hr8 * \text{deltax}^2 / (k * t)$$

$$hr8 = \text{eps} * \text{sigma} * (Tsur + T8) * (Tsur^2 + T8^2)$$

$$T9 = (T8 + T10) + A9 * Tsur + B * q''s / (A9 + 2)$$

$$A9 = 2 * hr9 * \text{deltax}^2 / (k * t)$$

$$hr9 = \text{eps} * \text{sigma} * (Tsur + T9) * (Tsur^2 + T9^2)$$

$$T10 = (T9 + Tsink) + A10 * Tsur + B * q''s / (A10 + 2)$$

$$A10 = 2 * hr10 * \text{deltax}^2 / (k * t)$$

$$hr10 = \text{eps} * \text{sigma} * (Tsur + T10) * (Tsur^2 + T10^2)$$

PROBLEM 4.73

KNOWN: Electrical heating elements with known dissipation rate embedded in a ceramic plate of known thermal conductivity; lower surface is insulated, while upper surface is exposed to a convection process.

FIND: (a) Temperature distribution within the plate using prescribed grid spacing, (b) Sketch isotherms to illustrate temperature distribution, (c) Heat loss by convection from exposed surface (compare with element dissipation rate), (d) Advantage, if any, in not setting $\Delta x = \Delta y$, (e) Effect of grid size and convection coefficient on the temperature field.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction in ceramic plate, (2) Constant properties, (3) No internal generation, except for Node 7 (or Node 15 for part (e)), (4) Heating element approximates a line source of negligible wire diameter.

ANALYSIS: (a) The prescribed grid for the symmetry element shown above consists of 12 nodal points. Nodes 1-3 are points on a surface experiencing convection; nodes 4-6 and 8-12 are interior nodes. Node 7 is a special case of the interior node having a generation term; because of symmetry, $q'_{ht} = 25 \text{ W/m}$. The finite-difference equations are derived as follows:

Continued...

PROBLEM 4.73 (Cont.)

Surface Node 2. From an energy balance on the prescribed control volume with $\Delta x/\Delta y = 3$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = q'_a + q'_b + q'_c + q'_d = 0;$$

$$k \frac{\Delta y}{2} \frac{T_1 - T_2}{\Delta x} + h \Delta x (T_\infty - T_2) + k \frac{\Delta y}{2} \frac{T_3 - T_2}{\Delta x} + k \Delta x \frac{T_5 - T_2}{\Delta y} = 0.$$

Regrouping, find

$$T_2 \left[1 + 2N \frac{\Delta x}{\Delta y} + 1 + 2 \left(\frac{\Delta x}{\Delta y} \right)^2 \right] = T_1 + T_3 + 2 \left(\frac{\Delta x}{\Delta y} \right)^2 T_5 + 2N \frac{\Delta x}{\Delta y} T_\infty$$

where $N = h \Delta x / k = 100 \text{ W/m}^2 \cdot \text{K} \times 0.006 \text{ m} / 2 \text{ W/m} \cdot \text{K} = 0.30 \text{ K}$. Hence, with $T_\infty = 30^\circ\text{C}$,

$$T_2 = 0.04587T_1 + 0.04587T_3 + 0.82569T_5 + 2.4771 \quad (1)$$

From this FDE, the forms for nodes 1 and 3 can also be deduced.

Interior Node 7. From an energy balance on the prescribed control volume, with $\Delta x/\Delta y = 3$,

$\dot{E}'_{\text{in}} - \dot{E}'_{\text{g}} = 0$, where $\dot{E}'_{\text{g}} = 2q'_{\text{ht}}$ and \dot{E}'_{in} represents the conduction terms. Hence,

$$q'_a + q'_b + q'_c + q'_d + 2q'_{\text{ht}} = 0, \text{ or}$$

$$k \Delta y \frac{T_8 - T_7}{\Delta x} + k \Delta x \frac{T_4 - T_7}{\Delta y} + k \Delta y \frac{T_8 - T_7}{\Delta x} + k \Delta x \frac{T_{10} - T_7}{\Delta y} + 2q'_{\text{ht}} = 0$$

Regrouping,

$$T_7 \left[1 + \left(\frac{\Delta x}{\Delta y} \right)^2 + 1 + \left(\frac{\Delta x}{\Delta y} \right)^2 \right] = T_8 + \left(\frac{\Delta x}{\Delta y} \right)^2 T_4 + T_8 + \left(\frac{\Delta x}{\Delta y} \right)^2 T_{10} + \frac{2q'_{\text{ht}}}{k} \left(\frac{\Delta x}{\Delta y} \right)$$

Recognizing that $\Delta x/\Delta y = 3$, $q'_{\text{ht}} = 25 \text{ W/m}$ and $k = 2 \text{ W/m} \cdot \text{K}$, the FDE is

$$T_7 = 0.0500T_8 + 0.4500T_4 + 0.0500T_8 + 0.4500T_{10} + 3.7500 \quad (2)$$

The FDEs for the remaining nodes may be deduced from this form. Following the procedure described in Section 4.5.2 for the Gauss-Seidel method, the system of FDEs has the form:

$$\begin{aligned} T_1^k &= 0.09174T_2^{k-1} + 0.8257T_4^{k-1} + 2.4771 \\ T_2^k &= 0.04587T_1^k + 0.04587T_3^{k-1} + 0.8257T_5^{k-1} + 2.4771 \\ T_3^k &= 0.09174T_2^k + 0.8257T_6^{k-1} + 2.4771 \\ T_4^k &= 0.4500T_1^k + 0.1000T_5^{k-1} + 0.4500T_7^{k-1} \\ T_5^k &= 0.4500T_2^k + 0.0500T_4^k + 0.0500T_6^{k-1} + 0.4500T_8^{k-1} \\ T_6^k &= 0.4500T_3^k + 0.1000T_5^k + 0.4500T_9^{k-1} \\ T_7^k &= 0.4500T_4^k + 0.1000T_8^{k-1} + 0.4500T_{10}^{k-1} + 3.7500 \\ T_8^k &= 0.4500T_5^k + 0.0500T_7^k + 0.0500T_9^{k-1} + 0.4500T_{11}^{k-1} \\ T_9^k &= 0.4500T_6^k + 0.1000T_8^k + 0.4500T_{12}^{k-1} \\ T_{10}^k &= 0.9000T_7^k + 0.1000T_{11}^{k-1} \\ T_{11}^k &= 0.9000T_8^k + 0.0500T_{10}^{k-1} + 0.0500T_{12}^{k-1} \\ T_{12}^k &= 0.9000T_9^k + 0.1000T_{11}^k \end{aligned}$$

Continued

PROBLEM 4.73 (Cont.)

Note the use of the superscript k to denote the level of iteration. Begin the iteration procedure with rational estimates for T_i ($k = 0$) and prescribe the convergence criterion as $\varepsilon \leq 0.1$ K.

k/T_i	1	2	3	4	5	6	7	8	9	10	11	12
0	55.0	50.0	45.0	61.0	54.0	47.0	65.0	56.0	49.0	60.0	55.0	50.0
1	57.4	51.7	46.0	60.4	53.8	48.1	63.5	54.6	49.6	62.7	54.8	50.1
2	57.1	51.6	46.9	59.7	53.2	48.7	64.3	54.3	49.9	63.4	54.5	50.4
∞	55.80	49.93	47.67	59.03	51.72	49.19	63.89	52.98	50.14	62.84	53.35	50.46

The last row with $k = \infty$ corresponds to the solution obtained by matrix inversion. It appears that at least 20 iterations would be required to satisfy the convergence criterion using the Gauss-Seidel method.

(b) Selected isotherms are shown in the sketch of the nodal network.

Note that the isotherms are normal to the adiabatic surfaces.

(c) The heat loss by convection can be expressed as

$$q'_{\text{conv}} = h \left[\frac{1}{2} \Delta x (T_1 - T_{\infty}) + \Delta x (T_2 - T_{\infty}) + \frac{1}{2} \Delta x (T_3 - T_{\infty}) \right]$$

$$q'_{\text{conv}} = 100 \text{ W/m}^2 \cdot \text{K} \times 0.006 \text{ m} \left[\frac{1}{2} (55.80 - 30) + (49.93 - 30) + \frac{1}{2} (47.67 - 30) \right] = 25.00 \text{ W/m} \cdot \text{K} <$$

As expected, the heat loss by convection is equal to the heater element dissipation. This follows from the conservation of energy requirement.

(d) For this situation, choosing $\Delta x = 3\Delta y$ was advantageous from the standpoint of precision and effort. If we had chosen $\Delta x = \Delta y = 2$ mm, there would have been 28 nodes, doubling the amount of work, but with improved precision.

(e) Examining the effect of grid size by using the *Finite-Difference Equations* option from the *Tools* portion of the IHT Menu, the following temperature field was computed for $\Delta x = \Delta y = 2$ mm, where x and y are in mm and the temperatures are in $^{\circ}\text{C}$.

$y \backslash x$	0	2	4	6	8	10	12
0	55.04	53.88	52.03	50.32	49.02	48.24	47.97
2	58.71	56.61	54.17	52.14	50.67	49.80	49.51
4	66.56	59.70	55.90	53.39	51.73	50.77	50.46
6	63.14	59.71	56.33	53.80	52.09	51.11	50.78

Continued

PROBLEM 4.73 (Cont.)

Agreement with the results of part (a) is excellent, except in proximity to the heating element, where $T_{15} = 66.6^\circ\text{C}$ for the fine grid exceeds $T_7 = 63.9^\circ\text{C}$ for the coarse grid by 2.7°C .

For $h = 10 \text{ W/m}^2\cdot\text{K}$, the maximum temperature in the ceramic corresponds to $T_{15} = 254^\circ\text{C}$, and the heater could still be operated at the prescribed power. With $h = 10 \text{ W/m}^2\cdot\text{K}$, the critical temperature of $T_{15} = 400^\circ\text{C}$ would be reached with a heater power of approximately 82 W/m .

COMMENTS: (1) The method used to obtain the rational estimates for T_i ($k = 0$) in part (a) is as follows. Assume 25 W/m is transferred by convection uniformly over the surface; find $\bar{T}_{\text{surf}} \approx 50^\circ\text{C}$. Set $T_2 = 50^\circ\text{C}$ and recognize that T_1 and T_3 will be higher and lower, respectively. Assume 25 W/m is conducted uniformly to the outer nodes; find $T_5 - T_2 \approx 4^\circ\text{C}$. For the remaining nodes, use intuition to guess reasonable values. (2) In selecting grid size (and whether $\Delta x = \Delta y$), one should consider the region of largest temperature gradients. Predicted values of the maximum temperature in the ceramic will be very sensitive to the grid resolution.

NOTE TO INSTRUCTOR: Although the problem statement calls for calculations with $\Delta x = \Delta y = 1 \text{ mm}$, the instructional value and benefit-to-effort ratio are small. Hence, consideration of this grid size is not recommended.

PROBLEM 4.74

KNOWN: Silicon chip mounted in a dielectric substrate. One surface of system is convectively cooled while the remaining surfaces are well insulated.

FIND: Whether maximum temperature in chip will exceed 85°C .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Negligible contact resistance between chip and substrate, (4) Upper surface experiences uniform convection coefficient, (5) Other surfaces are perfectly insulated.

ANALYSIS: Performing an energy balance on the chip assuming it is *perfectly insulated* from the substrate, the maximum temperature occurring at the interface with the dielectric substrate will be, according to Eqs. 3.43 and 3.46,

$$T_{\max} = \frac{\dot{q}(H/4)^2}{2k_c} + \frac{\dot{q}(H/4)}{h} + T_\infty = \frac{10^7 \text{ W/m}^3 (0.003 \text{ m})^2}{2 \times 50 \text{ W/m} \cdot \text{K}} + \frac{10^7 \text{ W/m}^3 (0.003 \text{ m})}{500 \text{ W/m}^2 \cdot \text{K}} + 20^\circ\text{C} = 80.9^\circ\text{C}.$$

Since $T_{\max} < 85^\circ\text{C}$ for the assumed situation, for the actual two-dimensional situation with the conducting dielectric substrate, the maximum temperature should be less than 80°C .

Using the suggested grid spacing of 3 mm, construct the nodal network and write the finite-difference equation for each of the nodes taking advantage of symmetry of the system. Note that we have chosen to *not* locate nodes on the system surfaces for two reasons: (1) fewer total number of nodes, 20 vs. 25, and (2) Node 5 corresponds to center of chip which is likely the point of maximum temperature. Using these numerical values,

$$\begin{aligned} \frac{h\Delta x}{k_s} &= \frac{500 \text{ W/m}^2 \cdot \text{K} \times 0.003 \text{ m}}{5 \text{ W/m} \cdot \text{K}} = 0.30 & \alpha &= \frac{2}{(k_s/k_c) + 1} = \frac{2}{5/50 + 1} = 1.818 \\ \frac{h\Delta x}{k_c} &= \frac{500 \text{ W/m}^2 \cdot \text{K} \times 0.003 \text{ m}}{5 \text{ W/m} \cdot \text{K}} = 0.030 & \beta &= \frac{2}{(k_c/k_s) + 1} = \frac{2}{50/5 + 1} = 0.182 \\ \frac{\dot{q}\Delta x\Delta y}{k_c} &= 1.800 & \gamma &= \frac{1}{k_c/k_s + 1} = 0.0910 \end{aligned}$$

find the nodal equations:

$$\text{Node 1} \quad k_s \Delta x \frac{T_6 - T_1}{\Delta y} + k_s \Delta y \frac{T_2 - T_1}{\Delta x} + h \Delta x (T_\infty - T_1) = 0$$

Continued

PROBLEM 4.74 (Cont.)

$$-\left(2 + \frac{h\Delta x}{k_s}\right)T_1 + T_2 + T_6 = -\frac{h\Delta x}{k_s}T_\infty \quad -2.30T_1 + T_2 + T_6 = -6.00 \quad (1)$$

Node 2 $T_1 - 3.3T_2 + T_3 + T_7 = -6.00 \quad (2)$

Node 3

$$k_s\Delta y \frac{T_2 - T_3}{\Delta x} + \frac{T_4 - T_3}{(\Delta x/2)/k_c\Delta y + (\Delta x/2)/k_s\Delta y} + k_s\Delta x \frac{T_8 - T_3}{\Delta y} + h\Delta x(T_\infty - T_3) = 0$$

$$T_2 - (2 + \alpha + (h\Delta x/k_s)T_3) + \alpha T_4 + T_8 = -(h\Delta x/k)T_\infty$$

$$T_2 - 4.12T_3 + 1.82T_4 + T_8 = -6.00 \quad (3)$$

Node 4

$$\frac{T_3 - T_4}{(\Delta x/2)/k_s\Delta y + (\Delta x/2)/k_c\Delta y} + k_c\Delta y \frac{T_5 - T_4}{\Delta x} + \frac{T_9 - T_4}{(\Delta y/2)/k_s\Delta x + (\Delta y/2)k_c\Delta x} + \dot{q}(\Delta x\Delta y) + h\Delta x(T_\infty - T_4) = 0$$

$$\beta T_3 - (1 + 2\beta + [h\Delta x/k_c])T_4 + T_5 + \beta T_9 = -(h\Delta x/k_c)T_\infty - \dot{q}\Delta x\Delta y/k_c$$

$$0.182T_3 - 1.39T_4 + T_5 + 0.182T_9 = -2.40 \quad (4)$$

Node 5

$$k_c\Delta y \frac{T_4 - T_5}{\Delta x} + \frac{T_{10} - T_5}{(\Delta y/2)/k_s(\Delta x/2) + (\Delta y/2)/k_c(\Delta x/2)} + h(\Delta x/2)(T_\infty - T_5) + \dot{q}\Delta y(\Delta x/2) = 0$$

$$2T_4 - 2.21T_5 + 0.182T_{10} = -2.40 \quad (5)$$

Nodes 6 and 11

$$k_s\Delta x(T_1 - T_6)/\Delta y + k_s\Delta y(T_7 - T_6)/\Delta x + k_s\Delta x(T_{11} - T_6)/\Delta y = 0$$

$$T_1 - 3T_6 + T_7 + T_{11} = 0 \quad T_6 - 3T_{11} + T_{12} + T_{16} = 0 \quad (6,11)$$

Nodes 7, 8, 12, 13, 14 Treat as interior points,

$$T_2 + T_6 - 4T_7 + T_8 + T_{12} = 0 \quad T_3 + T_7 - 4T_8 + T_9 + T_{13} = 0 \quad (7,8)$$

$$T_7 + T_{11} - 4T_{12} + T_{13} + T_{17} = 0 \quad T_8 + T_{12} - 4T_{13} + T_{14} + T_{18} = 0 \quad (12,13)$$

$$T_9 + T_{13} - 4T_{14} + T_{15} + T_{19} = 0 \quad (14)$$

Node 9

$$k_s\Delta y \frac{T_8 - T_9}{\Delta x} + \frac{T_4 - T_9}{(\Delta y/2)/k_c\Delta x + (\Delta y/2)/k_s\Delta x} + k_s\Delta y \frac{T_{10} - T_9}{\Delta x} + k_s\Delta x \frac{T_{14} - T_9}{\Delta y} = 0$$

$$1.82T_4 + T_8 - 4.82T_9 + T_{10} + T_{14} = 0 \quad (9)$$

Node 10 Using the result of Node 9 and considering symmetry,

$$1.82T_5 + 2T_9 - 4.82T_{10} + T_{15} = 0 \quad (10)$$

Node 15 Interior point considering symmetry $T_{10} + 2T_{14} - 4T_{15} + T_{20} = 0 \quad (15)$

Node 16 By inspection, $T_{11} - 2T_{16} + T_{17} = 0 \quad (16)$

Continued

PROBLEM 4.74 (Cont.)

Nodes 17, 18, 19, 20

$$T_{12} + T_{16} - 3T_{17} + T_{18} = 0 \quad T_{13} + T_{17} - 3T_{18} + T_{19} = 0 \quad (17,18)$$

$$T_{14} + T_{18} - 3T_{19} + T_{20} = 0 \quad T_{15} + 2T_{19} - 3T_{20} = 0 \quad (19,20)$$

Using the matrix inversion method, the above system of finite-difference equations is written in matrix notation, Eq. 4.48, $[A][T] = [C]$ where

$$[A] = \begin{bmatrix} -2.3 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & -3.3 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & -4.12 & 1.82 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1.82 & -1.39 & 1 & 0 & 0 & 0 & 0 & 1.82 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 & -2.21 & 0 & 0 & 0 & 0 & 0 & 1.82 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & -3 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1.82 & 0 & 0 & 0 & 1 & -4.82 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1.82 & 0 & 0 & 0 & 2 & -4.82 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & -3 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 2 & -4 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & -2 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & -3 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & -3 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & -3 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 2 & -3 \end{bmatrix} \quad [C] = \begin{bmatrix} -6 \\ -6 \\ -6 \\ -2.4 \\ -2.4 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

and the temperature distribution ($^{\circ}\text{C}$), in geometrical representation, is

34.46	36.13	40.41	45.88	46.23
37.13	38.37	40.85	43.80	44.51
38.56	39.38	40.81	42.72	42.78
39.16	39.77	40.76	41.70	42.06

The maximum temperature is $T_5 = 46.23^{\circ}\text{C}$ which is indeed less than 85°C .

COMMENTS: (1) The convection process for the energy balances of Nodes 1 through 5 were simplified by assuming the node temperature is also that of the surface. Considering

Node 2, the energy balance processes for q_a , q_b and q_c are identical (see Eq. (2)); however,

$$q_{\text{conv}} = \frac{T_{\infty} - T_2}{1/h + \Delta y/2k} \approx h(T_{\infty} - T_2)$$

where $h\Delta y/2k = 5 \text{ W/m}^2 \cdot \text{K} \times 0.003 \text{ m} / 2 \times 50 \text{ W/m} \cdot \text{K} = 1.5 \times 10^{-4} \ll 1$. Hence, for this situation, the simplification is justified.

PROBLEM 4.75

KNOWN: Electronic device cooled by conduction to a heat sink.

FIND: (a) Beginning with a symmetrical element, find the thermal resistance per unit depth between the device and lower surface of the sink, $R'_{t,d-s}$ (m·K/W) using a coarse (5x5) nodal network, determine $R'_{t,d-s}$; (b) Using nodal networks with finer grid spacings, determine the effect of grid size on the precision of the thermal resistance calculation; (c) Using a fine nodal network, determine the effect of device width on $R'_{t,d-s}$ with $w_d/w_s = 0.175, 0.275, 0.375$ and 0.475 keeping w_s and L fixed.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, and (3) No internal generation, (4) Top surface not covered by device is insulated.

ANALYSIS: (a) The coarse 5x5 nodal network is shown in the sketch including the nodes adjacent to the symmetry lines and the adiabatic surface. As such, all the finite-difference equations are interior nodes and can be written by inspection directly onto the IHT workspace. Alternatively, one could use the *IHT Finite-Difference Equations Tool*. The temperature distribution (°C) is tabulated in the same arrangement as the nodal network.

85.00	85.00	62.31	53.26	50.73
65.76	63.85	55.49	50.00	48.20

37.18	36.70	35.47	34.37	33.95
25.00	25.00	25.00	25.00	25.00

The thermal resistance between the device and sink per unit depth is

$$R'_{t,s-d} = \frac{T_d - T_s}{2q'_{tot}}$$

Continued...

PROBLEM 4.75 (Cont.)

Performing an energy balance on the device nodes, find

$$q'_{\text{tot}} = q'_a + q'_b + q'_c$$

$$q'_{\text{tot}} = k(\Delta y/2) \frac{T_d - T_1}{\Delta x} + k\Delta x \frac{T_d - T_5}{\Delta y} + k(\Delta x/2) \frac{T_d - T_4}{\Delta y}$$

$$q'_{\text{tot}} = 300 \text{ W/m} \cdot \text{K} \left[(85 - 62.31)/2 + (85 - 63.85) + (85 - 65.76)/2 \right] \text{ K} = 1.263 \times 10^4 \text{ W/m}$$

$$R'_{t,s-d} = \frac{(85 - 25) \text{ K}}{2 \times 1.263 \times 10^4 \text{ W/m}} = 2.38 \times 10^{-3} \text{ m} \cdot \text{K/W}$$

<

(b) The effect of grid size on the precision of the thermal resistance estimate should be tested by systematically reducing the nodal spacing Δx and Δy . This is a considerable amount of work even with IHT since the equations need to be individually entered. A more generalized, powerful code would be required which allows for automatically selecting the grid size. Using FEHT, a finite-element package, with eight elements across the device, representing a much finer mesh, we found

$$R'_{t,s-d} = 3.64 \times 10^{-3} \text{ m} \cdot \text{K/W}$$

(c) Using the same tool, with the finest mesh, the thermal resistance was found as a function of w_d/w_s with fixed w_s and L .

As expected, as w_d increases, $R'_{t,d-s}$ decreases, and eventually will approach the value for the rectangular domain (ii). The spreading effect is shown for the base case, $w_d/w_s = 0.375$, where the thermal resistance of the sink is less than that for the rectangular domain (i).

COMMENTS: It is useful to compare the results for estimating the thermal resistance in terms of precision requirements and level of effort,

	$R'_{t,d-s} \times 10^3 \text{ (m} \cdot \text{K/W)}$
Rectangular domain (i)	4.44
Flux plot	3.03
Rectangular domain (ii)	1.67
FDE, 5x5 network	2.38
FEA, fine mesh	3.64

PROBLEM 4.76

KNOWN: Nodal network and boundary conditions for a water-cooled cold plate.

FIND: (a) Steady-state temperature distribution for prescribed conditions, (b) Means by which operation may be extended to larger heat fluxes.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: Finite-difference equations must be obtained for each of the 28 nodes. Applying the energy balance method to regions 1 and 5, which are similar, it follows that

$$\text{Node 1: } (\Delta y / \Delta x) T_2 + (\Delta x / \Delta y) T_6 - [(\Delta y / \Delta x) + (\Delta x / \Delta y)] T_1 = 0$$

$$\text{Node 5: } (\Delta y / \Delta x) T_4 + (\Delta x / \Delta y) T_{10} - [(\Delta y / \Delta x) + (\Delta x / \Delta y)] T_5 = 0$$

Nodal regions 2, 3 and 4 are similar, and the energy balance method yields a finite-difference equation of the form

Nodes 2,3,4:

$$(\Delta y / \Delta x) (T_{m-1,n} + T_{m+1,n}) + 2(\Delta x / \Delta y) T_{m,n-1} - 2[(\Delta y / \Delta x) + (\Delta x / \Delta y)] T_{m,n} = 0$$

Energy balances applied to the remaining combinations of similar nodes yield the following finite-difference equations.

Continued...

PROBLEM 4.76 (Cont.)

$$\begin{aligned}
 \text{Nodes 6, 14: } & (\Delta x/\Delta y)T_1 + (\Delta y/\Delta x)T_7 - [(\Delta x/\Delta y) + (\Delta y/\Delta x) + (h\Delta x/k)]T_6 = -(h\Delta x/k)T_\infty \\
 & (\Delta x/\Delta y)T_{19} + (\Delta y/\Delta x)T_{15} - [(\Delta x/\Delta y) + (\Delta y/\Delta x) + (h\Delta x/k)]T_{14} = -(h\Delta x/k)T_\infty \\
 \text{Nodes 7, 15: } & (\Delta y/\Delta x)(T_6 + T_8) + 2(\Delta x/\Delta y)T_2 - 2[(\Delta y/\Delta x) + (\Delta x/\Delta y) + (h\Delta x/k)]T_7 = -(2h\Delta x/k)T_\infty \\
 & (\Delta y/\Delta x)(T_{14} + T_{16}) + 2(\Delta x/\Delta y)T_{20} - 2[(\Delta y/\Delta x) + (\Delta x/\Delta y) + (h\Delta x/k)]T_{15} = -(2h\Delta x/k)T_\infty \\
 \text{Nodes 8, 16: } & (\Delta y/\Delta x)T_7 + 2(\Delta y/\Delta x)T_9 + (\Delta x/\Delta y)T_{11} + 2(\Delta x/\Delta y)T_3 - [3(\Delta y/\Delta x) + 3(\Delta x/\Delta y) \\
 & \quad + (h/k)(\Delta x + \Delta y)]T_8 = -(h/k)(\Delta x + \Delta y)T_\infty \\
 & (\Delta y/\Delta x)T_{15} + 2(\Delta y/\Delta x)T_{17} + (\Delta x/\Delta y)T_{11} + 2(\Delta x/\Delta y)T_{21} - [3(\Delta y/\Delta x) + 3(\Delta x/\Delta y) \\
 & \quad + (h/k)(\Delta x + \Delta y)]T_{16} = -(h/k)(\Delta x + \Delta y)T_\infty \\
 \text{Node 11: } & (\Delta x/\Delta y)T_8 + (\Delta x/\Delta y)T_{16} + 2(\Delta y/\Delta x)T_{12} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x) + (h\Delta y/k)]T_{11} = -(2h\Delta y/k)T_\infty \\
 \text{Nodes 9, 12, 17, 20, 21, 22: } & (\Delta y/\Delta x)T_{m-1,n} + (\Delta y/\Delta x)T_{m+1,n} + (\Delta x/\Delta y)T_{m,n+1} + (\Delta x/\Delta y)T_{m,n-1} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{m,n} = 0 \\
 \text{Nodes 10, 13, 18, 23: } & (\Delta x/\Delta y)T_{n+1,m} + (\Delta x/\Delta y)T_{n-1,m} + 2(\Delta y/\Delta x)T_{m-1,n} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{m,n} = 0 \\
 \text{Node 19: } & (\Delta x/\Delta y)T_{14} + (\Delta x/\Delta y)T_{24} + 2(\Delta y/\Delta x)T_{20} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{19} = 0 \\
 \text{Nodes 24, 28: } & (\Delta x/\Delta y)T_{19} + (\Delta y/\Delta x)T_{25} - [(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{24} = -(q''_0\Delta x/k) \\
 & (\Delta x/\Delta y)T_{23} + (\Delta y/\Delta x)T_{27} - [(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{28} = -(q''_0\Delta x/k) \\
 \text{Nodes 25, 26, 27: } & (\Delta y/\Delta x)T_{m-1,n} + (\Delta y/\Delta x)T_{m+1,n} + 2(\Delta x/\Delta y)T_{m,n+1} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{m,n} = -(2q''_0\Delta x/k)
 \end{aligned}$$

Evaluating the coefficients and solving the equations simultaneously, the steady-state temperature distribution ($^{\circ}\text{C}$), tabulated according to the node locations, is:

23.77	23.91	24.27	24.61	24.74
23.41	23.62	24.31	24.89	25.07
		25.70	26.18	26.33
28.90	28.76	28.26	28.32	28.35
30.72	30.67	30.57	30.53	30.52
32.77	32.74	32.69	32.66	32.65

Alternatively, the foregoing results may readily be obtained by accessing the *IHT Tools* pad and using the *2-D, SS, Finite-Difference Equations* options (model equations are appended). Maximum and minimum cold plate temperatures are at the bottom (T_{24}) and top center (T_1) locations respectively.

(b) For the prescribed conditions, the maximum allowable temperature ($T_{24} = 40^{\circ}\text{C}$) is reached when $q''_0 = 1.407 \times 10^5 \text{ W/m}^2$ (14.07 W/cm^2). Options for extending this limit could include use of a copper cold plate ($k \approx 400 \text{ W/m}\cdot\text{K}$) and/or increasing the convection coefficient associated with the coolant. With $k = 400 \text{ W/m}\cdot\text{K}$, a value of $q''_0 = 17.37 \text{ W/cm}^2$ may be maintained. With $k = 400 \text{ W/m}\cdot\text{K}$ and $h = 10,000 \text{ W/m}^2\cdot\text{K}$ (a practical upper limit), $q''_0 = 28.65 \text{ W/cm}^2$. Additional, albeit small, improvements may be realized by relocating the coolant channels closer to the base of the cold plate.

COMMENTS: The accuracy of the solution may be confirmed by verifying that the results satisfy the overall energy balance

$$\begin{aligned}
 q''_0(4\Delta x) = h[& (\Delta x/2)(T_6 - T_\infty) + \Delta x(T_7 - T_\infty) + (\Delta x + \Delta y)(T_8 - T_\infty)/2 \\
 & + \Delta y(T_{11} - T_\infty) + (\Delta x + \Delta y)(T_{16} - T_\infty)/2 + \Delta x(T_{15} - T_\infty) + (\Delta x/2)(T_{14} - T_\infty)].
 \end{aligned}$$

PROBLEM 4.77

KNOWN: Heat sink for cooling computer chips fabricated from copper with microchannels passing fluid with prescribed temperature and convection coefficient.

FIND: (a) Using a square nodal network with 100 μm spatial increment, determine the temperature distribution and the heat rate to the coolant per unit channel length for maximum allowable chip temperature $T_{c,\max} = 75^\circ\text{C}$; estimate the thermal resistance between the chip surface and the fluid, $R'_{t,c-f}$ ($\text{m}\cdot\text{K}/\text{W}$); maximum allowable heat dissipation for a chip that measures 10 x 10 mm on a side; (b) The effect of grid spacing by considering spatial increments of 50 and 25 μm ; and (c) Consistent with the requirement that $a + b = 400 \mu\text{m}$, explore altering the sink dimensions to decrease the thermal resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, and (3) Convection coefficient is uniform over the microchannel surface and independent of the channel dimensions and shape.

ANALYSIS: (a) The square nodal network with $\Delta x = \Delta y = 100 \mu\text{m}$ is shown below. Considering symmetry, the nodes 1, 2, 3, 4, 7, and 9 can be treated as interior nodes and their finite-difference equations representing nodal energy balances can be written by inspection. Using the, *IHT Finite-Difference Equations Tool*, appropriate FDEs for the nodes experiencing surface convection can be obtained. The IHT code along with results is included in the Comments. Having the temperature distribution, the heat rate to the coolant per unit channel length for two symmetrical elements can be obtained by applying Newton's law of cooling to the surface nodes,

$$q'_{cv} = 2 \left[h \left(\Delta y/2 + \Delta x/2 \right) (T_5 - T_\infty) + h \left(\Delta x/2 \right) (T_6 - T_\infty) + h \left(\Delta y \right) (T_8 - T_\infty) + h \left(\Delta y/2 \right) (T_{10} - T_\infty) \right]$$

$$q'_{cv} = 2 \times 30,000 \text{ W/m}^2 \cdot \text{K} \times 100 \times 10^{-6} \text{ m} \left[(74.02 - 25) + (74.09 - 25)/2 + (73.60 - 25) + (73.37 - 25)/2 \right] \text{ K}$$

$$q'_{cv} = 878 \text{ W/m} \quad <$$

The thermal resistance between the chip and fluid per unit length for each microchannel is

$$R'_{t,c-f} = \frac{T_c - T_\infty}{q'_{cv}} = \frac{(75 - 25)^\circ \text{C}}{878 \text{ W/m}} = 5.69 \times 10^{-2} \text{ m} \cdot \text{K/W} \quad <$$

The maximum allowable heat dissipation for a 10 mm x 10 mm chip is

$$P_{\text{chip,max}} = q''_c \times A_{\text{chip}} = 2.20 \times 10^6 \text{ W/m}^2 \times (0.01 \times 0.01) \text{ m}^2 = 220 \text{ W} \quad <$$

where $A_{\text{chip}} = 10 \text{ mm} \times 10 \text{ mm}$ and the heat flux on the chip surface ($w_f + w_s$) is

$$q''_c = q'_{cv} / (w_f + w_s) = 878 \text{ W/m} / (200 + 200) \times 10^{-6} \text{ m} = 2.20 \times 10^6 \text{ W/m}^2$$

Continued...

PROBLEM 4.77 (Cont.)

(b) To investigate the effect of grid spacing, the analysis was repeated with a spatial increment of $50\ \mu\text{m}$ (32 nodes as shown above) with the following results

$$q'_{\text{cv}} = 881\ \text{W/m} \quad R'_{\text{t,c-f}} = 5.67 \times 10^{-2}\ \text{m} \cdot \text{K/W} \quad <$$

Using a finite-element package with a mesh around $25\ \mu\text{m}$, we found $R'_{\text{t,c-f}} = 5.70 \times 10^{-2}\ \text{m} \cdot \text{K/W}$ which suggests the grid spacing effect is not very significant.

(c) Requiring that the overall dimensions of the symmetrical element remain unchanged, we explored what effect changes in the microchannel cross-section would have on the overall thermal resistance, $R'_{\text{t,c-f}}$. It is important to recognize that the sink conduction path represents the dominant resistance, since for the convection process

$$R'_{\text{t,cv}} = 1/A'_s = 1/\left(30,000\ \text{W/m}^2 \cdot \text{K} \times 600 \times 10^{-6}\ \text{m}\right) = 5.55 \times 10^{-2}\ \text{m} \cdot \text{K/W}$$

where $A'_s = (w_f + 2b) = 600\ \mu\text{m}$.

Using a finite-element package, the thermal resistances per unit length for three additional channel cross-sections were determined and results summarized below.

Case	Microchannel (μm)		$R'_{\text{t,c-s}} \times 10^2$ ($\text{m} \cdot \text{K/W}$)
	Height	Half-width	
A	200	100	5.70
B	133	150	6.12
C	300	100	4.29
D	250	150	4.25

PROBLEM 4.78

KNOWN: Longitudinal rib ($k = 10 \text{ W/m}\cdot\text{K}$) with rectangular cross-section with length $L = 8 \text{ mm}$ and width $w = 4 \text{ mm}$. Base temperature T_b and convection conditions, T_∞ and h , are prescribed.

FIND: (a) Temperature distribution and fin base heat rate using a finite-difference method with $\Delta x = \Delta y = 2 \text{ mm}$ for a total of $5 \times 3 = 15$ nodal points and regions; compare results with those obtained assuming one-dimensional heat transfer in rib; and (b) The effect of grid spacing by reducing nodal spacing to $\Delta x = \Delta y = 1 \text{ mm}$ for a total of $9 \times 3 = 27$ nodal points and regions considering symmetry of the centerline; and (c) A criterion for which the one-dimensional approximation is reasonable; compare the heat rate for the range $1.5 \leq L/w \leq 10$, keeping L constant, as predicted by the two-dimensional, finite-difference method and the one-dimensional fin analysis.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, and (3) Convection coefficient uniform over rib surfaces, including tip.

ANALYSIS: (a) The rib is represented by a 5×3 nodal grid as shown above where the symmetry plane is an adiabatic surface. The *IHT Tool, Finite-Difference Equations, for Two-Dimensional, Steady-State* conditions is used to formulate the nodal equations (see Comment 2 below) which yields the following nodal temperatures ($^{\circ}\text{C}$)

45	39.3	35.7	33.5	32.2
45	40.0	36.4	34.0	32.6
45	39.3	35.7	33.5	32.2

Note that the fin tip temperature is

$$T_{\text{tip}} = T_{12} = 32.6^{\circ}\text{C}$$

<

The fin heat rate per unit width normal to the page, q'_{fin} , can be determined from energy balances on the three base nodes as shown in the schematic below.

$$q'_{\text{fin}} = q'_a + q'_b + q'_c + q'_d + q'_e$$

$$q'_a = h(\Delta x/2)(T_b - T_\infty)$$

$$q'_b = k(\Delta y/2)(T_b - T_1)/\Delta x$$

$$q'_c = k(\Delta y)(T_b - T_5)/\Delta x$$

$$q'_d = k(\Delta y/2)(T_b - T_9)/\Delta x$$

$$q'_e = h(\Delta x/2)(T_b - T_\infty)$$

Continued...

PROBLEM 4.78 (Cont.)

Substituting numerical values, find

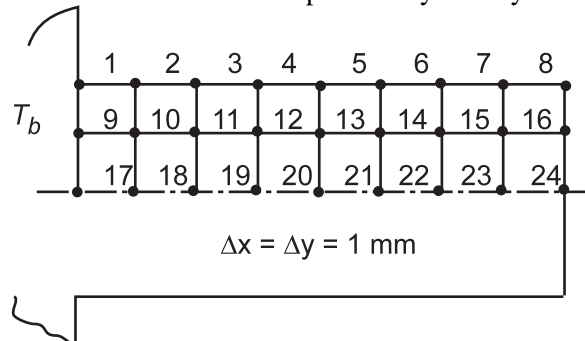

$$q'_{\text{fin}} = (12.0 + 28.4 + 50.0 + 28.4 + 12.0) \text{ W/m} = 130.8 \text{ W/m}$$

Using the *IHT Model, Extended Surfaces, Heat Rate and Temperature Distributions for Rectangular, Straight Fins*, with convection tip condition, the one-dimensional fin analysis yields

$$q'_f = 131 \text{ W/m}$$

$$T_{\text{tip}} = 32.2^\circ \text{C}$$

(b) With $\Delta x = L/8 = 1 \text{ mm}$ and $\Delta y = 1 \text{ mm}$, for a total of $9 \times 3 = 27$ nodal points and regions, the grid appears as shown below. Note the rib centerline is a plane of symmetry.

Using the same IHT FDE Tool as above with an appropriate expression for the fin heat rate, Eq. (1), the fin heat rate and tip temperature were determined.

	1-D analysis	2-D analysis (nodes)	
		(5 × 3)	(9 × 3)
$T_{\text{tip}} (^\circ\text{C})$	32.2	32.6	32.6
$q'_{\text{fin}} (\text{W/m})$	131	131	129

(c) To determine when the one-dimensional approximation is reasonable, consider a rib of constant length, $L = 8 \text{ mm}$, and vary the thickness w for the range $1.5 \leq L/w \leq 10$. Using the above IHT model for the 27 node grid, the fin heat rates for 1-D, q'_{1d} , and 2-D, q'_{2d} , analysis were determined as a function of w with the error in the approximation evaluated as

$$\text{Error}(\%) = (q'_{2d} - q'_{1d}) \times 100 / q'_{1d}$$

Note that for small L/w , a thick rib, the 1-D approximation is poor. For large L/w , a thin rib which approximates a fin, we would expect the 1-D approximation to become increasingly more satisfactory. The discrepancy at large L/w must be due to discretization error; that is, the grid is too coarse to accurately represent the slender rib.

PROBLEM 4.79

KNOWN: Bottom half of an I-beam exposed to hot furnace gases.

FIND: (a) The heat transfer rate per unit length into the beam using a coarse nodal network (5×4) considering the temperature distribution across the web is uniform and (b) Assess the reasonableness of the uniform web-flange interface temperature assumption.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, and (2) Constant properties.

ANALYSIS: (a) The symmetrical section of the I-beam is shown in the Schematic above indicating the web-flange interface temperature is uniform, $T_w = 100^\circ\text{C}$. The nodal arrangement to represent this system is shown below. The nodes on the line of symmetry have been shown for convenience in deriving the nodal finite-difference equations.

Using the *IHT Finite-Difference Equations Tool*, the set of nodal equations can be readily formulated. The temperature distribution ($^\circ\text{C}$) is tabulated in the same arrangement as the nodal network.

100.00	100.00	215.8	262.9	284.8
166.6	177.1	222.4	255.0	272.0
211.7	219.5	241.9	262.7	274.4
241.4	247.2	262.9	279.3	292.9

The heat rate to the beam can be determined from energy balances about the web-flange interface nodes as shown in the sketch below.

Continued...

PROBLEM 4.79 (Cont.)

$$q'_w = q'_a + q'_b + q'_c$$

$$q'_w = k(\Delta y/2) \frac{T_1 - T_w}{\Delta x} + k(\Delta x) \frac{T_5 - T_w}{\Delta y} + k(\Delta x/2) \frac{T_4 - T_w}{\Delta y}$$

$$q'_w = 10 \text{ W/m} \cdot \text{K} \left[(215.8 - 100)/2 + (177.1 - 100) + (166.6 - 100)/2 \right] \text{ K} = 1683 \text{ W/m} \quad <$$

(b) The schematic below poses the question concerning the reasonableness of the uniform temperature assumption at the web-flange interface. From the analysis above, note that $T_1 = 215.8^\circ\text{C}$ vs. $T_w = 100^\circ\text{C}$ indicating that this assumption is a poor one. This L-shaped section has strong two-dimensional behavior. To illustrate the effect, we performed an analysis with $T_w = 100^\circ\text{C}$ located nearly $2 \times$ times further up the web than it is wide. For this situation, the temperature difference at the web-flange interface across the width of the web was nearly 40°C . The steel beam with its low thermal conductivity has substantial internal thermal resistance and given the L-shape, the uniform temperature assumption (T_w) across the web-flange interface is inappropriate.

PROBLEM 4.80

KNOWN: Plane composite wall with exposed surfaces maintained at fixed temperatures. Material A has temperature-dependent thermal conductivity.

FIND: Heat flux through the wall (a) assuming a uniform thermal conductivity in material A evaluated at the average temperature of the section, and considering the temperature-dependent thermal conductivity of material A using (b) a finite-difference method of solution in IHT with a space increment of 1 mm and (c) the finite-element method of FEHT.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) No thermal contact resistance between the materials, and (3) No internal generation.

ANALYSIS: (a) From the thermal circuit in the above schematic, the heat flux is

$$q''_x = \frac{T_1 - T_2}{R''_A + R''_B} = \frac{T_{AB} - T_2}{R''_B} \quad (1, 2)$$

and the thermal resistances of the two sections are

$$R''_A = L_A / k_A \quad R''_B = L_B / k_B \quad (3, 4)$$

The thermal conductivity of material A is evaluated at the average temperature of the section

$$k_A = k_o \left\{ 1 + \alpha \left[(T_1 + T_{AB}) / 2 - T_o \right] \right\} \quad (5)$$

Substituting numerical values and solving the system of equations simultaneously in IHT, find

$$T_{AB} = 563.2 \text{ K} \quad q''_x = 52.64 \text{ kW/m}^2 \quad <$$

(b) The nodal arrangement for the finite-difference method of solution is shown in the schematic below. FDEs must be written for the internal nodes (02 – 10, 12 – 15) and the A-B interface node (11) considering in section A, the temperature-dependent thermal conductivity.

Interior Nodes, Section A ($m = 02, 03 \dots 10$)

Referring to the schematic below, the energy balance on node m is written in terms of the heat fluxes at the control surfaces using Fourier's law with the thermal conductivity based upon the average temperature of adjacent nodes. The heat fluxes into node m are

Continued

PROBLEM 4.80 (Cont.)

$$q_c'' = k_a (m, m+1) \frac{T_{m+1} - T_m}{\Delta x} \quad (1)$$

$$q_d'' = k_a (m-1, m) \frac{T_m - T_{m-1}}{\Delta x} \quad (2)$$

and the FDEs are obtained from the energy balance written as

$$q_c'' + q_d'' = 0 \quad (3)$$

$$k_a (m, m+1) \frac{T_{m+1} - T_m}{\Delta x} + k_a (m-1, m) \frac{T_m - T_{m-1}}{\Delta x} = 0 \quad (4)$$

where the thermal conductivities averaged over the path between the nodes are expressed as

$$k_a (m-1, m) = k_o \left\{ 1 + \alpha \left[(T_{m-1} + T_m) / 2 - T_o \right] \right\} \quad (5)$$

$$k_a (m, m+1) = k_o \left\{ 1 + \alpha \left[(T_m + T_{m+1}) / 2 - T_o \right] \right\} \quad (6)$$

A-B Interface Node 11

Referring to the above schematic, the energy balance on the interface node, $q_c'' + q_d'' = 0$, has the form

$$k_b \frac{T_{12} - T_{11}}{\Delta x} + k_a (10, 11) \frac{T_{10} - T_{11}}{\Delta x} = 0 \quad (7)$$

where the thermal conductivity in the section A path is

$$k (10, 11) = k_o \left\{ 1 + \left[(T_{10} + T_{11}) / 2 - T_o \right] \right\} \quad (8)$$

Interior Nodes, Section B ($n = 12 \dots 15$)

Since the thermal conductivity in Section B is uniform, the FDEs have the form

$$T_n = (T_{n-1} + T_{n+1}) / 2 \quad (9)$$

And the heat flux in the x-direction is

$$q_x'' = k_b \frac{T_n - T_{n+1}}{\Delta x} \quad (10)$$

Finite-Difference Method of Solution

The foregoing FDE equations for section A nodes ($m = 02$ to 10), the AB interface node and their respective expressions for the thermal conductivity, $k (m, m+1)$, and for section B nodes are entered into the IHT workspace and solved for the temperature distribution. The heat flux can be evaluated using Eq. (2) or (10). A portion of the IHT code is contained in the Comments, and the results of the analysis are tabulated below.

$$T_{11} = T_{AB} = 563.2 \text{ K}$$

$$q_x'' = 52.64 \text{ kW} / \text{m}^2$$

<

Continued

PROBLEM 4.80 (Cont.)

(c) The finite-element method of FEHT can be used readily to obtain the heat flux considering the temperature-dependent thermal conductivity of section A. Draw the composite wall outline with properly scaled section thicknesses in the x-direction with an arbitrary y-direction dimension. In the *Specify | Materials Properties* box for the thermal conductivity, specify k_a as $4.4*[1 + 0.008*(T - 300)]$ having earlier selected *Set | Temperatures in K*. The results of the analysis are

$$T_{AB} = 563 \text{ K} \qquad q_x'' = 52.6 \text{ kW/m}^2 \qquad <$$

COMMENTS: (1) The results from the three methods of analysis compare very well. Because the thermal conductivity in section A is linear, and moderately dependent on temperature, the simplest method of using an overall section average, part (a), is recommended. This same method is recommended when using tabular data for temperature-dependent properties.

(2) For the finite-difference method of solution, part (b), the heat flux was evaluated at several nodes within section A and in section B with identical results. This is a consequence of the technique for averaging k_a over the path between nodes in computing the heat flux into a node.

(3) To illustrate the use of IHT in solving the finite-difference method of solution, lines of code for representative nodes are shown below.

```
// FDEs – Section A
k01_02 * (T01-T02)/deltax + k02_03 * (T03-T02)/deltax = 0
k01_02 = ko * (1+ alpha * ((T01 + T02)/2 – To))
k02_03 = ko * (1 + alpha * ((T02 + T03)/2 – To))

k02_03 * (T02 – T03)/deltax + k03_04 * (T04 – T03)/deltax = 0
k03_04 = ko * (1 + alpha * ((T03 + T04)/2 – To))

// Interface, node 11
k11 * (T10 – T11)/deltax + kb * (T12 – T11)/deltax = 0
k11 = ko * (1 + alpha * ((T10 + T11)/2 – To))

// Section B (using Tools/FDE/One-dimensional/Steady-state)
/* Node 12: interior node; */
0.0 = fd_1d_int(T12, T13, T11, kb, qdot, deltax)
```

(4) The solved models for Text Examples 4.3 and 4.4, plus the tutorial of the User's Manual, provide background for developing skills in using FEHT.

PROBLEM 4.81

KNOWN: Upper surface of a platen heated by hot fluid through the flow channels is used to heat a process fluid.

FIND: (a) The maximum allowable spacing, W , between channel centerlines that will provide a uniform temperature requirement of 5°C on the upper surface of the platen, and (b) Heat rate per unit length from the flow channel for this condition.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction with constant properties, and (2) Lower surface of platen is adiabatic.

ANALYSIS: As shown in the schematic above for a symmetrical section of the platen-flow channel arrangement, the temperature uniformity requirement will be met when $T_1 - T_2 = 5^\circ\text{C}$. The maximum temperature, T_1 , will occur directly over the flow channel centerline, while the minimum surface temperature, T_2 , will occur at the mid-span between channel centerlines.

We chose to use FEHT to obtain the temperature distribution and heat rate for guessed values of the channel centerline spacing, W . The following method of solution was used: (1) Make an initial guess value for W ; try $W = 100$ mm, (2) Draw an outline of the symmetrical section, and assign properties and boundary conditions, (3) Make a copy of this file so that in your second trial, you can use the *Draw | Move Node* option to modify the section width, $W/2$, larger or smaller, (4) Draw element lines within the outline to create triangular elements, (5) Use the *Draw | Reduce Mesh* command to generate a suitably fine mesh, then solve for the temperature distribution, (6) Use the *View | Temperatures* command to determine the temperatures T_1 and T_2 , (7) If, $T_1 - T_2 \approx 5^\circ\text{C}$, use the *View | Heat Flows* command to find the heat rate, otherwise, change the width of the section outline and repeat the analysis. The results of our three trials are tabulated below.

Trial	W (mm)	T_1 ($^\circ\text{C}$)	T_2 ($^\circ\text{C}$)	$T_1 - T_2$ ($^\circ\text{C}$)	q' (W/m)
1	100	108	98	10	--
2	60	119	118	1	--
3	80	113	108	5	1706

COMMENTS: (1) In addition to the tutorial example in the FEHT User's Manual, the solved models for Examples 4.3 and 4.4 of the Text are useful for developing skills in using this problem-solving tool.

(2) An alternative numerical method of solution would be to create a nodal network, generate the finite-difference equations and solve for the temperature distribution and the heat rate. The FDEs should allow for a non-square grid, $\Delta x \neq \Delta y$, so that different values for $W/2$ can be accommodated by changing the value of Δx . Even using the IHT tool for building FDEs (*Tools | Finite-Difference Equations | Steady-State*) this method of solution is very labor intensive because of the large number of nodes required for obtaining good estimates.

PROBLEM 4.82

KNOWN: Silicon chip mounted in a dielectric substrate. One surface of system is convectively cooled, while the remaining surfaces are well insulated. See Problem 4.75. Use the finite-element software *FEHT* as your analysis tool.

FIND: (a) The temperature distribution in the substrate-chip system; does the maximum temperature exceed 85°C ?; (b) Volumetric heating rate that will result in a maximum temperature of 85°C ; and (c) Effect of reducing thickness of substrate from 12 to 6 mm, keeping all other dimensions unchanged with $\dot{q} = 1 \times 10^7 \text{ W/m}^3$; maximum temperature in the system for these conditions, and fraction of the power generated within the chip removed by convection directly from the chip surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction in system, and (3) Uniform convection coefficient over upper surface.

ANALYSIS: Using *FEHT*, the symmetrical section is represented in the workspace as two connected regions, chip and substrate. *Draw* first the chip outline; *Specify* the material and generation parameters. Now, *Draw* the outline of the substrate, connecting the nodes of the interfacing surfaces; *Specify* the material parameters for this region. Finally, *Assign* the *Boundary Conditions*: zero heat flux for the symmetry and insulated surfaces, and convection for the upper surface. *Draw Element Lines*, making the triangular elements near the chip and surface smaller than near the lower insulated boundary as shown in a copy of the *FEHT* screen on the next page. Use the *Draw/Reduce Mesh* command and *Run* the model.

(a) Use the *View/Temperature* command to see the nodal temperatures through out the system. As expected, the hottest location is on the centerline of the chip at the bottom surface. At this location, the temperature is

$$T(0, 9 \text{ mm}) = 46.7^\circ\text{C}$$

<

(b) Run the model again, with different values of the generation rate until the temperature at this location is $T(0, 9 \text{ mm}) = 85^\circ\text{C}$, finding

$$\dot{q} = 2.43 \times 10^7 \text{ W/m}^3$$

<

Continued

PROBLEM 4.82 (Cont.)

(c) Returning to the model code with the conditions of part (a), reposition the nodes on the lower boundary, as well as the intermediate ones, to represent a substrate that is of 6-mm, rather than 12-mm thickness. Find the maximum temperature as

$$T(0, 3 \text{ mm}) = 47.5^\circ\text{C}$$

<

Using the *View/Heat Flow* command, click on the adjacent line segments forming the chip surface exposed to the convection process. The heat rate per unit width (normal to the page) is

$$q'_{\text{chip}, \text{cv}} = 60.26 \text{ W/m}$$

The total heat generated within the chip is

$$q'_{\text{tot}} = \dot{q}(L/6 \times H/4) = 1 \times 10^7 \text{ W/m}^3 \times (0.0045 \times 0.003) \text{ m}^2 = 135 \text{ W/m}$$

so that the fraction of the power dissipated by the chip that is convected directly to the coolant stream is

$$F = q'_{\text{chip}, \text{cv}} / q'_{\text{tot}} = 60.26 / 135 = 45\%$$

<

COMMENTS: (1) Comparing the maximum temperatures for the system with the 12-mm and 6-mm thickness substrates, note that the effect of halving the substrate thickness is to raise the maximum temperature by less than 1°C. The thicker substrate does not provide significantly improved heat removal capability.

(2) Without running the code for part (b), estimate the magnitude of \dot{q} that would make $T(0, 9 \text{ mm}) = 85^\circ\text{C}$. Did you get $\dot{q} = 2.43 \times 10^7 \text{ W/m}^3$? Why?

PROBLEM 4S.1

KNOWN: Long furnace of refractory brick with prescribed surface temperatures and material thermal conductivity.

FIND: Shape factor and heat transfer rate per unit length using the flux plot method

SCHEMATIC:

ASSUMPTIONS: (1) Furnace length normal to page, ℓ , \gg cross-sectional dimensions, (2) Two-dimensional, steady-state conduction, (3) Constant properties.

ANALYSIS: Considering the cross-section, the cross-hatched area represents a symmetrical element. Hence, the heat rate for the entire furnace per unit length is

$$q' = \frac{q}{\ell} = 4 \frac{S}{\ell} k (T_1 - T_2) \quad (1)$$

where S is the shape factor for the symmetrical section. Selecting three temperature increments ($N = 3$), construct the flux plot shown below.

From Equation 4S.7, $S = \frac{M\ell}{N}$ or $\frac{S}{\ell} = \frac{M}{N} = \frac{8.5}{3} = 2.83$ <

and from Equation (1), $q' = 4 \times 2.83 \times 1.2 \frac{\text{W}}{\text{m} \cdot \text{K}} (600 - 60)^\circ \text{C} = 7.34 \text{ kW/m}$. <

COMMENTS: The shape factor can also be estimated from the relations of Table 4.1. The symmetrical section consists of two plane walls (horizontal and vertical) with an adjoining edge. Using the appropriate relations, the numerical values are, in the same order,

$$S = \frac{0.75\text{m}}{0.5\text{m}} \ell + 0.54\ell + \frac{0.5\text{m}}{0.5\text{m}} \ell = 3.04\ell$$

Note that this result compares favorably with the flux plot result of 2.83ℓ .

PROBLEM 4S.2

KNOWN: Hot pipe embedded eccentrically in a circular system having a prescribed thermal conductivity.

FIND: The shape factor and heat transfer per unit length for the prescribed surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Length $\ell \gg$ diametrical dimensions.

ANALYSIS: Considering the cross-sectional view of the pipe system, the symmetrical section shown above is readily identified. Selecting four temperature increments ($N = 4$), construct the flux plot shown below.

For the pipe system, the heat rate per unit length is

$$q' = \frac{q}{\ell} = kS(T_1 - T_2) = 0.5 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 4.26(150 - 35)^\circ \text{C} = 245 \text{ W/m.}$$

<

COMMENTS: Note that in the lower, right-hand quadrant of the flux plot, the curvilinear squares are irregular. Further work is required to obtain an improved plot and, hence, obtain a more accurate estimate of the shape factor.

PROBLEM 4S.3

KNOWN: Structural member with known thermal conductivity subjected to a temperature difference.

FIND: (a) Temperature at a prescribed point P, (b) Heat transfer per unit length of the strut, (c) Sketch the 25, 50 and 75°C isotherms, and (d) Same analysis on the shape but with adiabatic-isothermal boundary conditions reversed.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: (a) When constructing the flux plot, note that the line of symmetry which passes through the point P is an isotherm as shown above. It follows that

$$T(P) = (T_1 + T_2)/2 = (100 + 0)^\circ \text{C} / 2 = 50^\circ \text{C} . \quad \angle$$

(b) The flux plot on the symmetrical section is now constructed to obtain the shape factor from which the heat rate is determined. That is, from Equation 4S.6 and 4S.7,

$$q = kS(T_1 - T_2) \quad \text{and} \quad S = M\ell/N . \quad (1,2)$$

From the plot of the symmetrical section,

$$S_o = 4.2\ell/4 = 1.05\ell .$$

For the full section of the strut,

$$M = M_o = 4.2$$

but $N = 2N_o = 8$. Hence,

$$S = S_o/2 = 0.53\ell$$

and with $q' = q/\ell$, giving

$$q'/\ell = 75 \text{ W/m} \cdot \text{K} \times 0.53(100 - 0)^\circ \text{C} = 3975 \text{ W/m} . \quad \angle$$

(c) The isotherms for $T = 50, 75$ and 100°C are shown on the flux plot. The $T = 25^\circ \text{C}$ isotherm is symmetric with the $T = 75^\circ \text{C}$ isotherm.

(d) By reversing the adiabatic and isothermal boundary conditions, the two-dimensional shape appears as shown in the sketch below. The symmetrical element to be flux plotted is the same as for the strut, except the symmetry line is now an adiabat.

Continued...

PROBLEM 4S.3 (Cont.)

From the flux plot, find $M_o = 3.4$ and $N_o = 4$, and from Equation (2)

$$S_o = M_o \ell / N_o = 3.4 \ell / 4 = 0.85 \ell \quad S = 2S_o = 1.70 \ell$$

and the heat rate per unit length from Equation (1) is

$$q' = 75 \text{ W/m} \cdot \text{K} \times 1.70 (100 - 0)^\circ\text{C} = 12,750 \text{ W/m}$$

<

From the flux plot, estimate that

$$T(P) \approx 40^\circ\text{C}.$$

<

COMMENTS: (1) By inspection of the shapes for parts (a) and (b), it is obvious that the heat rate for the latter will be greater. The calculations show the heat rate is greater by more than a factor of three.

(2) By comparing the flux plots for the two configurations, and corresponding roles of the adiabats and isotherms, would you expect the shape factor for parts (a) to be the reciprocal of part (b)?

PROBLEM 4S.4

KNOWN: Relative dimensions and surface thermal conditions of a V-grooved channel.

FIND: Flux plot and shape factor.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: With symmetry about the midplane, only one-half of the object need be considered as shown below.

Choosing 6 temperature increments ($N = 6$), it follows from the plot that $M \approx 7$. Hence from Equation 4S.7, the shape factor for the half section is

$$S = \frac{M}{N} \ell = \frac{7}{6} \ell = 1.17 \ell.$$

For the complete system, the shape factor is then

$$S = 2.34 \ell.$$

<

PROBLEM 4S.5

KNOWN: Long conduit of inner circular cross section and outer surfaces of square cross section.

FIND: Shape factor and heat rate for the two applications when outer surfaces are insulated or maintained at a uniform temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties and (3) Conduit is very long.

ANALYSIS: The adiabatic symmetry lines for each of the applications is shown above. Using the flux plot methodology and selecting four temperature increments ($N = 4$), the flux plots are as shown below.

For the symmetrical sections, $S = 2S_o$, where $S_o = M \ell / N$ and the heat rate for each application is $q = 2(S_o / \ell) k (T_1 - T_2)$.

Application	M	N	S_o / ℓ	q' (W/m)	
A	10.3	4	2.58	11,588	<
B	6.2	4	1.55	6,975	<

COMMENTS: (1) For application A, most of the heat lanes leave the inner surface (T_1) on the upper portion.

(2) For application B, most of the heat flow lanes leave the inner surface on the upper portion (that is, lanes 1-4). Because the lower, right-hand corner is insulated, the entire section experiences small heat flows (lane 6 + 0.2). Note the shapes of the isotherms near the right-hand, insulated boundary and that they intersect the boundary normally.

PROBLEM 4S.6

KNOWN: Shape and surface conditions of a support column.

FIND: (a) Heat transfer rate per unit length. (b) Height of a rectangular bar of equivalent thermal resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible three-dimensional conduction effects, (3) Constant properties, (4) Adiabatic sides.

PROPERTIES: Table A-1, Steel, AISI 1010 (323K): $k = 62.7 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) From the flux plot for the half section, $M \approx 5$ and $N \approx 8$. Hence for the full section

$$S = 2 \frac{M\ell}{N} \approx 1.25\ell$$

$$q = Sk(T_1 - T_2)$$

$$q' \approx 1.25 \times 62.7 \frac{\text{W}}{\text{m}\cdot\text{K}} (100 - 0)^\circ\text{C}$$

$$q' \approx 7.8 \text{ kW/m.}$$

(b) The rectangular bar provides for one-dimensional heat transfer. Hence,

$$q = kA \frac{(T_1 - T_2)}{H} = k(0.3\ell) \frac{(T_1 - T_2)}{H}$$

Hence,

$$H = \frac{0.3k(T_1 - T_2)}{q'} = \frac{0.3\text{m}(62.7 \text{ W/m}\cdot\text{K})(100^\circ\text{C})}{7800 \text{ W/m}} = 0.24\text{m.}$$

COMMENTS: The fact that $H < 0.3\text{m}$ is consistent with the requirement that the thermal resistance of the trapezoidal column must be less than that of a rectangular bar of the same height and top width (because the width of the trapezoidal column increases with increasing distance, x , from the top). Hence, if the rectangular bar is to be of equivalent resistance, it must be of smaller height.

PROBLEM 4S.7

KNOWN: Hollow prismatic bars fabricated from plain carbon steel, 1m in length with prescribed temperature difference.

FIND: Shape factors and heat rate per unit length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

PROPERTIES: Table A-1, Steel, Plain Carbon (400K), $k = 57 \text{ W/m}\cdot\text{K}$.

ANALYSIS: Construct a flux plot on the symmetrical sections (shaded-regions) of each of the bars.

The shape factors for the symmetrical sections are,

$$S_{o,A} = \frac{M\ell}{N} = \frac{4}{4}\ell = 1\ell \quad S_{o,B} = \frac{M\ell}{N} = \frac{3.5}{4}\ell = 0.88\ell.$$

Since each of these sections is $\frac{1}{4}$ of the bar cross-section, it follows that

$$S_A = 4 \times 1\ell = 4\ell \quad S_B = 4 \times 0.88\ell = 3.5\ell.$$

The heat rate per unit length is $q' = q/\ell = k(S/\ell)(T_1 - T_2)$,

$$q'_A = 57 \frac{\text{W}}{\text{m}\cdot\text{K}} \times 4(500 - 300) \text{ K} = 45.6 \text{ kW/m}$$

$$q'_B = 57 \frac{\text{W}}{\text{m}\cdot\text{K}} \times 3.5(500 - 300) \text{ K} = 39.9 \text{ kW/m}.$$

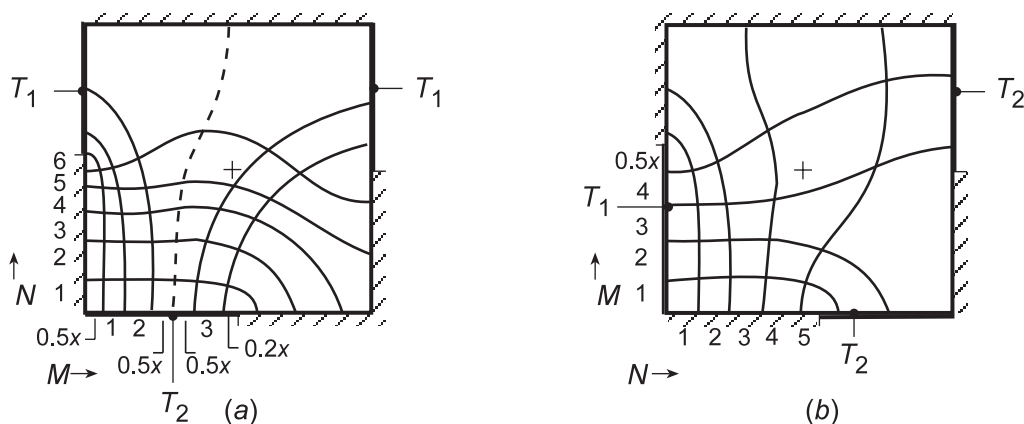

PROBLEM 4S.8

KNOWN: Two-dimensional, square shapes, 1 m to a side, maintained at uniform temperatures as prescribed, perfectly insulated elsewhere.

FIND: Using the flux plot method, estimate the heat rate per unit length normal to the page if the thermal conductivity is 50 W/m·K

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: Use the methodology of Section 4S.1 to construct the flux plots to obtain the shape factors from which the heat rates can be calculated. With Figure (a), begin at the lower-left side making the isotherms almost equally spaced, since the heat flow will only slightly spread toward the right. Start sketching the adiabats in the vicinity of the T_2 surface. The dashed line represents the adiabat which separates the shape into two segments. Having recognized this feature, it was convenient to identify partial heat lanes. Figure (b) is less difficult to analyze since the isotherm intervals are nearly regular in the lower left-hand corner.

The shape factors are calculated from Equation 4S.7 and the heat rate from Equation 4S.6.

$$S' = \frac{M}{N} = \frac{0.5 + 3 + 0.5 + 0.5 + 0.2}{6}$$

$$S' = \frac{M}{N} = \frac{4.5}{5} = 0.90$$

$$S' = 0.70$$

$$q' = kS'(T_1 - T_2)$$

$$q' = kS'(T_1 - T_2)$$

$$q' = 50 \text{ W/m} \cdot \text{K} \times 0.70(100 - 0) \text{ K} = 3500 \text{ W/m} \quad q' = 50 \text{ W/m} \cdot \text{K} \times 0.90(100 - 0) \text{ K} = 4500 \text{ W/m} \quad <$$

COMMENTS: Using a finite-element package with a fine mesh, we determined heat rates of 4780 and 4575 W/m, respectively, for Figures (a) and (b). The estimate for the less difficult Figure (b) is within 2% of the numerical method result. For Figure (a), our flux plot result was 27% low.

PROBLEM 5.1

KNOWN: Electrical heater attached to backside of plate while front surface is exposed to convection process (T_∞, h); initially plate is at a uniform temperature of the ambient air and suddenly heater power is switched on providing a constant q_0'' .

FIND: (a) Sketch temperature distribution, $T(x, t)$, (b) Sketch the heat flux at the outer surface, $q_x''(L, t)$ as a function of time.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible heat loss from heater through insulation.

ANALYSIS: (a) The temperature distributions for four time conditions including the initial distribution, $T(x, 0)$, and the steady-state distribution, $T(x, \infty)$, are as shown above.

Note that the temperature gradient at $x = 0$, $-dT/dx|_{x=0}$, for $t > 0$ will be a constant since the flux, $q_x''(0)$, is a constant. Noting that $T_0 = T(0, \infty)$, the steady-state temperature distribution will be linear such that

$$q_0'' = k \frac{T_0 - T(L, \infty)}{L} = h [T(L, \infty) - T_\infty].$$

(b) The heat flux at the front surface, $x = L$, is given by $q_x''(L, t) = -k(dT/dx)|_{x=L}$. From the temperature distribution, we can construct the heat flux-time plot.

COMMENTS: At early times, the temperature and heat flux at $x = L$ will not change from their initial values. Hence, we show a zero slope for $q_x''(L, t)$ at early times. Eventually, the value of $q_x''(L, t)$ will reach the steady-state value which is q_0'' .

PROBLEM 5.2

KNOWN: Plane wall whose inner surface is insulated and outer surface is exposed to an airstream at T_∞ . Initially, the wall is at a uniform temperature equal to that of the airstream. Suddenly, a radiant source is switched on applying a uniform flux, q_o'' , to the outer surface.

FIND: (a) Sketch temperature distribution on T - x coordinates for initial, steady-state, and two intermediate times, (b) Sketch heat flux at the outer surface, $q_x''(L,t)$, as a function of time.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal generation, $\dot{E}_g = 0$, (4) Surface at $x = 0$ is perfectly insulated, (5) All incident radiant power is absorbed and negligible radiation exchange with surroundings.

ANALYSIS: (a) The temperature distributions are shown on the T - x coordinates and labeled accordingly. Note these special features: (1) Gradient at $x = 0$ is always zero, (2) gradient is more steep at early times and (3) for steady-state conditions, the radiant flux is equal to the convective heat flux (this follows from an energy balance on the CS at $x = L$), $q_o'' = q_{\text{conv}}'' = h[T(L,\infty) - T_\infty]$.

(b) The heat flux at the outer surface, $q_x''(L,t)$, as a function of time appears as shown above.

COMMENTS: The sketches must reflect the initial and boundary conditions:

$T(x,0) = T_\infty$	uniform initial temperature.
$-k \frac{\partial T}{\partial x} \Big _{x=0} = 0$	insulated at $x = 0$.
$-k \frac{\partial T}{\partial x} \Big _{x=L} = h[T(L,t) - T_\infty] - q_o''$	surface energy balance at $x = L$.

PROBLEM 5.3

KNOWN: Microwave and radiant heating conditions for a slab of beef.

FIND: Sketch temperature distributions at specific times during heating and cooling.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x , (2) Uniform internal heat generation for microwave, (3) Uniform surface heating for radiant oven, (4) Heat loss from surface of meat to surroundings is negligible during the heating process, (5) Symmetry about midplane.

ANALYSIS:

COMMENTS: (1) With uniform generation and negligible surface heat loss, the temperature distribution remains nearly uniform during *microwave heating*. During the subsequent surface cooling, the maximum temperature is at the midplane.

(2) The interior of the meat is heated by conduction from the hotter surfaces during *radiant heating*, and the lowest temperature is at the midplane. The situation is reversed shortly after cooling begins, and the maximum temperature is at the midplane.

PROBLEM 5.4

KNOWN: Plate initially at a uniform temperature T_i is suddenly subjected to convection process (T_∞, h) on both surfaces. After elapsed time t_0 , plate is insulated on both surfaces.

FIND: (a) Assuming $Bi \gg 1$, sketch on $T - x$ coordinates: initial and steady-state ($t \rightarrow \infty$) temperature distributions, $T(x, t_0)$ and distributions for two intermediate times $t_0 < t < \infty$, (b) Sketch on $T - t$ coordinates midplane and surface temperature histories, (c) Repeat parts (a) and (b) assuming $Bi \ll 1$, and (d) Obtain expression for $T(x, \infty) = T_f$ in terms of plate parameters (M, c_p), thermal conditions (T_i, T_∞, h), surface temperature $T(L, t)$ and heating time t_0 .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal generation, (4) Plate is perfectly insulated for $t > t_0$, (5) $T(0, t < t_0) < T_\infty$.

ANALYSIS: (a,b) With $Bi \gg 1$, appreciable temperature gradients exist in the plate following exposure to the heating process.

On $T - x$ coordinates: (1) initial, uniform temperature, (2) steady-state conditions when $t \rightarrow \infty$, (3) distribution at t_0 just before plate is covered with insulation, (4) gradients are always zero (symmetry), and (5) when $t > t_0$ (dashed lines) gradients approach zero everywhere.

(c) If $Bi \ll 1$, plate is space-wise isothermal (no gradients). On $T - x$ coordinates, the temperature distributions are flat; on $T - t$ coordinates, $T(L, t) = T(0, t)$.

(d) The conservation of energy requirement for the interval of time $\Delta t = t_0$ is

$$E_{\text{in}} - E_{\text{out}} = \Delta E = E_{\text{final}} - E_{\text{initial}} \quad 2 \int_0^{t_0} h A_s [T_\infty - T(L, t)] dt - 0 = M c_p (T_f - T_i)$$

where E_{in} is due to convection heating over the period of time $t = 0 \rightarrow t_0$. With knowledge of $T(L, t)$, this expression can be integrated and a value for T_f determined.

PROBLEM 5.5

KNOWN: Diameter and initial temperature of steel balls cooling in air.

FIND: Time required to cool to a prescribed temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible radiation effects, (2) Constant properties.

ANALYSIS: Applying Eq. 5.10 to a sphere ($L_c = r_o/3$),

$$\text{Bi} = \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{20\text{ W/m}^2\cdot\text{K} (0.002\text{m})}{40\text{ W/m}\cdot\text{K}} = 0.001.$$

Hence, the temperature of the steel remains approximately uniform during the cooling process, and the lumped capacitance method may be used. From Eqs. 5.4 and 5.5,

$$t = \frac{\rho V c_p}{h A_s} \ln \frac{T_i - T_{\infty}}{T - T_{\infty}} = \frac{\rho (\pi D^3 / 6) c_p}{h \pi D^2} \ln \frac{T_i - T_{\infty}}{T - T_{\infty}}$$

$$t = \frac{7800\text{kg/m}^3 (0.012\text{m}) 600\text{J/kg}\cdot\text{K}}{6 \times 20\text{ W/m}^2\cdot\text{K}} \ln \frac{1150 - 325}{400 - 325}$$

$$t = 1122\text{ s} = 0.312\text{h}$$

<

COMMENTS: Due to the large value of T_i , radiation effects are likely to be significant during the early portion of the transient. The effect is to shorten the cooling time.

PROBLEM 5.6

KNOWN: Diameter and initial temperature of steel balls in air. Expression for the air temperature versus time.

FIND: (a) Expression for the sphere temperature, $T(t)$, (b) Graph of $T(t)$ and explanation of special features.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation heat transfer.

PROPERTIES: Given: $k = 40 \text{ W/m}\cdot\text{K}$, $\rho = 7800 \text{ kg/m}^3$, $c = 600 \text{ J/kg}\cdot\text{K}$.

ANALYSIS:

(a) Applying Equation 5.10 to a sphere ($L_c = r_o/3$),

$$B_i = \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{20 \text{ W/m}^2 \cdot \text{K} (0.002 \text{ m})}{40 \text{ W/m} \cdot \text{K}} = 0.001$$

Hence, the temperature of the steel sphere remains approximately uniform during the cooling process. Equation 5.2 is written, with $T_{\infty} = T_o + at$, as

$$-hA_s(T - T_o - at) = \rho \forall c \frac{dT}{dt}$$

Letting $\theta = T - T_o$, $dT = d\theta$ and $-hA_s(\theta - at) = \rho \forall c \frac{d\theta}{dt}$ or $\frac{d\theta}{dt} = -C(\theta - at)$ where $C = \frac{hA_s}{\rho \forall c}$

The solution may be written as the sum of the homogeneous and particular solutions,

$$\theta = \theta_h + \theta_p \quad \text{where} \quad \theta_h = c_1 \exp(-Ct).$$

Assuming $\theta_p = f(t)\theta_h$, we substitute into the differential equation to find

$$\frac{df}{dt} = Cat \exp(Ct)/c_1 \text{ from which } f = a(t - 1/C) \exp(Ct)/c_1.$$

Thus, the complete solution is

$$\theta = c_1 \exp(-Ct) + a(t - 1/C) \text{ and applying the initial condition we find}$$

$$T = (T_i - T_o + a/C) \exp(-Ct) + a(t - 1/C) + T_o$$

<

Continued...

PROBLEM 5.6 (Cont.)

(b) The ambient and sphere temperatures for $0 \leq t \leq 3600$ s are shown in the plot below.

Note that:

- (1) For small times ($t \leq 600$ s) the sphere temperature decreases rapidly,
- (2) at $t \approx 1100$ s, $T = T_{\infty}$ and, from Equation 5.2, $dT/dt = 0$,
- (3) at $t \geq 1100$ s, $T < T_{\infty}$,
- (4) at large time, $T - T_{\infty}$ and dT/dt are constant.

COMMENTS: Unless the air environment of Problem 5.5 is cooled, the air temperature will increase in temperature as energy is transferred from the balls. However, the actual air temperature versus time may not be linear.

PROBLEM 5.7

KNOWN: The temperature-time history of a pure copper sphere in an air stream.

FIND: The heat transfer coefficient between the sphere and the air stream.

SCHEMATIC:

ASSUMPTIONS: (1) Temperature of sphere is spatially uniform, (2) Negligible radiation exchange, (3) Constant properties.

PROPERTIES: Table A-1, Pure copper (333K): $\rho = 8933 \text{ kg/m}^3$, $c_p = 389 \text{ J/kg}\cdot\text{K}$, $k = 398 \text{ W/m}\cdot\text{K}$.

ANALYSIS: The time-temperature history is given by Eq. 5.6 with Eq. 5.7.

$$\frac{\theta(t)}{\theta_i} = \exp\left(-\frac{t}{R_t C_t}\right) \quad \text{where} \quad R_t = \frac{1}{hA_s} \quad A_s = \pi D^2$$

$$C_t = \rho V c_p \quad V = \frac{\pi D^3}{6}$$

$$\theta = T - T_\infty.$$

Recognize that when $t = 69\text{s}$,

$$\frac{\theta(t)}{\theta_i} = \frac{(55 - 27)^\circ\text{C}}{(66 - 27)^\circ\text{C}} = 0.718 = \exp\left(-\frac{t}{\tau_t}\right) = \exp\left(-\frac{69\text{s}}{\tau_t}\right)$$

and solving for τ_t find

$$\tau_t = 208\text{s}.$$

Hence,

$$h = \frac{\rho V c_p}{A_s \tau_t} = \frac{8933 \text{ kg/m}^3 \left(\pi (0.0127)^3 \text{ m}^3 / 6 \right) 389 \text{ J/kg}\cdot\text{K}}{\pi (0.0127)^2 \text{ m}^2 \times 208\text{s}}$$

$$h = 35.3 \text{ W/m}^2 \cdot \text{K}.$$

<

COMMENTS: Note that with $L_c = D_o/6$,

$$Bi = \frac{hL_c}{k} = 35.3 \text{ W/m}^2 \cdot \text{K} \times \frac{0.0127}{6} \text{ m} / 398 \text{ W/m}\cdot\text{K} = 1.88 \times 10^{-4}.$$

Hence, $Bi < 0.1$ and the spatially isothermal assumption is reasonable.

PROBLEM 5.8

KNOWN: Solid steel sphere (AISI 1010), coated with dielectric layer of prescribed thickness and thermal conductivity. Coated sphere, initially at uniform temperature, is suddenly quenched in an oil bath.

FIND: Time required for sphere to reach 140°C.

SCHEMATIC:

PROPERTIES: Table A-1, AISI 1010 Steel $\left(\bar{T} = [500 + 140]^\circ\text{C}/2 = 320^\circ\text{C} \approx 600\text{K}\right)$:

$$\rho = 7832\text{ kg/m}^3, \quad c = 559\text{ J/kg}\cdot\text{K}, \quad k = 48.8\text{ W/m}\cdot\text{K}.$$

ASSUMPTIONS: (1) Steel sphere is space-wise isothermal, (2) Dielectric layer has negligible thermal capacitance compared to steel sphere, (3) Layer is thin compared to radius of sphere, (4) Constant properties, (5) Neglect contact resistance between steel and coating.

ANALYSIS: The thermal resistance to heat transfer from the sphere is due to the dielectric layer and the convection coefficient. That is,

$$R'' = \frac{\ell}{k} + \frac{1}{h} = \frac{0.002\text{ m}}{0.04\text{ W/m}\cdot\text{K}} + \frac{1}{3300\text{ W/m}^2\cdot\text{K}} = (0.050 + 0.0003) = 0.0503 \frac{\text{m}^2\cdot\text{K}}{\text{W}},$$

or in terms of an overall coefficient, $U = 1/R'' = 19.88\text{ W/m}^2\cdot\text{K}$. The effective Biot number is

$$\text{Bi}_e = \frac{UL_c}{k} = \frac{U(r_o/3)}{k} = \frac{19.88\text{ W/m}^2\cdot\text{K} \times (0.300/6)\text{ m}}{48.8\text{ W/m}\cdot\text{K}} = 0.0204$$

where the characteristic length is $L_c = r_o/3$ for the sphere. Since $\text{Bi}_e < 0.1$, the lumped capacitance approach is applicable. Hence, Eq. 5.5 is appropriate with h replaced by U ,

$$t = \frac{\rho c}{U} \left[\frac{V}{A_s} \right] \ln \frac{\theta_1}{\theta_0} = \frac{\rho c}{U} \left[\frac{V}{A_s} \right] \ln \frac{T(0) - T_\infty}{T(t) - T_\infty}.$$

Substituting numerical values with $(V/A_s) = r_o/3 = D/6$,

$$t = \frac{7832\text{ kg/m}^3 \times 559\text{ J/kg}\cdot\text{K}}{19.88\text{ W/m}^2\cdot\text{K}} \left[\frac{0.300\text{ m}}{6} \right] \ln \frac{(500 - 100)^\circ\text{C}}{(140 - 100)^\circ\text{C}}$$

$$t = 25,358\text{ s} = 7.04\text{ h}.$$

<

COMMENTS: (1) Note from calculation of R'' that the resistance of the dielectric layer dominates and therefore nearly all the temperature drop occurs across the layer.

PROBLEM 5.9

KNOWN: Thickness, surface area, and properties of iron base plate. Heat flux at inner surface. Temperature of surroundings. Temperature and convection coefficient of air at outer surface.

FIND: Time required for plate to reach a temperature of 135°C. Operating efficiency of iron.

SCHEMATIC:

ASSUMPTIONS: (1) Radiation exchange is between a small surface and large surroundings, (2) Convection coefficient is independent of time, (3) Constant properties, (4) Iron is initially at room temperature ($T_i = T_\infty$).

ANALYSIS: Biot numbers may be based on convection heat transfer and/or the maximum heat transfer by radiation, which would occur when the plate reaches the desired temperature ($T = 135^\circ\text{C}$).

From Eq. (1.9) the corresponding radiation transfer coefficient is $h_r = \epsilon\sigma(T + T_{\text{sur}})(T^2 + T_{\text{sur}}^2) = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (408 + 298) \text{ K} (408^2 + 298^2) \text{ K}^2 = 8.2 \text{ W/m}^2 \cdot \text{K}$. Hence,

$$\text{Bi} = \frac{hL}{k} = \frac{10 \text{ W/m}^2 \cdot \text{K} (0.007 \text{ m})}{180 \text{ W/m} \cdot \text{K}} = 3.9 \times 10^{-4}$$

$$\text{Bi}_r = \frac{h_r L}{k} = \frac{8.2 \text{ W/m}^2 \cdot \text{K} (0.007 \text{ m})}{180 \text{ W/m} \cdot \text{K}} = 3.2 \times 10^{-4}$$

With convection and radiation considered independently or collectively, Bi , Bi_r , $\text{Bi} + \text{Bi}_r \ll 1$ and the lumped capacitance analysis may be used.

The energy balance, Eq. (5.15), associated with Figure 5.5 may be applied to this problem. With $\dot{E}_g = 0$, the integral form of the equation is

$$T - T_i = \frac{A_s}{\rho V c} \int_0^t \left[q_h'' - h(T - T_\infty) - \epsilon\sigma(T^4 - T_{\text{sur}}^4) \right] dt$$

Integrating numerically, we obtain, for $T = 135^\circ\text{C}$,

$$t = 168 \text{ s}$$

<

COMMENTS: Note that, if heat transfer is by natural convection, h , like h_r , will vary during the process from a value of 0 at $t = 0$ to a maximum at $t = 168 \text{ s}$.

PROBLEM 5.10

KNOWN: Diameter and radial temperature of AISI 1010 carbon steel shaft. Convection coefficient and temperature of furnace gases.

FIND: Time required for shaft centerline to reach a prescribed temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Constant properties.

PROPERTIES: AISI 1010 carbon steel, Table A.1 ($\bar{T} = 550 \text{ K}$): $\rho = 7832 \text{ kg/m}^3$, $k = 51.2 \text{ W/m} \cdot \text{K}$, $c = 541 \text{ J/kg} \cdot \text{K}$, $\alpha = 1.21 \times 10^{-5} \text{ m}^2/\text{s}$.

ANALYSIS: The Biot number is

$$\text{Bi} = \frac{hr_o/2}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} (0.05 \text{ m}/2)}{51.2 \text{ W/m} \cdot \text{K}} = 0.0488.$$

Hence, the lumped capacitance method can be applied. From Equation 5.6,

$$\begin{aligned} \frac{T - T_\infty}{T_i - T_\infty} &= \exp \left[- \left(\frac{hAs}{\rho Vc} \right) t \right] = \exp \left[- \frac{4h}{\rho cD} t \right] \\ \ln \left(\frac{800 - 1200}{300 - 1200} \right) &= -0.811 = - \frac{4 \times 100 \text{ W/m}^2 \cdot \text{K}}{7832 \text{ kg/m}^3 (541 \text{ J/kg} \cdot \text{K}) 0.1 \text{ m}} t \\ t &= 859 \text{ s.} \end{aligned}$$

COMMENTS: To check the validity of the foregoing result, use the one-term approximation to the series solution. From Equation 5.49c,

$$\frac{T_o - T_\infty}{T_i - T_\infty} = \frac{-400}{-900} = 0.444 = C_1 \exp(-\zeta_1^2 \text{Fo})$$

For $\text{Bi} = hr_o/k = 0.0976$, Table 5.1 yields $\zeta_1 = 0.436$ and $C_1 = 1.024$. Hence

$$\begin{aligned} \frac{-(0.436)^2 (1.2 \times 10^{-5} \text{ m}^2/\text{s})}{(0.05 \text{ m})^2} t &= \ln(0.434) = -0.835 \\ t &= 915 \text{ s.} \end{aligned}$$

The results agree to within 6%. The lumped capacitance method underestimates the actual time, since the response at the centerline lags that at any other location in the shaft.

PROBLEM 5.11

KNOWN: Configuration, initial temperature and charging conditions of a thermal energy storage unit.

FIND: Time required to achieve 75% of maximum possible energy storage. Temperature of storage medium at this time.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible radiation exchange with surroundings.

PROPERTIES: Table A-1, Aluminum, pure ($\bar{T} \approx 600\text{K} = 327^\circ\text{C}$): $k = 231\text{ W/m}\cdot\text{K}$, $c = 1033\text{ J/kg}\cdot\text{K}$, $\rho = 2702\text{ kg/m}^3$.

ANALYSIS: Recognizing the characteristic length is the half thickness, find

$$Bi = \frac{hL}{k} = \frac{100\text{ W/m}^2\cdot\text{K} \times 0.025\text{ m}}{231\text{ W/m}\cdot\text{K}} = 0.011.$$

Hence, the lumped capacitance method may be used. From Eq. 5.8,

$$Q = (\rho V c) \theta_i [1 - \exp(-t/\tau_t)] = -\Delta E_{st} \quad (1)$$

$$-\Delta E_{st, \max} = (\rho V c) \theta_i. \quad (2)$$

Dividing Eq. (1) by (2),

$$\Delta E_{st} / \Delta E_{st, \max} = 1 - \exp(-t/\tau_{th}) = 0.75.$$

$$\text{Solving for } \tau_{th} = \frac{\rho V c}{h A_s} = \frac{\rho L c}{h} = \frac{2702\text{ kg/m}^3 \times 0.025\text{ m} \times 1033\text{ J/kg}\cdot\text{K}}{100\text{ W/m}^2\cdot\text{K}} = 698\text{ s}.$$

Hence, the required time is

$$-\exp(-t/698\text{ s}) = -0.25 \quad \text{or} \quad t = 968\text{ s}. \quad <$$

From Eq. 5.6,

$$\frac{T - T_\infty}{T_i - T_\infty} = \exp(-t/\tau_{th})$$

$$T = T_\infty + (T_i - T_\infty) \exp(-t/\tau_{th}) = 600^\circ\text{C} - (575^\circ\text{C}) \exp(-968/698)$$

$$T = 456^\circ\text{C}. \quad <$$

COMMENTS: For the prescribed temperatures, the property temperature dependence is significant and some error is incurred by assuming constant properties. However, selecting properties at 600K was reasonable for this estimate.

PROBLEM 5.12

KNOWN: Diameter, density, specific heat and thermal conductivity of aluminum spheres used in packed bed thermal energy storage system. Convection coefficient and inlet gas temperature.

FIND: Time required for sphere to acquire 90% of maximum possible thermal energy and the corresponding center temperature. Potential advantage of using copper in lieu of aluminum.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat transfer to or from a sphere by radiation or conduction due to contact with other spheres, (2) Constant properties.

ANALYSIS: To determine whether a lumped capacitance analysis can be used, first compute $Bi = h(r_o/3)/k = 75 \text{ W/m}^2 \cdot \text{K} (0.025\text{m})/240 \text{ W/m} \cdot \text{K} = 0.0078 < 0.1$. Hence, the lumped capacitance approximation may be made, and a uniform temperature may be assumed to exist in the sphere at any time. From Eq. 5.8a, achievement of 90% of the maximum possible thermal energy storage corresponds to

$$\frac{Q}{\rho c V \theta_i} = 0.90 = 1 - \exp(-t / \tau_t)$$

where $\tau_t = \rho V c / h A_s = \rho D c / 6h = 2700 \text{ kg/m}^3 \times 0.075\text{m} \times 950 \text{ J/kg} \cdot \text{K} / 6 \times 75 \text{ W/m}^2 \cdot \text{K} = 427\text{s}$. Hence,

$$t = -\tau_t \ln(0.1) = 427\text{s} \times 2.30 = 984\text{s} \quad <$$

From Eq. (5.6), the corresponding temperature at any location in the sphere is

$$T(984\text{s}) = T_{g,i} + (T_i - T_{g,i}) \exp(-6ht / \rho D c)$$

$$T(984\text{s}) = 300^\circ\text{C} - 275^\circ\text{C} \exp\left(-6 \times 75 \text{ W/m}^2 \cdot \text{K} \times 984\text{s} / 2700 \text{ kg/m}^3 \times 0.075\text{m} \times 950 \text{ J/kg} \cdot \text{K}\right)$$

$$T(984\text{s}) = 272.5^\circ\text{C} \quad <$$

Obtaining the density and specific heat of copper from Table A-1, we see that $(\rho c)_{\text{Cu}} \approx 8900 \text{ kg/m}^3 \times 400 \text{ J/kg} \cdot \text{K} = 3.56 \times 10^6 \text{ J/m}^3 \cdot \text{K} > (\rho c)_{\text{Al}} = 2.57 \times 10^6 \text{ J/m}^3 \cdot \text{K}$. Hence, for an equivalent sphere diameter, the copper can store approximately 38% more thermal energy than the aluminum.

COMMENTS: Before the packed bed becomes fully charged, the temperature of the gas decreases as it passes through the bed. Hence, the time required for a sphere to reach a prescribed state of thermal energy storage increases with increasing distance from the bed inlet.

PROBLEM 5.13

KNOWN: Wafer, initially at 100°C, is suddenly placed on a chuck with uniform and constant temperature, 23°C. Wafer temperature after 15 seconds is observed as 33°C.

FIND: (a) Contact resistance, R''_{tc} , between interface of wafer and chuck through which helium slowly flows, and (b) Whether R''_{tc} will change if air, rather than helium, is the purge gas.

SCHEMATIC:

PROPERTIES: Wafer (silicon, typical values): $\rho = 2700 \text{ kg/m}^3$, $c = 875 \text{ J/kg}\cdot\text{K}$, $k = 177 \text{ W/m}\cdot\text{K}$.

ASSUMPTIONS: (1) Wafer behaves as a space-wise isothermal object, (2) Negligible heat transfer from wafer top surface, (3) Chuck remains at uniform temperature, (4) Thermal resistance across the interface is due to conduction effects, not convective, (5) Constant properties.

ANALYSIS: (a) Perform an energy balance on the wafer as shown in the Schematic.

$$\dot{E}''_{in} - \dot{E}''_{out} + \dot{E}_g = \dot{E}_{st} \quad (1)$$

$$-q''_{cond} = \dot{E}_{st} \quad (2)$$

$$-\frac{T_w(t) - T_c}{R''_{tc}} = \rho w c \frac{dT_w}{dt} \quad (3)$$

Separate and integrate Eq. (3)

$$-\int_0^t \frac{dt}{\rho w c R''_{tc}} = \int_{T_{wi}}^{T_w} \frac{dT_w}{T_w - T_c} \quad (4) \quad \frac{T_w(t) - T_c}{T_{wi} - T_c} = \exp\left[-\frac{t}{\rho w c R''_{tc}}\right] \quad (5)$$

Substituting numerical values for $T_w(15s) = 33^\circ\text{C}$,

$$\frac{(33 - 23)^\circ\text{C}}{(100 - 23)^\circ\text{C}} = \exp\left[-\frac{15s}{2700 \text{ kg/m}^3 \times 0.758 \times 10^{-3} \text{ m} \times 875 \text{ J/kg}\cdot\text{K} \times R''_{tc}}\right] \quad (6)$$

$$R''_{tc} = 0.0041 \text{ m}^2 \cdot \text{K/W} \quad <$$

(b) R''_{tc} will increase since $k_{air} < k_{helium}$. See Table A.4.

COMMENTS: Note that $Bi = R_{int}/R_{ext} = (w/k)/R''_{tc} = 0.001$. Hence the spacewise isothermal assumption is reasonable.

PROBLEM 5.14

KNOWN: Inner diameter and wall thickness of a spherical, stainless steel vessel. Initial temperature, density, specific heat and heat generation rate of reactants in vessel. Convection conditions at outer surface of vessel.

FIND: (a) Temperature of reactants after one hour of reaction time, (b) Effect of convection coefficient on thermal response of reactants.

SCHEMATIC:

ASSUMPTIONS: (1) Temperature of well stirred reactants is uniform at any time and is equal to inner surface temperature of vessel ($T = T_{s,i}$), (2) Thermal capacitance of vessel may be neglected, (3) Negligible radiation exchange with surroundings, (4) Constant properties.

ANALYSIS: (a) Transient thermal conditions within the reactor may be determined from Eq. (5.25), which reduces to the following form for $T_i - T_\infty = 0$.

$$T = T_\infty + (b/a) [1 - \exp(-at)]$$

where $a = UA/\rho Vc$ and $b = \dot{E}_g / \rho Vc = \dot{q} / \rho c$. From Eq. (3.19) the product of the overall heat transfer coefficient and the surface area is $UA = (R_{\text{cond}} + R_{\text{conv}})^{-1}$, where from Eqs. (3.36) and (3.9),

$$R_{t,\text{cond}} = \frac{1}{2\pi k} \left(\frac{1}{D_i} - \frac{1}{D_o} \right) = \frac{1}{2\pi (17 \text{ W/m} \cdot \text{K})} \left(\frac{1}{1.0 \text{ m}} - \frac{1}{1.1 \text{ m}} \right) = 8.51 \times 10^{-4} \text{ K/W}$$

$$R_{t,\text{conv}} = \frac{1}{hA_o} = \frac{1}{(6 \text{ W/m}^2 \cdot \text{K}) \pi (1.1 \text{ m})^2} = 0.0438 \text{ K/W}$$

Hence, $UA = 22.4 \text{ W/K}$. It follows that, with $V = \pi D_i^3 / 6$,

$$a = \frac{UA}{\rho Vc} = \frac{6(22.4 \text{ W/K})}{1100 \text{ kg/m}^3 \times \pi (1 \text{ m})^3 \times 2400 \text{ J/kg} \cdot \text{K}} = 1.620 \times 10^{-5} \text{ s}^{-1}$$

$$b = \frac{\dot{q}}{\rho c} = \frac{10^4 \text{ W/m}^3}{1100 \text{ kg/m}^3 \times 2400 \text{ J/kg} \cdot \text{K}} = 3.788 \times 10^{-3} \text{ K/s}$$

With $(b/a) = 233.8^\circ\text{C}$ and $t = 18,000 \text{ s}$,

$$T = 25^\circ\text{C} + 233.8^\circ\text{C} \left[1 - \exp\left(-1.62 \times 10^{-5} \text{ s}^{-1} \times 18,000 \text{ s}\right) \right] = 84.1^\circ\text{C} \quad <$$

Neglecting the thermal capacitance of the vessel wall, the heat rate by conduction through the wall is equal to the heat transfer by convection from the outer surface, and from the thermal circuit, we know that

PROBLEM 5.14 (Cont.)

$$\frac{T - T_{s,o}}{T_{s,o} - T_{\infty}} = \frac{R_{t,cond}}{R_{t,conv}} = \frac{8.51 \times 10^{-4} \text{ K/W}}{0.0438 \text{ K/W}} = 0.0194$$

$$T_{s,o} = \frac{T + 0.0194 T_{\infty}}{1.0194} = \frac{84.1^{\circ}\text{C} + 0.0194(25^{\circ}\text{C})}{1.0194} = 83.0^{\circ}\text{C}$$

<

(b) Representative low and high values of h could correspond to $2 \text{ W/m}^2 \cdot \text{K}$ and $100 \text{ W/m}^2 \cdot \text{K}$ for free and forced convection, respectively. Calculations based on Eq. (5.25) yield the following temperature histories.

Forced convection is clearly an effective means of reducing the temperature of the reactants and accelerating the approach to steady-state conditions.

COMMENTS: The validity of neglecting thermal energy storage effects for the vessel may be assessed by contrasting its thermal capacitance with that of the reactants. Selecting values of $\rho = 8000 \text{ kg/m}^3$ and $c = 475 \text{ J/kg} \cdot \text{K}$ for stainless steel from Table A-1, the thermal capacitance of the vessel is $C_{t,v} = (\rho V c)_{st} = 6.57 \times 10^5 \text{ J/K}$, where $V = (\pi/6)(D_o^3 - D_i^3)$. With $C_{t,r} = (\rho V c)_r = 2.64 \times 10^6 \text{ J/K}$ for the reactants, $C_{t,r}/C_{t,v} \approx 4$. Hence, the capacitance of the vessel is not negligible and should be considered in a more refined analysis of the problem.

PROBLEM 5.15

KNOWN: Volume, density and specific heat of chemical in a stirred reactor. Temperature and convection coefficient associated with saturated steam flowing through submerged coil. Tube diameter and outer convection coefficient of coil. Initial and final temperatures of chemical and time span of heating process.

FIND: Required length of submerged tubing. Minimum allowable steam flowrate.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible heat loss from vessel to surroundings, (3) Chemical is isothermal, (4) Negligible work due to stirring, (5) Negligible thermal energy generation (or absorption) due to chemical reactions associated with the batch process, (6) Negligible tube wall conduction resistance, (7) Negligible kinetic energy, potential energy, and flow work changes for steam.

ANALYSIS: Heating of the chemical can be treated as a transient, lumped capacitance problem, wherein heat transfer from the coil is balanced by the increase in thermal energy of the chemical. Hence, conservation of energy yields

$$\frac{dU}{dt} = \rho V c \frac{dT}{dt} = U A_s (T_h - T)$$

Integrating, $\int_{T_i}^T \frac{dT}{T_h - T} = \frac{U A_s}{\rho V c} \int_0^t dt$

$$-\ln \frac{T_h - T}{T_h - T_i} = \frac{U A_s t}{\rho V c}$$

$$A_s = -\frac{\rho V c}{U t} \ln \frac{T_h - T}{T_h - T_i} \quad (1)$$

$$U = \left(h_i^{-1} + h_o^{-1} \right)^{-1} = \left[(1/10,000) + (1/2000) \right]^{-1} \text{ W/m}^2 \cdot \text{K}$$

$$U = 1670 \text{ W/m}^2 \cdot \text{K}$$

$$A_s = -\frac{\left(1200 \text{ kg/m}^3 \right) \left(2.25 \text{ m}^3 \right) \left(2200 \text{ J/kg} \cdot \text{K} \right)}{\left(1670 \text{ W/m}^2 \cdot \text{K} \right) \left(3600 \text{ s} \right)} \ln \frac{500 - 450}{500 - 300} = 1.37 \text{ m}^2$$

$$L = \frac{A_s}{\pi D} = \frac{1.37 \text{ m}^2}{\pi (0.02 \text{ m})} = 21.8 \text{ m}$$

<

COMMENTS: Eq. (1) could also have been obtained by adapting Eq. (5.5) to the conditions of this problem, with T_∞ and h replaced by T_h and U , respectively.

PROBLEM 5.16

KNOWN: Thickness and properties of furnace wall. Thermal resistance of film on surface of wall exposed to furnace gases. Initial wall temperature.

FIND: (a) Time required for surface of wall to reach a prescribed temperature, (b) Corresponding value of film surface temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible film thermal capacitance, (3) Negligible radiation.

PROPERTIES: Carbon steel (given): $\rho = 7850 \text{ kg/m}^3$, $c = 430 \text{ J/kg} \cdot \text{K}$, $k = 60 \text{ W/m} \cdot \text{K}$.

ANALYSIS: The overall coefficient for heat transfer from the surface of the steel to the gas is

$$U = (R''_{\text{tot}})^{-1} = \left(\frac{1}{h} + R''_f \right)^{-1} = \left(\frac{1}{25 \text{ W/m}^2 \cdot \text{K}} + 10^{-2} \text{ m}^2 \cdot \text{K/W} \right)^{-1} = 20 \text{ W/m}^2 \cdot \text{K}.$$

Hence,

$$\text{Bi} = \frac{UL}{k} = \frac{20 \text{ W/m}^2 \cdot \text{K} \times 0.01 \text{ m}}{60 \text{ W/m} \cdot \text{K}} = 0.0033$$

and the lumped capacitance method can be used.

(a) It follows that

$$\frac{T - T_{\infty}}{T_i - T_{\infty}} = \exp(-t/\tau_t) = \exp(-t/RC) = \exp(-Ut/\rho Lc)$$

$$t = -\frac{\rho Lc}{U} \ln \frac{T - T_{\infty}}{T_i - T_{\infty}} = -\frac{7850 \text{ kg/m}^3 (0.01 \text{ m}) 430 \text{ J/kg} \cdot \text{K}}{20 \text{ W/m}^2 \cdot \text{K}} \ln \frac{1200 - 1300}{300 - 1300}$$

$$t = 3886 \text{ s} = 1.08 \text{ h.}$$

<

(b) Performing an energy balance at the outer surface (s,o),

$$h(T_{\infty} - T_{s,o}) = (T_{s,o} - T_{s,i})/R''_f$$

$$T_{s,o} = \frac{hT_{\infty} + T_{s,i}/R''_f}{h + (1/R''_f)} = \frac{25 \text{ W/m}^2 \cdot \text{K} \times 1300 \text{ K} + 1200 \text{ K}/10^{-2} \text{ m}^2 \cdot \text{K/W}}{(25 + 100) \text{ W/m}^2 \cdot \text{K}}$$

$$T_{s,o} = 1220 \text{ K.}$$

<

COMMENTS: The film increases τ_t by increasing R_t but not C_t .

PROBLEM 5.17

KNOWN: Thickness and properties of strip steel heated in an annealing process. Furnace operating conditions.

FIND: (a) Time required to heat the strip from 300 to 600°C. Required furnace length for prescribed strip velocity ($V = 0.5$ m/s), (b) Effect of wall temperature on strip speed, temperature history, and radiation coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible temperature gradients in transverse direction across strip, (c) Negligible effect of strip conduction in longitudinal direction.

PROPERTIES: Steel: $\rho = 7900$ kg/m³, $c_p = 640$ J/kg·K, $k = 30$ W/m·K, $\varepsilon = 0.7$.

ANALYSIS: (a) Considering a fixed (control) mass of the moving strip, its temperature variation with time may be obtained from an energy balance which equates the change in energy storage to heat transfer by convection and radiation. If the surface area associated with one side of the control mass is designated as A_s , $A_{s,c} = A_{s,r} = 2A_s$ and $V = \delta A_s$ in Equation 5.15, which reduces to

$$\rho c \delta \frac{dT}{dt} = -2 \left[h(T - T_\infty) + \varepsilon \sigma (T^4 - T_{sur}^4) \right]$$

or, introducing the radiation coefficient from Equations 1.8 and 1.9 and integrating,

$$T_f - T_i = -\frac{1}{\rho c (\delta/2)} \int_{T_i}^{T_f} [h(T - T_\infty) + h_r(T - T_{sur})] dt$$

Using the IHT *Lumped Capacitance Model* to integrate numerically with $T_i = 573$ K, we find that $T_f = 873$ K corresponds to

$$t_f \approx 209 \text{ s} \quad \text{<}$$

in which case, the required furnace length is

$$L = V t_f \approx 0.5 \text{ m/s} \times 209 \text{ s} \approx 105 \text{ m} \quad \text{<}$$

(b) For $T_w = 1123$ K and 1273 K, the numerical integration yields $t_f \approx 102$ s and 62 s respectively. Hence, for $L = 105$ m, $V = L/t_f$ yields

$$V(T_w = 1123 \text{ K}) = 1.03 \text{ m/s}$$

$$V(T_w = 1273 \text{ K}) = 1.69 \text{ m/s} \quad \text{<}$$

Continued...

PROBLEM 5.17 (Cont.)

which correspond to increased process rates of 106% and 238%, respectively. Clearly, productivity can be enhanced by increasing the furnace environmental temperature, albeit at the expense of increasing energy utilization and operating costs.

If the annealing process extends from 25°C (298 K) to 600°C (873 K), numerical integration yields the following results for the prescribed furnace temperatures.

As expected, the heating rate and time, respectively, increase and decrease significantly with increasing T_w . Although the radiation heat transfer rate decreases with increasing time, the coefficient h_r increases with t as the strip temperature approaches T_w .

COMMENTS: To check the validity of the lumped capacitance approach, we calculate the Biot number based on a maximum cumulative coefficient of $(h + h_r) \approx 300 \text{ W/m}^2\cdot\text{K}$. It follows that $\text{Bi} = (h + h_r)(\delta/2)/k = 0.06$ and the assumption is valid.

PROBLEM 5.18

KNOWN: Diameter, resistance and current flow for a wire. Convection coefficient and temperature of surrounding oil.

FIND: Steady-state temperature of the wire. Time for the wire temperature to come within 1°C of its steady-state value.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Wire temperature is independent of x .

PROPERTIES: Wire (given): $\rho = 8000 \text{ kg/m}^3$, $c_p = 500 \text{ J/kg} \cdot \text{K}$, $k = 20 \text{ W/m} \cdot \text{K}$, $R'_e = 0.01 \Omega/\text{m}$.

ANALYSIS: Since

$$Bi = \frac{h(r_o/2)}{k} = \frac{500 \text{ W/m}^2 \cdot \text{K} (2.5 \times 10^{-4} \text{ m})}{20 \text{ W/m} \cdot \text{K}} = 0.006 < 0.1$$

the lumped capacitance method can be used. The problem has been analyzed in Example 1.3, and without radiation the steady-state temperature is given by

$$\pi Dh(T - T_\infty) = I^2 R'_e.$$

Hence

$$T = T_\infty + \frac{I^2 R'_e}{\pi Dh} = 25^\circ \text{C} + \frac{(100 \text{ A})^2 0.01 \Omega/\text{m}}{\pi (0.001 \text{ m}) 500 \text{ W/m}^2 \cdot \text{K}} = 88.7^\circ \text{C}. \quad <$$

With no radiation, the transient thermal response of the wire is governed by the expression (Example 1.3)

$$\frac{dT}{dt} = \frac{I^2 R'_e}{\rho c_p (\pi D^2/4)} - \frac{4h}{\rho c_p D} (T - T_\infty).$$

With $T = T_i = 25^\circ \text{C}$ at $t = 0$, the solution is

$$\frac{T - T_\infty - (I^2 R'_e / \pi Dh)}{T_i - T_\infty - (I^2 R'_e / \pi Dh)} = \exp\left(-\frac{4h}{\rho c_p D} t\right).$$

Substituting numerical values, find

$$\frac{88.7 - 25 - 63.7}{25 - 25 - 63.7} = \exp\left(-\frac{4 \times 500 \text{ W/m}^2 \cdot \text{K}}{8000 \text{ kg/m}^3 \times 500 \text{ J/kg} \cdot \text{K} \times 0.001 \text{ m}} t\right)$$

$$t = 8.31 \text{ s}. \quad <$$

COMMENTS: The time to reach steady state increases with increasing ρ , c_p and D and with decreasing h .

PROBLEM 5.19

KNOWN: Electrical heater attached to backside of plate while front is exposed to a convection process (T_∞, h); initially plate is at uniform temperature T_∞ before heater power is switched on.

FIND: (a) Expression for temperature of plate as a function of time assuming plate is spacewise isothermal, (b) Approximate time to reach steady-state and $T(\infty)$ for prescribed T_∞, h and q_o'' when wall material is pure copper, (c) Effect of h on thermal response.

SCHEMATIC:

ASSUMPTIONS: (1) Plate behaves as lumped capacitance, (2) Negligible loss out backside of heater, (3) Negligible radiation, (4) Constant properties.

PROPERTIES: Table A-1, Copper, pure (350 K): $k = 397 \text{ W/m}\cdot\text{K}$, $c_p = 385 \text{ J/kg}\cdot\text{K}$, $\rho = 8933 \text{ kg/m}^3$.

ANALYSIS: (a) Following the analysis of Section 5.3, the energy conservation requirement for the system is $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$ or $q_o'' - h(T - T_\infty) = \rho L c_p dT/dt$. Rearranging, and with $R_t'' = 1/h$ and $C_t'' = \rho L c_p$,

$$T - T_\infty - q_o''/h = -R_t'' \cdot C_t'' dT/dt \quad (1)$$

Defining $\theta(t) \equiv T - T_\infty - q_o''/h$ with $d\theta = dT$, the differential equation is

$$\theta = -R_t'' C_t'' \frac{d\theta}{dt} \quad (2)$$

Separating variables and integrating,

$$\int_{\theta_i}^{\theta} \frac{d\theta}{\theta} = - \int_0^t \frac{dt}{R_t'' C_t''}$$

it follows that

$$\frac{\theta}{\theta_i} = \exp\left(-\frac{t}{R_t'' C_t''}\right) \quad (3)$$

where $\theta_i = \theta(0) = T_i - T_\infty - (q_o''/h)$ (4)

(b) For $h = 50 \text{ W/m}^2 \cdot \text{K}$, the steady-state temperature can be determined from Eq. (3) with $t \rightarrow \infty$; that is,

$$\theta(\infty) = 0 = T(\infty) - T_\infty - q_o''/h \quad \text{or} \quad T(\infty) = T_\infty + q_o''/h,$$

giving $T(\infty) = 27^\circ\text{C} + 5000 \text{ W/m}^2 / 50 \text{ W/m}^2 \cdot \text{K} = 127^\circ\text{C}$. To estimate the time to reach steady-state, first determine the thermal time constant of the system,

$$\tau_t = R_t'' C_t'' = \left(\frac{1}{h}\right)(\rho c_p L) = \left(\frac{1}{50 \text{ W/m}^2 \cdot \text{K}}\right)(8933 \text{ kg/m}^3 \times 385 \text{ J/kg} \cdot \text{K} \times 12 \times 10^{-3} \text{ m}) = 825 \text{ s}$$

Continued...

PROBLEM 5.19 (Cont.)

When $t = 3\tau_t = 3 \times 825\text{s} = 2475\text{s}$, Eqs. (3) and (4) yield

$$\theta(3\tau_t) = T(3\tau_t) - 27^\circ\text{C} - \frac{5000\text{ W/m}^2}{50\text{ W/m}^2 \cdot \text{K}} = e^{-3} \left[27^\circ\text{C} - 27^\circ\text{C} - \frac{5000\text{ W/m}^2}{50\text{ W/m}^2 \cdot \text{K}} \right]$$

$$T(3\tau_t) = 122^\circ\text{C}$$

<

(c) As shown by the following graphical results, which were generated using the IHT *Lumped Capacitance Model*, the steady-state temperature and the time to reach steady-state both decrease with increasing h .

COMMENTS: Note that, even for $h = 200\text{ W/m}^2 \cdot \text{K}$, $\text{Bi} = hL/k \ll 0.1$ and assumption (1) is reasonable.

PROBLEM 5.20

KNOWN: Electronic device on aluminum, finned heat sink modeled as spatially isothermal object with internal generation and convection from its surface.

FIND: (a) Temperature response after device is energized, (b) Temperature rise for prescribed conditions after 5 min.

SCHEMATIC:

ASSUMPTIONS: (1) Spatially isothermal object, (2) Object is primarily aluminum, (3) Initially, object is in equilibrium with surroundings at T_∞ .

PROPERTIES: Table A-1, Aluminum, pure $\left(\bar{T} = (20 + 100)^\circ \text{C} / 2 \approx 333\text{K}\right)$: $c = 918 \text{ J/kg} \cdot \text{K}$.

ANALYSIS: (a) Following the general analysis of Section 5.3, apply the conservation of energy requirement to the object,

$$\dot{E}_{\text{in}} + \dot{E}_g - \dot{E}_{\text{out}} = \dot{E}_{\text{st}} \quad \dot{E}_g - \bar{h}A_s(T - T_\infty) = Mc \frac{dT}{dt} \quad (1)$$

where $T = T(t)$. Consider now steady-state conditions, in which case the storage term of Eq. (1) is zero. The temperature of the object will be $T(\infty)$ such that

$$\dot{E}_g = \bar{h}A_s(T(\infty) - T_\infty). \quad (2)$$

Substituting for \dot{E}_g using Eq. (2) into Eq. (1), the differential equation is

$$[T(\infty) - T_\infty] - [T - T_\infty] = \frac{Mc}{\bar{h}A_s} \frac{dT}{dt} \quad \text{or} \quad \theta = -\frac{Mc}{\bar{h}A_s} \frac{d\theta}{dt} \quad (3,4)$$

with $\theta \equiv T - T(\infty)$ and noting that $d\theta = dT$. Identifying $R_t = 1/\bar{h}A_s$ and $C_t = Mc$, the differential equation is integrated with proper limits,

$$\frac{1}{R_t C_t} \int_0^t dt = -\int_{\theta_i}^{\theta} \frac{d\theta}{\theta} \quad \text{or} \quad \frac{\theta}{\theta_i} = \exp\left[-\frac{t}{R_t C_t}\right] \quad (5) <$$

where $\theta_i = \theta(0) = T_i - T(\infty)$ and T_i is the initial temperature of the object.

(b) Using the information about steady-state conditions and Eq. (2), find first the thermal resistance and capacitance of the system,

$$R_t = \frac{1}{\bar{h}A_s} = \frac{T(\infty) - T_\infty}{\dot{E}_g} = \frac{(100 - 20)^\circ \text{C}}{60 \text{ W}} = 1.33 \text{ K/W} \quad C_t = Mc = 0.31 \text{ kg} \times 918 \text{ J/kg} \cdot \text{K} = 285 \text{ J/K}.$$

Using Eq. (5), the temperature of the system after 5 minutes is

$$\frac{\theta(5\text{min})}{\theta_i} = \frac{T(5\text{min}) - T(\infty)}{T_i - T(\infty)} = \frac{T(5\text{min}) - 100^\circ \text{C}}{(20 - 100)^\circ \text{C}} = \exp\left[-\frac{5 \times 60\text{s}}{1.33 \text{ K/W} \times 285 \text{ J/K}}\right] = 0.453$$

$$T(5\text{min}) = 100^\circ \text{C} + (20 - 100)^\circ \text{C} \times 0.453 = 63.8^\circ \text{C} <$$

COMMENTS: Eq. 5.24 may be used directly for Part (b) with $a = \bar{h}A_s/Mc$ and $b = \dot{E}_g / Mc$.

PROBLEM 5.21

KNOWN: Spherical coal pellet at 25°C is heated by radiation while flowing through a furnace maintained at 1000°C.

FIND: Length of tube required to heat pellet to 600°C.

SCHEMATIC:

ASSUMPTIONS: (1) Pellet is suspended in air flow and subjected to only radiative exchange with furnace, (2) Pellet is small compared to furnace surface area, (3) Coal pellet has emissivity, $\epsilon = 1$.

PROPERTIES: Table A-3, Coal ($\bar{T} = (600 + 25)^\circ \text{C} / 2 = 585 \text{K}$, however, only 300K data available): $\rho = 1350 \text{ kg/m}^3$, $c_p = 1260 \text{ J/kg} \cdot \text{K}$, $k = 0.26 \text{ W/m} \cdot \text{K}$.

ANALYSIS: Considering the pellet as spatially isothermal, use the lumped capacitance method of Section 5.3 to find the time required to heat the pellet from $T_o = 25^\circ \text{C}$ to $T_L = 600^\circ \text{C}$. From an energy balance on the pellet $\dot{E}_{\text{in}} = \dot{E}_{\text{st}}$ where

$$\dot{E}_{\text{in}} = q_{\text{rad}} = \sigma A_s (T_{\text{sur}}^4 - T_s^4) \quad \dot{E}_{\text{st}} = \rho \forall c_p \frac{dT}{dt}$$

giving $A_s \sigma (T_{\text{sur}}^4 - T_s^4) = \rho \forall c_p \frac{dT}{dt}$.

Separating variables and integrating with limits shown, the temperature-time relation becomes

$$\frac{A_s \sigma}{\rho \forall c_p} \int_0^t dt = \int_{T_o}^{T_L} \frac{dT}{T_{\text{sur}}^4 - T^4}.$$

The integrals are evaluated in Eq. 5.18 giving

$$t = \frac{\rho \forall c_p}{4 A_s \sigma T_{\text{sur}}^3} \left\{ \ln \left| \frac{T_{\text{sur}} + T}{T_{\text{sur}} - T} \right| - \ln \left| \frac{T_{\text{sur}} + T_i}{T_{\text{sur}} - T_i} \right| + 2 \left[\tan^{-1} \left[\frac{T}{T_{\text{sur}}} \right] - \tan^{-1} \left[\frac{T_i}{T_{\text{sur}}} \right] \right] \right\}.$$

Recognizing that $A_s = \pi D^2$ and $\forall = \pi D^3 / 6$ or $A_s / \forall = 6 / D$ and substituting values,

$$t = \frac{1350 \text{ kg/m}^3 (0.001 \text{ m}) 1260 \text{ J/kg} \cdot \text{K}}{24 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1273 \text{ K})^3} \left\{ \ln \frac{1273 + 873}{1273 - 873} - \ln \frac{1273 + 298}{1273 - 298} + 2 \left[\tan^{-1} \left(\frac{873}{1273} \right) - \tan^{-1} \left(\frac{298}{1273} \right) \right] \right\} = 1.18 \text{ s}.$$

Hence, $L = V \cdot t = 3 \text{ m/s} \times 1.18 \text{ s} = 3.54 \text{ m}.$

The validity of the lumped capacitance method requires $Bi = h(\forall / A_s) / k < 0.1$. Using Eq. (1.9) for $h = h_r$ and $\forall / A_s = D / 6$, find that when $T = 600^\circ \text{C}$, $Bi = 0.19$; but when $T = 25^\circ \text{C}$, $Bi = 0.10$. At early times, when the pellet is cooler, the assumption is reasonable but becomes less appropriate as the pellet heats.

PROBLEM 5.22

KNOWN: Metal sphere, initially at a uniform temperature T_i , is suddenly removed from a furnace and suspended in a large room and subjected to a convection process (T_∞ , h) and to radiation exchange with surroundings, T_{sur} .

FIND: (a) Time it takes for sphere to cool to some temperature T , neglecting radiation exchange, (b) Time it takes for sphere to cool to some temperature t , neglecting convection, (c) Procedure to obtain time required if both convection and radiation are considered, (d) Time to cool an anodized aluminum sphere to 400 K using results of Parts (a), (b) and (c).

SCHEMATIC:

ASSUMPTIONS: (1) Sphere is spacewise isothermal, (2) Constant properties, (3) Constant heat transfer convection coefficient, (4) Sphere is small compared to surroundings.

PROPERTIES: Table A-1, Aluminum, pure ($\bar{T} = [800 + 400] K/2 = 600 K$): $\rho = 2702 \text{ kg/m}^3$, $c = 1033 \text{ J/kg}\cdot\text{K}$, $k = 231 \text{ W/m}\cdot\text{K}$, $\alpha = k/\rho c = 8.276 \times 10^{-5} \text{ m}^2/\text{s}$; Aluminum, anodized finish: $\varepsilon = 0.75$, polished surface: $\varepsilon = 0.1$.

ANALYSIS: (a) Neglecting radiation, the time to cool is predicted by Eq. 5.5,

$$t = \frac{\rho V c}{h A_s} \ln \frac{\theta_i}{\theta} = \frac{\rho D c}{6 h} \ln \frac{T_i - T_\infty}{T - T_\infty} \quad (1) <$$

where $V/A_s = (\pi D^3/6)/(\pi D^2) = D/6$ for the sphere.

(b) Neglecting convection, the time to cool is predicted by Eq. 5.18,

$$t = \frac{\rho D c}{24 \varepsilon \sigma T_{sur}^3} \left\{ \ln \left| \frac{T_{sur} + T}{T_{sur} - T} \right| - \ln \left| \frac{T_{sur} + T_i}{T_{sur} - T_i} \right| + 2 \left[\tan^{-1} \left(\frac{T}{T_{sur}} \right) - \tan^{-1} \left(\frac{T_i}{T_{sur}} \right) \right] \right\} \quad (2)$$

where $V/A_{s,r} = D/6$ for the sphere.

(c) If convection and radiation exchange are considered, the energy balance requirement results in Eq. 5.15 (with $q_s'' = \dot{E}_g = 0$). Hence

$$\frac{dT}{dt} = \frac{6}{\rho D c} \left[h(T - T_\infty) + \varepsilon \sigma (T^4 - T_{sur}^4) \right] \quad (3) <$$

where $A_{s(c,r)} = A_s = \pi D^2$ and $V/A_{s(c,r)} = D/6$. This relation must be solved numerically in order to evaluate the time-to-cool.

(d) For the aluminum (pure) sphere with an anodized finish and the prescribed conditions, the times to cool from $T_i = 800 \text{ K}$ to $T = 400 \text{ K}$ are:

Continued...

PROBLEM 5.22 (Cont.)

Convection only, Eq. (1)

$$t = \frac{2702 \text{ kg/m}^3 \times 0.050 \text{ m} \times 1033 \text{ J/kg} \cdot \text{K}}{6 \times 10 \text{ W/m}^2 \cdot \text{K}} \ln \frac{800 - 300}{400 - 300} = 3743 \text{ s} = 1.04 \text{ h}$$

<

Radiation only, Eq. (2)

$$t = \frac{2702 \text{ kg/m}^3 \times 0.050 \text{ m} \times 1033 \text{ J/kg} \cdot \text{K}}{24 \times 0.75 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (300 \text{ K})^3} \cdot \left\{ \left(\ln \frac{400 + 300}{400 - 300} - \ln \frac{800 + 300}{800 - 300} \right) + 2 \left[\tan^{-1} \frac{400}{300} - \tan^{-1} \frac{800}{300} \right] \right\}$$

$$t = 5.065 \times 10^3 \{ 1.946 - 0.789 + 2(0.927 - 1.212) \} = 2973 \text{ s} = 0.826 \text{ h}$$

<

Radiation and convection, Eq. (3)

Using the IHT Lumped Capacitance Model, numerical integration yields

$$t \approx 1600 \text{ s} = 0.444 \text{ h}$$

In this case, heat loss by radiation exerts the stronger influence, although the effects of convection are by no means negligible. However, if the surface is polished ($\epsilon = 0.1$), convection clearly dominates. For each surface finish and the three cases, the temperature histories are as follows.

COMMENTS: 1. A summary of the analyses shows the relative importance of the various modes of heat loss:

Active Modes	Time required to cool to 400 K (h)	
	$\epsilon = 0.75$	$\epsilon = 0.1$
Convection only	1.040	1.040
Radiation only	0.827	6.194
Both modes	0.444	0.889

2. Note that the spacewise isothermal assumption is justified since $Be \ll 0.1$. For the convection-only process,

$$Bi = h(r_o/3)/k = 10 \text{ W/m}^2 \cdot \text{K} (0.025 \text{ m}/3) / 231 \text{ W/m} \cdot \text{K} = 3.6 \times 10^{-4}$$

PROBLEM 5.23

KNOWN: Droplet properties, diameter, velocity and initial and final temperatures.

FIND: Travel distance and rejected thermal energy.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation from space.

PROPERTIES: Droplet (given): $\rho = 885 \text{ kg/m}^3$, $c = 1900 \text{ J/kg}\cdot\text{K}$, $k = 0.145 \text{ W/m}\cdot\text{K}$, $\varepsilon = 0.95$.

ANALYSIS: To assess the suitability of applying the lumped capacitance method, use Equation 1.9 to obtain the maximum radiation coefficient, which corresponds to $T = T_i$.

$$h_r = \varepsilon \sigma T_i^3 = 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (500 \text{ K})^3 = 6.73 \text{ W/m}^2 \cdot \text{K}.$$

Hence

$$Bi_r = \frac{h_r (r_o/3)}{k} = \frac{(6.73 \text{ W/m}^2 \cdot \text{K}) (0.25 \times 10^{-3} \text{ m/3})}{0.145 \text{ W/m}\cdot\text{K}} = 0.0039$$

and the lumped capacitance method can be used. From Equation 5.19,

$$t = \frac{L}{V} = \frac{\rho c (\pi D^3/6) \left(\frac{1}{T_f^3} - \frac{1}{T_i^3} \right)}{3 \varepsilon (\pi D^2) \sigma \left(\frac{1}{T_f^3} - \frac{1}{T_i^3} \right)}$$

$$L = \frac{(0.1 \text{ m/s}) 885 \text{ kg/m}^3 (1900 \text{ J/kg}\cdot\text{K}) 0.5 \times 10^{-3} \text{ m} \left(\frac{1}{300^3} - \frac{1}{500^3} \right) \frac{1}{\text{K}^3}}{18 \times 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}$$

$$L = 2.52 \text{ m.}$$

The amount of energy rejected by each droplet is equal to the change in its internal energy.

$$E_i - E_f = \rho V c (T_i - T_f) = 885 \text{ kg/m}^3 \pi \frac{(5 \times 10^{-4} \text{ m})^3}{6} 1900 \text{ J/kg}\cdot\text{K} (200 \text{ K})$$

$$E_i - E_f = 0.022 \text{ J.}$$

COMMENTS: Because some of the radiation emitted by a droplet will be intercepted by other droplets in the stream, the foregoing analysis overestimates the amount of heat dissipated by radiation to space.

PROBLEM 5.24

KNOWN: Initial and final temperatures of a niobium sphere. Diameter and properties of the sphere. Temperature of surroundings and/or gas flow, and convection coefficient associated with the flow.

FIND: (a) Time required to cool the sphere exclusively by radiation, (b) Time required to cool the sphere exclusively by convection, (c) Combined effects of radiation and convection.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform temperature at any time, (2) Negligible effect of holding mechanism on heat transfer, (3) Constant properties, (4) Radiation exchange is between a small surface and large surroundings.

ANALYSIS: (a) If cooling is exclusively by radiation, the required time is determined from Eq. (5.18). With $V = \pi D^3/6$, $A_{s,r} = \pi D^2$, and $\epsilon = 0.1$,

$$t = \frac{8600 \text{ kg/m}^3 (290 \text{ J/kg} \cdot \text{K}) 0.01 \text{ m}}{24 (0.1) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298 \text{ K})^3} \left\{ \ln \left| \frac{298 + 573}{298 - 573} \right| - \ln \left| \frac{298 + 1173}{298 - 1173} \right| \right. \\ \left. + 2 \left[\tan^{-1} \left(\frac{573}{298} \right) - \tan^{-1} \left(\frac{1173}{298} \right) \right] \right\}$$

$$t = 6926 \text{ s} \{ 1.153 - 0.519 + 2(1.091 - 1.322) \} = 1190 \text{ s} \quad (\epsilon = 0.1) \quad <$$

If $\epsilon = 0.6$, cooling is six times faster, in which case,

$$t = 199 \text{ s} \quad (\epsilon = 0.6) \quad <$$

(b) If cooling is exclusively by convection, Eq. (5.5) yields

$$t = \frac{\rho c D}{6h} \ln \left(\frac{T_i - T_\infty}{T_f - T_\infty} \right) = \frac{8600 \text{ kg/m}^3 (290 \text{ J/kg} \cdot \text{K}) 0.010 \text{ m}}{1200 \text{ W/m}^2 \cdot \text{K}} \ln \left(\frac{875}{275} \right)$$

$$t = 24.1 \text{ s} \quad <$$

(c) With both radiation and convection, the temperature history may be obtained from Eq. (5.15).

$$\rho \left(\pi D^3 / 6 \right) c \frac{dT}{dt} = -\pi D^2 \left[h(T - T_\infty) + \epsilon \sigma (T^4 - T_{\text{sur}}^4) \right]$$

Integrating numerically from $T_i = 1173 \text{ K}$ at $t = 0$ to $T = 573 \text{ K}$, we obtain

$$t = 21.0 \text{ s} \quad <$$

Continued

PROBLEM 5.24 (Cont.)

Cooling times corresponding to representative changes in ϵ and h are tabulated as follows

$h(\text{W/m}^2 \cdot \text{K})$	200	200	20	500
ϵ	0.6	1.0	0.6	0.6
$t(\text{s})$	21.0	19.4	102.8	9.1

For values of h representative of forced convection, the influence of radiation is secondary, even for a maximum possible emissivity of 1.0. Hence, to accelerate cooling, it is necessary to increase h . However, if cooling is by natural convection, radiation is significant. For a representative natural convection coefficient of $h = 20 \text{ W/m}^2 \cdot \text{K}$, the radiation flux exceeds the convection flux at the surface of the sphere during early to intermediate stages of the transient.

COMMENTS: (1) Even for h as large as $500 \text{ W/m}^2 \cdot \text{K}$, $\text{Bi} = h(D/6)/k = 500 \text{ W/m}^2 \cdot \text{K} (0.01\text{m}/6)/63 \text{ W/m} \cdot \text{K} = 0.013 < 0.1$ and the lumped capacitance model is appropriate. (2) The largest value of h_r corresponds to $T_i = 1173 \text{ K}$, and for $\epsilon = 0.6$ Eq. (1.9) yields $h_r = 0.6 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1173 + 298)^3 \text{ K}^3 = 73.3 \text{ W/m}^2 \cdot \text{K}$.

PROBLEM 5.25

KNOWN: Diameter and thermophysical properties of alumina particles. Convection conditions associated with a two-step heating process.

FIND: (a) Time-in-flight (t_{i-f}) required for complete melting, (b) Validity of assuming negligible radiation.

SCHEMATIC:

ASSUMPTIONS: (1) Particle behaves as a lumped capacitance, (2) Negligible radiation, (3) Constant properties.

ANALYSIS: (a) The two-step process involves (i) the time t_1 to heat the particle to its melting point and (ii) the time t_2 required to achieve complete melting. Hence, $t_{i-f} = t_1 + t_2$, where from Eq. (5.5),

$$t_1 = \frac{\rho_p V c_p}{h A_s} \ln \frac{\theta_i}{\theta} = \frac{\rho_p D_p c_p}{6h} \ln \frac{T_i - T_\infty}{T_{mp} - T_\infty}$$

$$t_1 = \frac{3970 \text{ kg/m}^3 (50 \times 10^{-6} \text{ m}) 1560 \text{ J/kg} \cdot \text{K}}{6 (30,000 \text{ W/m}^2 \cdot \text{K})} \ln \frac{(300 - 10,000)}{(2318 - 10,000)} = 4 \times 10^{-4} \text{ s}$$

Performing an energy balance for the second step, we obtain

$$\int_{t_1}^{t_1+t_2} q_{conv} dt = \Delta E_{st}$$

where $q_{conv} = h A_s (T_\infty - T_{mp})$ and $\Delta E_{st} = \rho_p V h_{sf}$. Hence,

$$t_2 = \frac{\rho_p D_p}{6h} \frac{h_{sf}}{(T_\infty - T_{mp})} = \frac{3970 \text{ kg/m}^3 (50 \times 10^{-6} \text{ m})}{6 (30,000 \text{ W/m}^2 \cdot \text{K})} \times \frac{3.577 \times 10^6 \text{ J/kg}}{(10,000 - 2318) \text{ K}} = 5 \times 10^{-4} \text{ s}$$

Hence $t_{i-f} = 9 \times 10^{-4} \text{ s} \approx 1 \text{ ms}$

<

(b) Contrasting the smallest value of the convection heat flux, $q''_{conv,min} = h(T_\infty - T_{mp}) = 2.3 \times 10^8 \text{ W/m}^2$ to the largest radiation flux, $q''_{rad,max} = \varepsilon \sigma (T_{mp}^4 - T_{sur}^4) = 6.7 \times 10^5 \text{ W/m}^2$, with $\varepsilon = 0.41$ from Table A.11 for aluminum oxide at 1500 K, and $T_{sur} = 300 \text{ K}$ we conclude that radiation is, in fact, negligible.

COMMENTS: (1) Since $Bi = (h r_p / 3) / k \approx 0.02$, the lumped capacitance assumption is good. (2) In an actual application, the droplet should impact the substrate in a superheated condition ($T > T_{mp}$), which would require a slightly larger t_{i-f} .

PROBLEM 5.26

KNOWN: Diameters, initial temperature and thermophysical properties of WC and Co in composite particle. Convection coefficient and freestream temperature of plasma gas. Melting point and latent heat of fusion of Co.

FIND: Times required to reach melting and to achieve complete melting of Co.

SCHEMATIC:

ASSUMPTIONS: (1) Particle is isothermal at any instant, (2) Radiation exchange with surroundings is negligible, (3) Negligible contact resistance at interface between WC and Co, (4) Constant properties.

ANALYSIS: From Eq. (5.5), the time required to reach the melting point is

$$t_1 = \frac{(\rho V c)_{\text{tot}}}{h \pi D_o^2} \ln \frac{T_i - T_\infty}{T_{\text{mp}} - T_\infty}$$

where the total heat capacity of the composite particle is

$$\begin{aligned} (\rho V c)_{\text{tot}} &= (\rho V c)_c + (\rho V c)_s = 16,000 \text{ kg/m}^3 \left[\pi (1.6 \times 10^{-5} \text{ m})^3 / 6 \right] 300 \text{ J/kg} \cdot \text{K} \\ &\quad + 8900 \text{ kg/m}^3 \left\{ \pi / 6 \left[(2.0 \times 10^{-5} \text{ m})^3 - (1.6 \times 10^{-5} \text{ m})^3 \right] \right\} 750 \text{ J/kg} \cdot \text{K} \\ &= (1.03 \times 10^{-8} + 1.36 \times 10^{-8}) \text{ J/K} = 2.39 \times 10^{-8} \text{ J/K} \end{aligned}$$

$$t_1 = \frac{2.39 \times 10^{-8} \text{ J/K}}{(20,000 \text{ W/m}^2 \cdot \text{K}) \pi (2.0 \times 10^{-5} \text{ m})^2} \ln \frac{(300 - 10,000) \text{ K}}{(1770 - 10,000) \text{ K}} = 1.56 \times 10^{-4} \text{ s} <$$

The time required to melt the Co may be obtained by applying the first law, Eq. (1.11b) to a control surface about the particle. It follows that

$$\begin{aligned} E_{\text{in}} &= h \pi D_o^2 (T_\infty - T_{\text{mp}}) t_2 = \Delta E_{\text{st}} = \rho_s (\pi / 6) (D_o^3 - D_i^3) h_{\text{sf}} \\ t_2 &= \frac{8900 \text{ kg/m}^3 (\pi / 6) \left[(2 \times 10^{-5} \text{ m})^3 - (1.6 \times 10^{-5} \text{ m})^3 \right] 2.59 \times 10^5 \text{ J/kg}}{(20,000 \text{ W/m}^2 \cdot \text{K}) \pi (2 \times 10^{-5} \text{ m})^2 (10,000 - 1770) \text{ K}} = 2.28 \times 10^{-5} \text{ s} < \end{aligned}$$

COMMENTS: (1) The largest value of the radiation coefficient corresponds to $h_r = \varepsilon \sigma (T_{\text{mp}} + T_{\text{sur}})(T_{\text{mp}}^2 + T_{\text{sur}}^2)$. For the maximum possible value of $\varepsilon = 1$ and $T_{\text{sur}} = 300 \text{ K}$, $h_r = 378 \text{ W/m}^2 \cdot \text{K} \ll h = 20,000 \text{ W/m}^2 \cdot \text{K}$. Hence, the assumption of negligible radiation exchange is excellent. (2) Despite the large value of h , the small values of D_o and D_i and the large thermal conductivities ($\sim 40 \text{ W/m} \cdot \text{K}$ and $70 \text{ W/m} \cdot \text{K}$ for WC and Co, respectively) render the lumped capacitance approximation a good one. (3) A detailed treatment of plasma heating of a composite powder particle is provided by Demetriou, Lavine and Ghoniem (Proc. 5th ASME/JSME Joint Thermal Engineering Conf., March, 1999).

PROBLEM 5.27

KNOWN: Dimensions and operating conditions of an integrated circuit.

FIND: Steady-state temperature and time to come within 1°C of steady-state.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible heat transfer from chip to substrate.

PROPERTIES: Chip material (given): $\rho = 2000 \text{ kg/m}^3$, $c = 700 \text{ J/kg} \cdot \text{K}$.

ANALYSIS: At steady-state, conservation of energy yields

$$\begin{aligned} -\dot{E}_{\text{out}} + \dot{E}_g &= 0 \\ -h(L^2)(T_f - T_\infty) + \dot{q}(L^2 \cdot t) &= 0 \\ T_f &= T_\infty + \frac{\dot{q}t}{h} \end{aligned}$$

$$T_f = 20^\circ\text{C} + \frac{9 \times 10^6 \text{ W/m}^3 \times 0.001 \text{ m}}{150 \text{ W/m}^2 \cdot \text{K}} = 80^\circ\text{C}.$$

<

From the general lumped capacitance analysis, Equation 5.15 reduces to

$$\rho(L^2 \cdot t)c \frac{dT}{dt} = \dot{q}(L^2 \cdot t) - h(T - T_\infty)L^2.$$

With

$$\begin{aligned} a &\equiv \frac{h}{\rho tc} = \frac{150 \text{ W/m}^2 \cdot \text{K}}{(2000 \text{ kg/m}^3)(0.001 \text{ m})(700 \text{ J/kg} \cdot \text{K})} = 0.107 \text{ s}^{-1} \\ b &\equiv \frac{\dot{q}}{\rho c} = \frac{9 \times 10^6 \text{ W/m}^3}{(2000 \text{ kg/m}^3)(700 \text{ J/kg} \cdot \text{K})} = 6.429 \text{ K/s}. \end{aligned}$$

From Equation 5.24,

$$\begin{aligned} \exp(-at) &= \frac{T - T_\infty - b/a}{T_i - T_\infty - b/a} = \frac{(79 - 20 - 60) \text{ K}}{(20 - 20 - 60) \text{ K}} = 0.01667 \\ t &= -\frac{\ln(0.01667)}{0.107 \text{ s}^{-1}} = 38.3 \text{ s}. \end{aligned}$$

<

COMMENTS: Due to additional heat transfer from the chip to the substrate, the actual values of T_f and t are less than those which have been computed.

PROBLEM 5.28

KNOWN: Dimensions and operating conditions of an integrated circuit.

FIND: Steady-state temperature and time to come within 1°C of steady-state.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties.

PROPERTIES: Chip material (given): $\rho = 2000 \text{ kg/m}^3$, $c_p = 700 \text{ J/kg}\cdot\text{K}$.

ANALYSIS: The direct and indirect paths for heat transfer from the chip to the coolant are in parallel, and the equivalent resistance is

$$R_{\text{equiv}} = \left[hL^2 + R_t^{-1} \right]^{-1} = \left[\left(3.75 \times 10^{-3} + 5 \times 10^{-3} \right) \text{ W/K} \right]^{-1} = 114.3 \text{ K/W}.$$

The corresponding overall heat transfer coefficient is

$$U = \frac{(R_{\text{equiv}})^{-1}}{L^2} = \frac{0.00875 \text{ W/K}}{(0.005 \text{ m})^2} = 350 \text{ W/m}^2 \cdot \text{K}.$$

To obtain the steady-state temperature, apply conservation of energy to a control surface about the chip.

$$-\dot{E}_{\text{out}} + \dot{E}_g = 0 \quad -UL^2(T_f - T_\infty) + \dot{q}(L^2 \cdot t) = 0$$

$$T_f = T_\infty + \frac{\dot{q}t}{U} = 20^\circ\text{C} + \frac{9 \times 10^6 \text{ W/m}^3 \times 0.001 \text{ m}}{350 \text{ W/m}^2 \cdot \text{K}} = 45.7^\circ\text{C}.$$

From the general lumped capacitance analysis, Equation 5.15 yields

$$\rho(L^2t)c \frac{dT}{dt} = \dot{q}(L^2t) - U(T - T_\infty)L^2.$$

With

$$a \equiv \frac{U}{\rho tc} = \frac{350 \text{ W/m}^2 \cdot \text{K}}{(2000 \text{ kg/m}^3)(0.001 \text{ m})(700 \text{ J/kg} \cdot \text{K})} = 0.250 \text{ s}^{-1}$$

$$b \equiv \frac{\dot{q}}{\rho c} = \frac{9 \times 10^6 \text{ W/m}^3}{(2000 \text{ kg/m}^3)(700 \text{ J/kg} \cdot \text{K})} = 6.429 \text{ K/s}$$

Equation 5.24 yields

$$\exp(-at) = \frac{T - T_\infty - b/a}{T_i - T_\infty - b/a} = \frac{(44.7 - 20 - 25.7) \text{ K}}{(20 - 20 - 25.7) \text{ K}} = 0.0389$$

$$t = -\ln(0.0389)/0.250 \text{ s}^{-1} = 13.0 \text{ s}.$$

COMMENTS: Heat transfer through the substrate is comparable to that associated with direct convection to the coolant.

PROBLEM 5.29

KNOWN: Dimensions, initial temperature and thermophysical properties of chip, solder and substrate. Temperature and convection coefficient of heating agent.

FIND: (a) Time constants and temperature histories of chip, solder and substrate when heated by an air stream. Time corresponding to maximum stress on a solder ball. (b) Reduction in time associated with using a dielectric liquid to heat the components.

SCHEMATIC:

ASSUMPTIONS: (1) Lumped capacitance analysis is valid for each component, (2) Negligible heat transfer between components, (3) Negligible reduction in surface area due to contact between components, (4) Negligible radiation for heating by air stream, (5) Uniform convection coefficient among components, (6) Constant properties.

ANALYSIS: (a) From Eq. (5.7), $\tau_t = (\rho V c) / hA$

$$\text{Chip: } V = (L_{ch}^2) t_{ch} = (0.015\text{m})^2 (0.002\text{m}) = 4.50 \times 10^{-7} \text{ m}^3, A_s = (2L_{ch}^2 + 4L_{ch} t_{ch}) \\ = 2(0.015\text{m})^2 + 4(0.015\text{m})(0.002\text{m}) = 5.70 \times 10^{-4} \text{ m}^2$$

$$\tau_t = \frac{2300 \text{ kg/m}^3 \times 4.50 \times 10^{-7} \text{ m}^3 \times 710 \text{ J/kg} \cdot \text{K}}{50 \text{ W/m}^2 \cdot \text{K} \times 5.70 \times 10^{-4} \text{ m}^2} = 25.8\text{s} \quad <$$

$$\text{Solder: } V = \pi D^3 / 6 = \pi (0.002\text{m})^3 / 6 = 4.19 \times 10^{-9} \text{ m}^3, A_s = \pi D^2 = \pi (0.002\text{m})^2 = 1.26 \times 10^{-5} \text{ m}^2 \\ \tau_t = \frac{11,000 \text{ kg/m}^3 \times 4.19 \times 10^{-9} \text{ m}^3 \times 130 \text{ J/kg} \cdot \text{K}}{50 \text{ W/m}^2 \cdot \text{K} \times 1.26 \times 10^{-5} \text{ m}^2} = 9.5\text{s} \quad <$$

$$\text{Substrate: } V = (L_{sb}^2) t_{sb} = (0.025\text{m})^2 (0.01\text{m}) = 6.25 \times 10^{-6} \text{ m}^3, A_s = L_{sb}^2 = (0.025\text{m})^2 = 6.25 \times 10^{-4} \text{ m}^2 \\ \tau_t = \frac{4000 \text{ kg/m}^3 \times 6.25 \times 10^{-6} \text{ m}^3 \times 770 \text{ J/kg} \cdot \text{K}}{50 \text{ W/m}^2 \cdot \text{K} \times 6.25 \times 10^{-4} \text{ m}^2} = 616.0\text{s} \quad <$$

Substituting Eq. (5.7) into (5.5) and recognizing that $(T - T_i)/(T_\infty - T_i) = 1 - (\theta/\theta_i)$, in which case $(T - T_i)/(T_\infty - T_i) = 0.99$ yields $\theta/\theta_i = 0.01$, it follows that the time required for a component to experience 99% of its maximum possible temperature rise is

$$t_{0.99} = \tau \ln(\theta_i / \theta) = \tau \ln(100) = 4.61 \tau$$

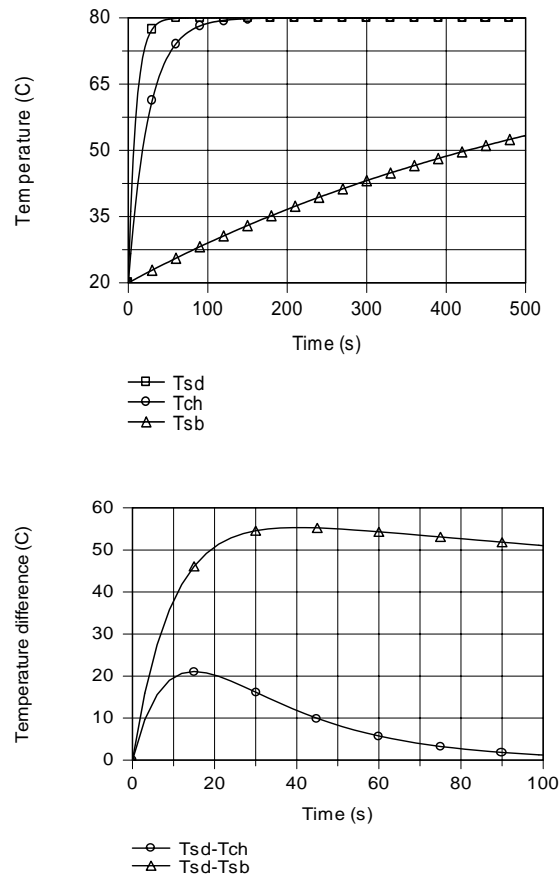

Hence,

$$\text{Chip: } t = 118.9\text{s}, \quad \text{Solder: } t = 43.8\text{s}, \quad \text{Substrate: } t = 2840 \quad <$$

Continued

PROBLEM 5.29 (Cont.)

Histories of the three components and temperature differences between a solder ball and its adjoining components are shown below.

Commensurate with their time constants, the fastest and slowest responses to heating are associated with the solder and substrate, respectively. Accordingly, the largest temperature difference is between these two components, and it achieves a maximum value of 55°C at

$$t(\text{maximum stress}) \approx 40\text{s}$$

<

(b) With the 4-fold increase in h associated with use of a dielectric liquid to heat the components, the time constants are each reduced by a factor of 4, and the times required to achieve 99% of the maximum temperature rise are

$$\text{Chip: } t = 29.5\text{s}, \quad \text{Solder: } t = 11.0\text{s}, \quad \text{Substrate: } t = 708\text{s}$$

<

The time savings is approximately 75%.

COMMENTS: The foregoing analysis provides only a first, albeit useful, approximation to the heating problem. Several of the assumptions are highly approximate, particularly that of a uniform convection coefficient. The coefficient will vary between components, as well as on the surfaces of the components. Also, because the solder balls are flattened, there will be a reduction in surface area exposed to the fluid for each component, as well as heat transfer between components, which reduces differences between time constants for the components.

PROBLEM 5.30

KNOWN: Electrical transformer of approximate cubical shape, 32 mm to a side, dissipates 4.0 W when operating in ambient air at 20°C with a convection coefficient of 10 W/m²·K.

FIND: (a) Develop a model for estimating the steady-state temperature of the transformer, $T(\infty)$, and evaluate $T(\infty)$, for the operating conditions, and (b) Develop a model for estimating the temperature-time history of the transformer if initially the temperature is $T_i = T_\infty$ and suddenly power is applied. Determine the time required to reach within 5°C of its steady-state operating temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Transformer is spatially isothermal object, (2) Initially object is in equilibrium with its surroundings, (3) Bottom surface is adiabatic.

ANALYSIS: (a) Under steady-state conditions, for the control volume shown in the schematic above, the energy balance is

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0 \quad 0 - q_{cv} + P_e = -h A_s [T(\infty) - T_\infty] + P_e = 0 \quad (1)$$

where $A_s = 5 \times L^2 = 5 \times 0.032\text{m} \times 0.032\text{m} = 5.12 \times 10^{-3} \text{ m}^2$, find

$$T(\infty) = T_\infty + P_e / h A_s = 20^\circ\text{C} + 4 \text{ W} / (10 \text{ W/m}^2 \cdot \text{K} \times 5.12 \times 10^{-3} \text{ m}^2) = 98.1^\circ\text{C} <$$

(b) Under transient conditions, for the control volume shown above, the energy balance is

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = \dot{E}_{st} \quad 0 - q_{cv} + P_e = Mc \frac{dT}{dt} \quad (2)$$

Substitute from Eq. (1) for P_e , separate variables, and define the limits of integration.

$$-h [T(t) - T_\infty] + h [T(\infty) - T_\infty] = Mc \frac{dT}{dt}$$

$$-h [T(t) - T(\infty)] = Mc \frac{d}{dt} (T - T(\infty)) \quad \frac{h}{Mc} \int_0^{t_o} dt = -\int_{\theta_1}^{\theta_o} \frac{d\theta}{\theta}$$

where $\theta = T(t) - T(\infty)$; $\theta_i = T_i - T(\infty) = T_\infty - T(\infty)$; and $\theta_o = T(t_o) - T(\infty)$ with t_o as the time when $\theta_o = -5^\circ\text{C}$. Integrating and rearranging find (see Eq. 5.5),

$$t_o = \frac{Mc}{h A_s} \ln \frac{\theta_i}{\theta_o}$$

$$t_o = \frac{0.28 \text{ kg} \times 400 \text{ J/kg} \cdot \text{K}}{10 \text{ W/m}^2 \cdot \text{K} \times 5.12 \times 10^{-3} \text{ m}^2} \ln \frac{(20 - 98.1)^\circ\text{C}}{-5^\circ\text{C}} = 1.67 \text{ hour} <$$

COMMENTS: The spacewise isothermal assumption may not be a gross over simplification since most of the material is copper and iron, and the external resistance by free convection is high.

However, by ignoring internal resistance, our estimate for t_o is optimistic.

PROBLEM 5.31

KNOWN: Mass and exposed surface area of a silicon cantilever, convection heat transfer coefficient, initial and ambient temperatures.

FIND: (a) The ohmic heating needed to raise the cantilever temperature from $T_i = 300$ K to $T = 1000$ K in $t_h = 1 \mu\text{s}$, (b) The time required to cool the cantilever from $T = 1000$ K to $T = 400$ K, t_c and the thermal processing time ($t_p = t_h + t_c$), (c) The number of bits that can be written onto a $1 \text{ mm} \times 1 \text{ mm}$ surface area and time needed to write the data for a processing head equipped with M cantilevers.

SCHEMATIC:

ASSUMPTIONS: (1) Lumped capacitance behavior, (2) Negligible radiation heat transfer, (3) Constant properties, (4) Negligible heat transfer to polymer substrate.

PROPERTIES: Table A.1, silicon ($\bar{T} = 650$ K): $c_p = 878.5$ J/kg·K.

ANALYSIS:

(a) From Problem 5.20 we note that

$$\frac{\theta}{\theta_i} = \exp\left(-\frac{t}{RC}\right) \quad (1)$$

where $\theta \equiv T - T(\infty)$ and $T(\infty)$ is the steady-state temperature corresponding to $t \rightarrow \infty$;

$\theta_i = T_i - T(\infty)$, $R = \frac{1}{hA_s}$, and $C = Mc_p$. For this problem,

$$R = \frac{1}{200 \times 10^3 \text{ W/m}^2 \cdot \text{K} \times 600 \times 10^{-15} \text{ m}^2} = 8.33 \times 10^6 \text{ K/W}$$

$$C = 50 \times 10^{-18} \text{ kg} \times 878.5 \text{ J/kg} \cdot \text{K} = 43.9 \times 10^{-15} \text{ J/K}$$

$$R \times C = 8.33 \times 10^6 \text{ K/W} \times 43.9 \times 10^{-15} \text{ J/K} = 366 \times 10^{-9} \text{ s}$$

Therefore, Equation 1 may be evaluated as

Continued...

PROBLEM 5.31 (Cont.)

$$\frac{1000 - T(\infty)}{300 - T(\infty)} = \exp \left(- \frac{1 \times 10^{-6} \text{ s}}{366 \times 10^{-9} \text{ s}} \right) = 0.0651$$

hence, $T(\infty) = 1049\text{K}$.

At steady-state, Equation 1.11b yields

$$\begin{aligned} \dot{E}_g &= hA_s(T(\infty) - T_\infty) = 200 \times 10^3 \text{ W/m}^2 \cdot \text{K} \times 600 \times 10^{-15} \text{ m}^2 (1049 - 300) \text{ K} \\ &= 90 \times 10^{-6} \text{ W} = 90 \mu\text{W} \end{aligned} \quad <$$

(b) Equation 5.6 may be used. Hence,

$$\frac{\theta}{\theta_i} = \exp \left[- \left(\frac{hA_s}{Mc} \right) t_c \right] \quad \text{where } \theta = T - T_\infty. \text{ Therefore}$$

$$\frac{400 - 300}{1000 - 300} = 0.143 = \exp \left[- \left(\frac{200 \times 10^3 \text{ W/m}^2 \cdot \text{K} \times 600 \times 10^{-15} \text{ m}^2}{50 \times 10^{-18} \text{ kg} \times 878.5 \text{ J/kg} \cdot \text{K}} \right) t_c \right]$$

$$\text{or } t_c = 0.71 \times 10^{-6} \text{ s} = 0.71 \mu\text{s} \quad <$$

$$\text{and } t_p = t_h + t_c = 1.0 \mu\text{s} + 0.71 \mu\text{s} = 1.71 \mu\text{s} \quad <$$

(c) Each bit occupies $A_b = 50 \times 10^{-9} \text{ m} \times 50 \times 10^{-9} \text{ m} = 2.5 \times 10^{-15} \text{ m}^2$

Therefore, the number of bits on a $1 \text{ mm} \times 1 \text{ mm}$ substrate is

$$N = \frac{1 \times 10^{-3} \times 1 \times 10^{-3} \text{ m}^2}{2.5 \times 10^{-15} \text{ m}^2} = 400 \times 10^6 \text{ bits} \quad <$$

The total time needed to write the data (t_t) is,

$$t_t = \frac{N \times t_p}{M} = \frac{400 \times 10^6 \text{ bits} \times 1.71 \times 10^{-6} \text{ s/bit}}{100} = 6.84 \text{ s} \quad <$$

COMMENTS: (1) Lumped thermal capacitance behavior is an excellent approximation for such a small device (2) Each cantilever writes $N/M = 400 \times 10^6 \text{ bits}/100 \text{ cantilevers} = 400 \times 10^4 \text{ bits/cantilever}$. With a separation distance of $50 \times 10^{-9} \text{ m}$, the total distance traveled is $50 \times 10^{-9} \text{ m} \times 400 \times 10^4 = 200 \times 10^{-3} \text{ m} = 200 \text{ mm}$. If the head travels at 200 mm/s , it will take 1 second to move the head, providing a total writing and moving time of $6.84 \text{ s} + 1 \text{ s} = 7.84 \text{ s}$. The speed of the process is heat transfer-limited.

PROBLEM 5.32

KNOWN: Ambient conditions, initial water droplet temperature and diameter.

FIND: Total time to completely freeze the water droplet for (a) droplet solidification at $T_f = 0^\circ\text{C}$ and (b) rapid solidification of the droplet at $T_{f,sc}$.

SCHEMATIC:

ASSUMPTIONS: (1) Isothermal particle, (2) Negligible radiation heat transfer, (3) Constant properties.

PROPERTIES: Table A.6, liquid water ($T = 0^\circ\text{C}$): $c_p = 4217 \text{ J/kg}\cdot\text{K}$, $k = 0.569 \text{ W/m}\cdot\text{K}$, $\rho = 1000 \text{ kg/m}^3$. Example 1.4: $h_{sf} = 334 \text{ kJ/kg}$.

ANALYSIS: We begin by evaluating the validity of the lumped capacitance method by determining the value of the Biot number.

$$B_i = \frac{hL_c}{k} = \frac{hD/3}{k} = \frac{900 \text{ W/m}^2 \cdot \text{K} \times 50 \times 10^{-6} \text{ m}/3}{0.569 \text{ W/m}\cdot\text{K}} = 0.026 \ll 0.1$$

Hence, the lumped capacitance approach is valid.

Case A: Equilibrium solidification, $T_f = 0^\circ\text{C}$.

The solidification process occurs in two steps. The first step involves cooling the drop to $T_f = 0^\circ\text{C}$ while the drop is completely liquid. Hence, Equation 5.6 is used where

$$A = \pi D^2 = \pi \times (50 \times 10^{-6} \text{ m})^2 = 7.85 \times 10^{-9} \text{ m}^2 \text{ and}$$

$$V = 4\pi(D/2)^3/3 = 4 \times \pi \times (50 \times 10^{-6} \text{ m}/2)^3/3 = 65.4 \times 10^{-15} \text{ m}^3. \text{ Equation 5.6 may be rearranged to yield}$$

$$t_1 = - \frac{\rho V c_p}{hA} \ln \left[\frac{T - T_\infty}{T_i - T_\infty} \right] \quad (1)$$

$$= - \frac{1000 \text{ kg/m}^3 \times 65.4 \times 10^{-15} \text{ m}^3 \times 4217 \text{ J/kg}\cdot\text{K}}{900 \text{ W/m}^2 \times 7.85 \times 10^{-9} \text{ m}^2} \times \ln \left[\frac{0 - (-40^\circ\text{C})}{10^\circ\text{C} - (-40^\circ\text{C})} \right]$$

$$t_1 = 8.7 \times 10^{-3} \text{ s} = 8.7 \text{ ms}$$

Continued...

PROBLEM 5.32 (Cont.)

The second step involves solidification of the ice, which occurs at $T_f = 0^\circ\text{C}$. An energy balance on the droplet yields

$$-E_{\text{out}} = \Delta E_{\text{st}} \quad \text{or} \quad -hA(T_f - T_\infty)t_2 = \rho V h_{\text{sf}}$$

which may be rearranged to provide

$$\begin{aligned} t_2 &= - \frac{\rho V h_{\text{sf}}}{hA(T_f - T_\infty)} \\ &= \frac{1000 \text{ kg/m}^3 \times 65.4 \times 10^{-15} \text{ m}^3 \times 334,000 \text{ J/kg}}{900 \text{ W/m}^2 \times 7.85 \times 10^{-9} \text{ m}^2 \times (0^\circ\text{C} - (-40)^\circ\text{C})} = 77.3 \times 10^{-3} \text{ s} = 77.3 \text{ ms} \end{aligned} \quad (2)$$

The time needed to cool and solidify the particle is

$$t = t_1 + t_2 = 8.7 \text{ ms} + 77.3 \text{ ms} = 86 \text{ ms} \quad <$$

Case B: Rapid solidification at $T_{f,\text{sc}}$

Using the expression given in the problem statement, the liquid droplet is supercooled to a temperature of $T_{f,\text{sc}}$ prior to freezing.

$$T_{f,\text{sc}} = -28 + 1.87 \ln(50 \times 10^{-6} \text{ m}) = -36.6^\circ\text{C}$$

The solidification process occurs in multiple steps, the first of which is cooling the particle to $T_{f,\text{sc}} = -36.6^\circ\text{C}$. Substituting $T = T_{f,\text{sc}}$ into Equation 1 yields

$$t_1 = 105 \times 10^{-3} \text{ s} = 105 \text{ ms}$$

The second step involves rapid solidification of some or all of the supercooled liquid. An energy balance on the particle yields

$$\dot{E}_{\text{st}} = 0 = \rho V h_{\text{sf}} f = \rho V c (T_f - T_{f,\text{sc}}) \quad (3)$$

where f is the fraction of the mass in the droplet that is converted to ice. Solving the preceding equation for f yields

$$f = \frac{c(T_f - T_{f,\text{sc}})}{h_{\text{sf}}} = \frac{4217 \text{ J/kg} \cdot \text{K} \times (0^\circ\text{C} - (-36.6^\circ\text{C}))}{334,000 \text{ J/kg}} = 0.462$$

Hence, immediately after the rapid solidification, the water droplet is approximately 46 percent ice and 54 percent liquid. The time required for the rapid solidification is $t_2 \approx 0 \text{ s}$.

The third stage of Case B involves the time required to freeze the remaining liquid water, t_3 . Equation 2 is modified accordingly to yield

$$\begin{aligned} t_3 &= - \frac{(1-f)\rho V h_{\text{sf}}}{hA(T_f - T_\infty)} \\ &= - \frac{(1 - 0.462) \times 1000 \text{ kg/m}^3 \times 65.4 \times 10^{-15} \text{ m}^3 \times 334,000 \text{ J/kg}}{900 \text{ W/m}^2 \times 7.85 \times 10^{-9} \text{ m}^2 \times (0^\circ\text{C} - (-40)^\circ\text{C})} = 42 \times 10^{-3} \text{ s} = 42 \text{ ms} \end{aligned}$$

Continued...

PROBLEM 5.32 (Cont.)

The total time to solidify the particle is

$$t = t_1 + t_2 + t_3 = 105 \text{ ms} + 0 + 42 \text{ s} = 147 \text{ ms}$$

<

The temperature histories associated with Case A and Case B are shown in the sketch below.

COMMENTS: (1) Equation 3 may be derived by assuming a reference temperature of $T_f = 0^\circ\text{C}$ and a liquid reference state. The energy of the particle prior to the rapid solidification is $E_1 = \rho V c (T_{f,sc} - T_f)$. The energy of the particle after the rapid solidification is $E_2 = -f \rho V h_{sf} + (1 - f) \rho V c (T_f - T_f) = -f \rho V h_{sf}$. Setting $E_1 = E_2$ yields Equation 3. (2) The average temperature of the supercooled particle is significantly lower than the average temperature of the particle of Case A. Hence, the rate at which the supercooled particle of Case B is cooled by the cold air is, on average, much less than the particle of Case A. Since both particles ultimately reach the same state (all ice at $T = 0^\circ\text{C}$), it takes longer to completely solidify the supercooled particle. (3) For Case A, the ice particle at $T = 0^\circ\text{C}$ will be a solid sphere, sometimes referred to as *sleet*. For Case B, the rapid solidification will result in a *snowflake*.

PROBLEM 5.33

KNOWN: Mass and initial temperature of frozen ground beef. Temperature and convection coefficient of air. Rate of microwave power absorbed in beef.

FIND: (a) Time for beef to reach 0°C, (b) Time for beef to be heated from liquid at 0°C to 80°C, and (c) Explain nonuniform heating in microwave and reason for low power setting for thawing.

SCHEMATIC:

ASSUMPTIONS: (1) Beef is nearly isothermal, (2) Beef has properties of water (ice or liquid), (3) Radiation is negligible, (4) Constant properties (different for ice and liquid water).

PROPERTIES: Table A.3, Ice (≈ 273 K): $\rho = 920$ kg/m³, $c = 2040$ J/kg·K, Table A.6, Water (≈ 315 K): $c = 4179$ J/kg·K.

ANALYSIS: (a) We apply conservation of energy to the beef

$$\begin{aligned}\dot{E}_{\text{in}} + \dot{E}_g &= \dot{E}_{\text{st}} \\ hA_s(T_{\infty} - T) + \dot{q} &= mc \frac{dT}{dt}\end{aligned}\quad (1)$$

The initial condition is $T(0) = T_i$. This differential equation can be solved by defining

$$\theta = T - T_{\infty} - \frac{\dot{q}}{hA_s}$$

Then Eq.(1) becomes $\frac{d\theta}{dt} = -\frac{hA_s}{mc}\theta$

Separating variables and integrating,

$$\begin{aligned}\int_{\theta(0)}^{\theta(t)} \frac{d\theta}{\theta} &= -\frac{hA_s}{mc} \int_0^t dt \\ \ln \left[\frac{\theta(t)}{\theta(0)} \right] &= -\frac{hA_s t}{mc} \\ \ln \left[\frac{T - T_{\infty} - \dot{q}/hA_s}{T_i - T_{\infty} - \dot{q}/hA_s} \right] &= -\frac{hA_s t}{mc}\end{aligned}\quad (2)$$

The heat generation rate is given by $\dot{q} = 0.03P = 0.03(1000 \text{ W}) = 30 \text{ W}$. The radius of the sphere can be found from knowledge of the mass and density:

Continued...

PROBLEM 5.33 (Cont.)

$$m = \rho V = \rho \frac{4}{3} \pi r_o^3$$

$$r_o = \left(\frac{3}{4\pi} \frac{m}{\rho} \right)^{1/3} = \left(\frac{3}{4\pi} \frac{1 \text{ kg}}{920 \text{ kg/m}^3} \right)^{1/3} = 0.0638 \text{ m}$$

Thus $A_s = 4\pi r_o^2 = 4\pi(0.0638 \text{ m})^2 = 0.0511 \text{ m}^2$

Substituting numerical values into Eq.(2), we can find the time at which the temperature reaches 0°C :

$$\ln \left[\frac{0^\circ\text{C} - 30^\circ\text{C} - 30 \text{ W}/(15 \text{ W/m}^2 \cdot \text{K} \times 0.0511 \text{ m}^2)}{-20^\circ\text{C} - 30^\circ\text{C} - 30 \text{ W}/(15 \text{ W/m}^2 \cdot \text{K} \times 0.0511 \text{ m}^2)} \right] = - \frac{15 \text{ W/m}^2 \cdot \text{K} \times 0.0511 \text{ m}^2}{1 \text{ kg} \times 2040 \text{ J/kg} \cdot \text{K}} t$$

Thus $t = 676 \text{ s} = 11.3 \text{ min}$

<

(b) After all the ice is converted to liquid, the absorbed power is $\dot{q} = 0.95P = 950 \text{ W}$. The time for the beef to reach 80°C can again be found from Eq.(2):

$$\ln \left[\frac{80^\circ\text{C} - 30^\circ\text{C} - 950 \text{ W}/(15 \text{ W/m}^2 \cdot \text{K} \times 0.0511 \text{ m}^2)}{0^\circ\text{C} - 30^\circ\text{C} - 950 \text{ W}/(15 \text{ W/m}^2 \cdot \text{K} \times 0.0511 \text{ m}^2)} \right] = - \frac{15 \text{ W/m}^2 \cdot \text{K} \times 0.0511 \text{ m}^2}{1 \text{ kg} \times 4179 \text{ J/kg} \cdot \text{K}} t$$

Thus $t = 355 \text{ s} = 5.9 \text{ min}$

<

(c) Microwave power is more efficiently absorbed in regions of liquid water. Therefore, if food or the microwave irradiation is not homogeneous or uniform, the power will be absorbed nonuniformly, resulting in a nonuniform temperature rise. Thawed regions will absorb more energy per unit volume than frozen regions. If food is of low thermal conductivity, there will be insufficient time for heat conduction to make the temperature more uniform. Use of low power allows more time for conduction to occur.

COMMENTS: (1) The time needed to turn the ice at 0°C into liquid water at 0°C was not calculated. The required energy is $Q = mh_{fg} = 1 \text{ kg} \times 2502 \text{ kJ/kg} = 2502 \text{ kJ}$. The required time depends on how the fraction of microwave power absorbed changes during the thawing process. The minimum possible time would be $t_{\min} = 2502 \text{ kJ}/950 \text{ W} = 2600 \text{ s} = 44 \text{ min}$. Therefore, the time to thaw is significant. (2) Radiation may not be negligible. It depends on the temperature of the oven walls and the emissivity of the beef. Radiation would contribute to heating the beef.

PROBLEM 5.34

KNOWN: Series solution, Eq. 5.39, for transient conduction in a plane wall with convection.

FIND: Midplane ($x^*=0$) and surface ($x^*=1$) temperatures θ^* for $Fo=0.1$ and 1, using $Bi=0.1, 1$ and 10 with only the first four eigenvalues. Based upon these results, discuss the validity of the approximate solutions, Eqs. 5.40 and 5.41.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties.

ANALYSIS: The series solution, Eq. 5.39a, is of the form,

$$\theta^* = \sum_{n=1}^{\infty} C_n \exp(-\zeta_n^2 Fo) \cos(\zeta_n x^*)$$

where the eigenvalues, ζ_n , and the constants, C_n , are from Eqs. 5.39b and 5.39c.

$$\zeta_n \tan \zeta_n = Bi \quad C_n = 4 \sin \zeta_n / (2\zeta_n + \sin(2\zeta_n)).$$

The eigenvalues are tabulated in Appendix B.3; note, however, that ζ_1 and C_1 are available from Table 5.1. The values of ζ_n and C_n used to evaluate θ^* are as follows:

Bi	ζ_1	C_1	ζ_2	C_2	ζ_3	C_3	ζ_4	C_4
0.1	0.3111	1.0160	3.1731	-0.0197	6.2991	0.0050	9.4354	-0.0022
1	0.8603	1.1191	3.4256	-0.1517	6.4373	0.0466	9.5293	-0.0217
10	1.4289	1.2620	4.3058	-0.3934	7.2281	0.2104	10.2003	-0.1309

Using ζ_n and C_n values, the terms of θ^* , designated as θ_1^* , θ_2^* , θ_3^* and θ_4^* , are as follows:

Fo=0.1						
Bi=0.1		Bi=1.0		Bi=10		
x^*	0	1	0	1	0	1
θ_1^*	1.0062	0.9579	1.0393	0.6778	1.0289	0.1455
θ_2^*	-0.0072	0.0072	-0.0469	0.0450	-0.0616	0.0244
θ_3^*	0.0001	0.0001	0.0007	0.0007	0.0011	0.0006
θ_4^*	-2.99×10^{-7}	3.00×10^{-7}	2.47×10^{-6}	2.46×10^{-7}	-3.96×10^{-6}	2.83×10^{-6}

PROBLEM 5.34 (Cont.)

Fo=1						
x^*	Bi=0.1		Bi=1.0		Bi=10	
	0	1	0	1	0	1
θ_1^*	0.9223	0.8780	0.5339	0.3482	0.1638	0.0232
θ_2^*	8.35×10^{-7}	8.35×10^{-7}	-1.22×10^{-5}	1.17×10^{-6}	3.49×10^{-9}	1.38×10^{-9}
θ_3^*	7.04×10^{-20}	-	4.70×10^{-20}	-	4.30×10^{-24}	-
θ_4^*	4.77×10^{-42}	-	7.93×10^{-42}	-	8.52×10^{-47}	-
θ^*	0.9223	0.8780	0.5339	0.3482	0.1638	0.0232

The tabulated results for $\theta^* = \theta^*(x^*, \text{Bi}, \text{Fo})$ demonstrate that for Fo=1, the first eigenvalue is sufficient to accurately represent the series. However, for Fo=0.1, three eigenvalues are required for accurate representation.

A more detailed analysis would show that a practical criterion for representation of the series solution by one eigenvalue is Fo>0.2. For these situations the approximate solutions, Eqs. 5.40 and 5.41, are appropriate. For the midplane, $x^*=0$, the first two eigenvalues for Fo=0.2 are:

Bi	Fo=0.2 $x^*=0$		
	0.1	1.0	10
θ_1^*	0.9965	0.9651	0.8389
θ_2^*	-0.00226	-0.0145	-0.0096
θ^*	0.9939	0.9506	0.8293
Error, %	+0.26	+1.53	+1.16

The percentage error shown in the last row of the above table is due to the effect of the second term. For Bi=0.1, neglecting the second term provides an error of 0.26%. For Bi=1, the error is 1.53%.

Hence we conclude that the approximate series solutions (with only one eigenvalue) provides systematically high results, but by less than 1.5%, for the Biot number range from 0.1 to 10.

PROBLEM 5.35

KNOWN: One-dimensional wall, initially at a uniform temperature, T_i , is suddenly exposed to a convection process (T_∞, h). For wall #1, the time ($t_1 = 100\text{s}$) required to reach a specified temperature at $x = L$ is prescribed, $T(L_1, t_1) = 315^\circ\text{C}$.

FIND: For wall #2 of different thickness and thermal conditions, the time, t_2 , required for $T(L_2, t_2) = 28^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: The properties, thickness and thermal conditions for the two walls are:

Wall	$L(\text{m})$	$\alpha(\text{m}^2/\text{s})$	$k(\text{W/m}\cdot\text{K})$	$T_i(^{\circ}\text{C})$	$T_\infty(^{\circ}\text{C})$	$h(\text{W/m}^2\cdot\text{K})$
1	0.10	15×10^{-6}	50	300	400	200
2	0.40	25×10^{-6}	100	30	20	100

The dimensionless functional dependence for the one-dimensional, transient temperature distribution, Eq. 5.38, is

$$\theta^* = \frac{T(x, t) - T_\infty}{T_i - T_\infty} = f(x^*, \text{Bi}, \text{Fo})$$

where

$$x^* = x/L \quad \text{Bi} = hL/k \quad \text{Fo} = \alpha t/L^2.$$

If the parameters x^* , Bi , and Fo are the same for both walls, then $\theta_1^* = \theta_2^*$. Evaluate these parameters:

Wall	x^*	Bi	Fo	θ^*
1	1	0.40	0.150	0.85
2	1	0.40	$1.563 \times 10^{-4} t_2$	0.85

where

$$\theta_1^* = \frac{315 - 400}{300 - 400} = 0.85 \quad \theta_2^* = \frac{28.5 - 20}{30 - 20} = 0.85.$$

It follows that

$$\text{Fo}_2 = \text{Fo}_1 \quad 1.563 \times 10^{-4} t_2 = 0.150$$

$$t_2 = 960\text{s}.$$

<

PROBLEM 5.36

KNOWN: The chuck of a semiconductor processing tool, initially at a uniform temperature of $T_i = 100^\circ\text{C}$, is cooled on its top surface by supply air at 20°C with a convection coefficient of $50 \text{ W/m}^2\cdot\text{K}$.

FIND: (a) Time required for the lower surface to reach 25°C , and (b) Compute and plot the time-to-cool as a function of the convection coefficient for the range $10 \leq h \leq 2000 \text{ W/m}^2\cdot\text{K}$; comment on the effectiveness of the head design as a method for cooling the chuck.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in the chuck, (2) Lower surface is perfectly insulated, (3) Uniform convection coefficient and air temperature over the upper surface of the chuck, and (4) Constant properties.

PROPERTIES: Table A.1, Aluminum alloy 2024 ($(25 + 100)^\circ\text{C} / 2 = 335 \text{ K}$): $\rho = 2770 \text{ kg/m}^3$, $c_p = 880 \text{ J/kg}\cdot\text{K}$, $k = 179 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) The Biot number for the chuck with $h = 50 \text{ W/m}^2\cdot\text{K}$ is

$$\text{Bi} = \frac{hL}{k} = \frac{50 \text{ W/m}^2\cdot\text{K} \times 0.025 \text{ m}}{179 \text{ W/m}\cdot\text{K}} = 0.007 \leq 0.1 \quad (1)$$

so that the lumped capacitance method is appropriate. Using Eq. 5.5, with $V/A_s = L$,

$$t = \frac{Vc}{hA_s} \ln \frac{\theta}{\theta_i} \quad \theta = T - T_\infty \quad \theta_i = T_i - T_\infty$$

$$t = \left(2770 \text{ kg/m}^3 \times 0.025 \text{ m} \times 880 \text{ J/kg}\cdot\text{K} / 50 \text{ W/m}^2\cdot\text{K} \right) \ln \frac{(100 - 20)^\circ\text{C}}{(25 - 20)^\circ\text{C}}$$

$$t = 3379 \text{ s} = 56.3 \text{ min}$$

<

Continued...

PROBLEM 5.36 (Cont.)

(b) When $h = 2000 \text{ W/m}^2\cdot\text{K}$, using Eq. (1), find $Bi = 0.28 > 0.1$ so that the series solution, Section 5.5.1, for the plane wall with convection must be used. Using the *IHT Transient Conduction, Plane Wall Model*, the time-to-cool was calculated as a function of the convection coefficient. Free convection cooling condition corresponds to $h \approx 10 \text{ W/m}^2\cdot\text{K}$ and the time-to-cool is 282 minutes. With the cooling head design, the time-to-cool can be substantially decreased if the convection coefficient can be increased as shown below.

PROBLEM 5.37

KNOWN: Thickness, properties and initial temperature of steel slab. Convection conditions.

FIND: Heating time required to achieve a minimum temperature of 550°C in the slab.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible radiation effects, (3) Constant properties.

ANALYSIS: With a Biot number of $hL/k = (250 \text{ W/m}^2 \cdot \text{K} \times 0.05 \text{ m})/48 \text{ W/m-K} = 0.260$, a lumped capacitance analysis should not be performed. At any time during heating, the lowest temperature in the slab is at the midplane, and from the one-term approximation to the transient thermal response of a plane wall, Eq. (5.41), we obtain

$$\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = \frac{(550 - 800)^\circ\text{C}}{(200 - 800)^\circ\text{C}} = 0.417 = C_1 \exp(-\zeta_1^2 \text{Fo})$$

With $\zeta_1 \approx 0.488 \text{ rad}$ and $C_1 \approx 1.0396$ from Table 5.1 and $\alpha = k / \rho c = 1.115 \times 10^{-5} \text{ m}^2 / \text{s}$,

$$-\zeta_1^2 \left(\alpha t / L^2 \right) = \ln(0.401) = -0.914$$

$$t = \frac{0.914 L^2}{\zeta_1^2 \alpha} = \frac{0.841 (0.05 \text{ m})^2}{(0.488)^2 1.115 \times 10^{-5} \text{ m}^2 / \text{s}} = 861 \text{ s}$$

<

COMMENTS: The surface temperature at $t = 861 \text{ s}$ may be obtained from Eq. (5.40b), where

$$\theta^* = \theta_o^* \cos(\zeta_1 x^*) = 0.417 \cos(0.488 \text{ rad}) = 0.368. \text{ Hence, } T(L, 792 \text{ s}) \equiv T_s = T_\infty + 0.368(T_i - T_\infty)$$

$= 800^\circ\text{C} - 221^\circ\text{C} = 579^\circ\text{C}$. Assuming a surface emissivity of $\varepsilon = 1$ and surroundings that are at $T_{\text{sur}} = T_\infty = 800^\circ\text{C}$, the radiation heat transfer coefficient corresponding to this surface temperature is

$$h_r = \varepsilon \sigma (T_s + T_{\text{sur}}) (T_s^2 + T_{\text{sur}}^2) = 205 \text{ W/m}^2 \cdot \text{K}. \text{ Since this value is comparable to the convection}$$

coefficient, radiation is not negligible and the desired heating will occur well before $t = 861 \text{ s}$.

PROBLEM 5.38

KNOWN: Pipe wall subjected to sudden change in convective surface condition. See Example 5.4.

FIND: (a) Temperature of the inner and outer surface of the pipe, heat flux at the inner surface, and energy transferred to the wall after 8 min; compare results to the hand calculations performed for the Text Example; (b) Time at which the outer surface temperature of the pipe, $T(0,t)$, will reach 25°C ; (c) Calculate and plot on a single graph the temperature distributions, $T(x,t)$ vs. x , for the initial condition, the final condition and the intermediate times of 4 and 8 min; explain key features; (d) Calculate and plot the temperature-time history, $T(x,t)$ vs. t , for the locations at the inner and outer pipe surfaces, $x = 0$ and L , and for the range $0 \leq t \leq 16$ min. Use the *IHT / Models / Transient Conduction / Plane Wall* model as the solution tool.

SCHEMATIC:

ASSUMPTIONS: (1) Pipe wall can be approximated as a plane wall, (2) Constant properties, (3) Outer surface of pipe is adiabatic.

ANALYSIS: The IHT model represents the series solution for the plane wall providing temperatures and heat fluxes evaluated at (x,t) and the total energy transferred at the inner wall at (t) . Selected portions of the IHT code used to obtain the results tabulated below are shown in the Comments.

(a) The code is used to evaluate the tabulated parameters at $t = 8$ min for locations $x = 0$ and L . The agreement is very good between the one-term approximation of the Example and the multiple-term series solution provided by the IHT model.

	Text Ex 5.4	IHT Model
$T(L, 8 \text{ min}), ^\circ\text{C}$	45.2	45.4
$T(0, 8 \text{ min}), ^\circ\text{C}$	42.9	43.1
$Q'(8 \text{ min}) \times 10^{-7}, \text{ J/m}$	-2.73	-2.72
$q_x''(L, 8 \text{ min}), \text{ W/m}^2$	-7400	-7305

(b) To determine the time t_0 for which $T(0,t) = 25^\circ\text{C}$, the IHT model is solved for t_0 after setting $x = 0$ and $T_{\text{xt}} = 25^\circ\text{C}$. Find, $t_0 = 4.4$ min. <

(c) The temperature distributions, $T(x,t)$ vs x , for the initial condition ($t = 0$), final condition ($t \rightarrow \infty$) and intermediate times of 4 and 8 min. are shown on the graph below.

Continued

PROBLEM 5.38 (Cont.)

The final condition corresponds to the steady-state temperature, $T(x, \infty) = T_{\infty}$. For the intermediate times, the gradient is zero at the insulated boundary ($x = 0$, the pipe exterior). As expected, the temperature at $x = 0$ will be less than at the boundary experiencing the convection process with the hot oil, $x = L$. Note, however, that the difference is not very significant. The gradient at the inner wall, $x = L$, decreases with increasing time.

(d) The temperature history $T(x, t)$ for the locations at the inner and outer pipe surfaces are shown in the graph below. Note that the temperature difference between the two locations is greatest at the start of the transient process and decreases with increasing time. After a 16 min. duration, the pipe temperature is almost uniform, but yet 3 or 4°C from the steady-state condition.

COMMENTS: (1) Selected portions of the IHT code for the plane wall model are shown below. Note the relation for the pipe volume, vol , used in calculating the total heat transferred per unit length over the time interval t .

```
// Models | Transient Conduction | Plane Wall
// The temperature distribution is
T_xt = T_xt_trans("Plane Wall", xstar, Fo, Bi, Ti, Tinf) // Eq 5.39
//T_xt = 25 // Part (b) surface temperature, x = 0
// The heat flux in the x direction is
q'_xt = qdprime_xt_trans("Plane Wall", x, L, Fo, Bi, k, Ti, Tinf) // Eq 2.6

// The total heat transfer from the wall over the time interval t is
QoverQo = Q_over_Qo_trans("Plane Wall", Fo, Bi) // Eq 5.45
Qo = rho * cp * vol * (Ti - Tinf) // Eq 5.44
//vol = 2 * As * L // Appropriate for wall of 2L thickness
vol = pi * D * L // Pipe wall of diameter D, thickness L and unit length
Q = QoverQo * Qo // Total energy transferred per unit length
```

(2) Can you give an explanation for why the inner and outer surface temperatures are not very different? What parameter provides a measure of the temperature non-uniformity in a system during a transient conduction process?

PROBLEM 5.39

KNOWN: Thickness, initial temperature and properties of furnace wall. Convection conditions at inner surface.

FIND: Time required for outer surface to reach a prescribed temperature. Corresponding temperature distribution in wall and at intermediate times.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in a plane wall, (2) Constant properties, (3) Adiabatic outer surface, (4) $Fo > 0.2$, (5) Negligible radiation from combustion gases.

ANALYSIS: The wall is equivalent to one-half of a wall of thickness $2L$ with symmetric convection conditions at its two surfaces. With $Bi = hL/k = 100 \text{ W/m}^2\cdot\text{K} \times 0.15\text{m}/1.5 \text{ W/m}\cdot\text{K} = 10$ and $Fo > 0.2$, the one-term approximation, Eq. 5.41 may be used to compute the desired time, where

$\theta_o^* = (T_o - T_\infty)/(T_i - T_\infty) = 0.215$. From Table 5.1, $C_1 = 1.262$ and $\zeta_1 = 1.4289$. Hence,

$$Fo = -\frac{\ln(\theta_o^*/C_1)}{\zeta_1^2} = -\frac{\ln(0.215/1.262)}{(1.4289)^2} = 0.867$$

$$t = \frac{Fo L^2}{\alpha} = \frac{0.867(0.15\text{m})^2}{(1.5 \text{ W/m}\cdot\text{K} / 2600 \text{ kg/m}^3 \times 1000 \text{ J/kg}\cdot\text{K})} = 33,800 \text{ s} \quad <$$

The corresponding temperature distribution, as well as distributions at $t = 0, 10,000$, and $20,000$ s are plotted below

COMMENTS: Because $Bi \gg 1$, the temperature at the inner surface of the wall increases much more rapidly than at locations within the wall, where temperature gradients are large. The temperature gradients decrease as the wall approaches a steady-state for which there is a uniform temperature of 950°C .

PROBLEM 5.40

KNOWN: Thickness, initial temperature and properties of steel plate. Convection conditions at both surfaces.

FIND: Time required to achieve a minimum temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in plate, (2) Symmetric heating on both sides, (3) Constant properties, (4) Negligible radiation from gases, (5) $Fo > 0.2$.

ANALYSIS: The smallest temperature exists at the midplane and, with $Bi = hL/k = 500 \text{ W/m}^2\cdot\text{K} \times 0.050\text{m}/45 \text{ W/m}\cdot\text{K} = 0.556$ and $Fo > 0.2$, may be determined from the one-term approximation of Eq. 5.41. From Table 5.1, $C_1 = 1.076$ and $\zeta_1 = 0.682$. Hence, with $\theta_o^* = (T_o - T_\infty)/(T_i - T_\infty) = 0.375$,

$$Fo = -\frac{\ln(\theta_o^*/C_1)}{\zeta_1^2} = -\frac{\ln(0.375/1.076)}{(0.682)^2} = 2.266$$

$$t = \frac{Fo L^2}{\alpha} = \frac{2.266(0.05\text{m})^2}{\left(45 \text{ W/m}\cdot\text{K} / 7800 \text{ kg/m}^3 \times 500 \text{ J/kg}\cdot\text{K}\right)} = 491 \text{ s} \quad <$$

COMMENTS: From Eq. 5.40b, the corresponding surface temperature is

$$T_s = T_\infty + (T_i - T_\infty)\theta_o^* \cos(\zeta_1) = 700^\circ\text{C} - 400^\circ\text{C} \times 0.375 \times 0.776 = 584^\circ\text{C}$$

Because Bi is not much larger than 0.1, temperature gradients in the steel are moderate.

PROBLEM 5.41

KNOWN: Plate of thickness $2L = 25$ mm at a uniform temperature of 600°C is removed from a hot pressing operation. Case 1, cooled on both sides; case 2, cooled on one side only.

FIND: (a) Calculate and plot on one graph the temperature histories for cases 1 and 2 for a 500-second cooling period; use the *IHT* software; Compare times required for the maximum temperature in the plate to reach 100°C ; and (b) For both cases, calculate and plot on one graph, the variation with time of the maximum temperature difference in the plate; Comment on the relative magnitudes of the temperature gradients within the plate as a function of time.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the plate, (2) Constant properties, and (3) For case 2, with cooling on one side only, the other side is adiabatic.

PROPERTIES: Plate (*given*): $\rho = 3000 \text{ kg/m}^3$, $c = 750 \text{ J/kg}\cdot\text{K}$, $k = 15 \text{ W/m}\cdot\text{K}$.

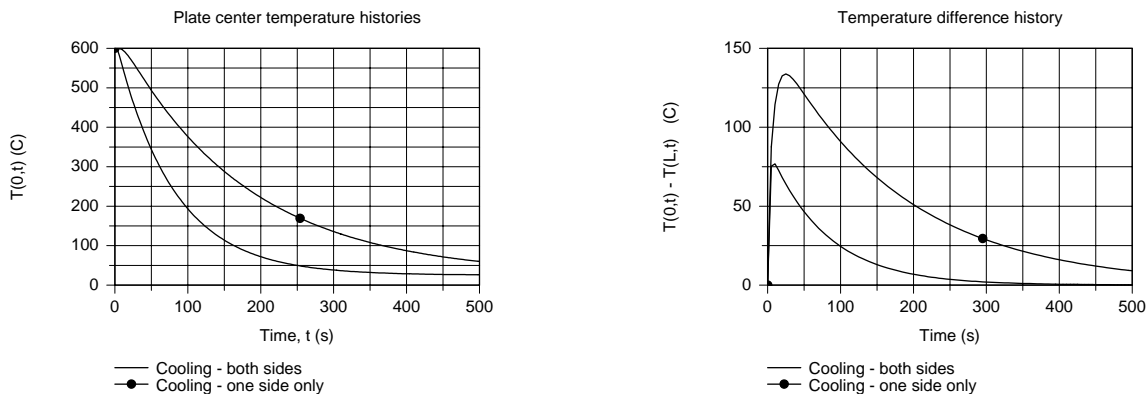

ANALYSIS: (a) From *IHT*, call up *Plane Wall, Transient Conduction* from the *Models* menu. For case 1, the plate thickness is 25 mm; for case 2, the plate thickness is 50 mm. The plate center ($x = 0$) temperature histories are shown in the graph below. The times required for the center temperatures to reach 100°C are

$$t_1 = 164 \text{ s}$$

$$t_2 = 367 \text{ s}$$

<

(b) The plot of $T(0, t) - T(1, t)$, which represents the maximum temperature difference in the plate during the cooling process, is shown below.

COMMENTS: (1) From the plate center-temperature history graph, note that it takes more than twice as long for the maximum temperature to reach 100°C with cooling on only one side.

(2) From the maximum temperature-difference graph, as expected, cooling from one side creates a larger maximum temperature difference during the cooling process. The effect could cause microstructure differences, which could adversely affect the mechanical properties within the plate.

PROBLEM 5.42

KNOWN: Properties and thickness L of ceramic coating on rocket nozzle wall. Convection conditions. Initial temperature and maximum allowable wall temperature.

FIND: (a) Maximum allowable engine operating time, t_{\max} , for $L = 10$ mm, (b) Coating inner and outer surface temperature histories for $L = 10$ and 40 mm.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in a plane wall, (2) Constant properties, (3) Negligible thermal capacitance of metal wall and heat loss through back surface, (4) Negligible contact resistance at wall/ceramic interface, (5) Negligible radiation.

ANALYSIS: (a) Subject to assumptions (3) and (4), the maximum wall temperature corresponds to the ceramic temperature at $x = 0$. Hence, for the ceramic, we wish to determine the time t_{\max} at which $T(0,t) = T_o(t) = 1500$ K. With $Bi = hL/k = 5000 \text{ W/m}^2 \cdot \text{K}(0.01 \text{ m})/10 \text{ W/m} \cdot \text{K} = 5$, the lumped capacitance method cannot be used. Assuming $Fo > 0.2$, obtaining $\zeta_1 = 1.3138$ and $C_1 = 1.2402$ from Table 5.1, and evaluating $\theta_o^* = (T_o - T_\infty)/(T_i - T_\infty) = 0.4$, Equation 5.41 yields

$$Fo = -\frac{\ln(\theta_o^*/C_1)}{\zeta_1^2} = -\frac{\ln(0.4/1.2402)}{(1.3138)^2} = 0.656$$

confirming the assumption of $Fo > 0.2$. Hence,

$$t_{\max} = \frac{Fo(L^2)}{\alpha} = \frac{0.656(0.01\text{m})^2}{6 \times 10^{-6} \text{ m}^2/\text{s}} = 10.9 \text{ s}$$

<

(b) Using the IHT *Lumped Capacitance Model for a Plane Wall*, the inner and outer surface temperature histories were computed and are as follows:

Continued...

PROBLEM 5.42 (Cont.)

The increase in the inner ($x = 0$) surface temperature lags that of the outer surface, but within $t \approx 45$ s both temperatures are within a few degrees of the gas temperature for $L = 0.01$ m. For $L = 0.04$ m, the increased thermal capacitance of the ceramic slows the approach to steady-state conditions. The thermal response of the inner surface significantly lags that of the outer surface, and it is not until $t \approx 137$ s that the inner surface reaches 1500 K. At this time there is still a significant temperature difference across the ceramic, with $T(L, t_{\max}) = 2240$ K.

COMMENTS: The allowable engine operating time increases with increasing thermal capacitance of the ceramic and hence with increasing L .

PROBLEM 5.43

KNOWN: Initial temperature, thickness and thermal diffusivity of glass plate. Prescribed surface temperature.

FIND: (a) Time to achieve 50% reduction in midplane temperature, (b) Maximum temperature gradient at that time.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: Prescribed surface temperature is analogous to $h \rightarrow \infty$ and $T_\infty = T_s$. Hence, $Bi = \infty$. Assume validity of one-term approximation to series solution for $T(x, t)$.

(a) At the midplane,

$$\theta_0^* = \frac{T_0 - T_s}{T_i - T_s} = 0.50 = C_1 \exp(-\zeta_1^2 Fo)$$

$$\zeta_1 \tan \zeta_1 = Bi = \infty \rightarrow \zeta_1 = \pi/2.$$

Hence

$$C_1 = \frac{4 \sin \zeta_1}{2 \zeta_1 + \sin(2 \zeta_1)} = \frac{4}{\pi} = 1.273$$

$$Fo = -\frac{\ln(\theta_0^*/C_1)}{\zeta_1^2} = 0.379$$

$$t = \frac{Fo L^2}{\alpha} = \frac{0.379 (0.01 \text{ m})^2}{6 \times 10^{-7} \text{ m}^2/\text{s}} = 63 \text{ s.}$$

<

(b) With $\theta^* = C_1 \exp(-\zeta_1^2 Fo) \cos \zeta_1 x^*$

$$\frac{\partial T}{\partial x} = \frac{(T_i - T_s)}{L} \frac{\partial \theta^*}{\partial x^*} = -\frac{(T_i - T_s)}{L} \zeta_1 C_1 \exp(-\zeta_1^2 Fo) \sin \zeta_1 x^*$$

$$\left. \frac{\partial T}{\partial x} \right|_{\max} = \left. \frac{\partial T}{\partial x} \right|_{x^*=1} = -\frac{300^\circ\text{C}}{0.01 \text{ m}} \frac{\pi}{2} 0.5 = -2.36 \times 10^4 \text{ }^\circ\text{C/m.}$$

<

COMMENTS: Validity of one-term approximation is confirmed by $Fo > 0.2$.

PROBLEM 5.44

KNOWN: Thickness and properties of rubber tire. Convection heating conditions. Initial and final midplane temperature.

FIND: (a) Time to reach final midplane temperature. (b) Effect of accelerated heating.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in a plane wall, (2) Constant properties, (3) Negligible radiation.

ANALYSIS: (a) With $Bi = hL/k = 200 \text{ W/m}^2\cdot\text{K}(0.01 \text{ m})/0.14 \text{ W/m}\cdot\text{K} = 14.3$, the lumped capacitance method is clearly inappropriate. Assuming $Fo > 0.2$, Eq. (5.41) may be used with $C_1 = 1.265$ and $\zeta_1 \approx 1.458 \text{ rad}$ from Table 5.1 to obtain

$$\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = C_1 \exp(-\zeta_1^2 Fo) = 1.265 \exp(-2.126 Fo)$$

With $\theta_o^* = (T_o - T_\infty)/(T_i - T_\infty) = (-50)/(-175) = 0.286$, $Fo = -\ln(0.286/1.265)/2.126 = 0.70 = \alpha t_f / L^2$

$$t_f = \frac{0.7(0.01 \text{ m})^2}{6.35 \times 10^{-8} \text{ m}^2/\text{s}} = 1100 \text{ s}$$

<

(b) The desired temperature histories were generated using the IHT *Transient Conduction Model* for a *Plane Wall*, with $h = 5 \times 10^4 \text{ W/m}^2\cdot\text{K}$ used to approximate imposition of a surface temperature of 200°C .

The fact that imposition of a constant surface temperature ($h \rightarrow \infty$) does not significantly accelerate the heating process should not be surprising. For $h = 200 \text{ W/m}^2\cdot\text{K}$, the Biot number is already quite large ($Bi = 14.3$), and limits to the heating rate are principally due to conduction in the rubber and not to convection at the surface. Any increase in h only serves to reduce what is already a small component of the total thermal resistance.

COMMENTS: The heating rate could be accelerated by increasing the steam temperature, but an upper limit would be associated with avoiding thermal damage to the rubber.

PROBLEM 5.45

KNOWN: Stack or book comprised of 11 metal plates (p) and 10 boards (b) each of 2.36 mm thickness and prescribed thermophysical properties.

FIND: Effective thermal conductivity, k , and effective thermal capacitance, (ρc_p) .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible contact resistance between plates and boards.

PROPERTIES: Metal plate (p, given): $\rho_p = 8000 \text{ kg/m}^3$, $c_{p,p} = 480 \text{ J/kg}\cdot\text{K}$, $k_p = 12 \text{ W/m}\cdot\text{K}$; Circuit boards (b, given): $\rho_b = 1000 \text{ kg/m}^3$, $c_{p,b} = 1500 \text{ J/kg}\cdot\text{K}$, $k_b = 0.30 \text{ W/m}\cdot\text{K}$.

ANALYSIS: The thermal resistance of the book is determined as the sum of the resistance of the boards and plates,

$$R''_{\text{tot}} = NR''_b + MR''_p$$

where M, N are the number of plates and boards in the book, respectively, and $R''_i = L_i / k_i$ where L_i and k_i are the thickness and thermal conductivities, respectively.

$$\begin{aligned} R''_{\text{tot}} &= M(L_p / k_p) + N(L_b / k_b) \\ R''_{\text{tot}} &= 11(0.00236 \text{ m} / 12 \text{ W/m}\cdot\text{K}) + 10(0.00236 \text{ m} / 0.30 \text{ W/m}\cdot\text{K}) \\ R''_{\text{tot}} &= 2.163 \times 10^{-3} + 7.867 \times 10^{-2} = 8.083 \times 10^{-2} \text{ K/W} \end{aligned}$$

The effective thermal conductivity of the book of thickness $(10 + 11) 2.36 \text{ mm}$ is

$$k = L / R''_{\text{tot}} = \frac{0.04956 \text{ m}}{8.083 \times 10^{-2} \text{ K/W}} = 0.613 \text{ W/m}\cdot\text{K}. \quad <$$

The thermal capacitance of the stack is

$$\begin{aligned} C''_{\text{tot}} &= M(\rho_p L_p c_p) + N(\rho_b L_b c_b) \\ C''_{\text{tot}} &= 11(8000 \text{ kg/m}^3 \times 0.00236 \text{ m} \times 480 \text{ J/kg}\cdot\text{K}) + 10(1000 \text{ kg/m}^3 \times 0.00236 \text{ m} \times 1500 \text{ J/kg}\cdot\text{K}) \\ C''_{\text{tot}} &= 9.969 \times 10^4 + 3.540 \times 10^4 = 1.35 \times 10^5 \text{ J/m}^2 \cdot \text{K} \end{aligned}$$

The effective thermal capacitance of the book is

$$(\rho c_p) = C''_{\text{tot}} / L = 1.351 \times 10^5 \text{ J/m}^2 \cdot \text{K} / 0.04956 \text{ m} = 2.726 \times 10^6 \text{ J/m}^3 \cdot \text{K}. \quad <$$

COMMENTS: The results of the analysis allow for representing the stack as a homogeneous medium with *effective* properties: $k = 0.613 \text{ W/m}\cdot\text{K}$ and $\alpha = (k/\rho c_p) = 2.249 \times 10^{-7} \text{ m}^2/\text{s}$. See for example, Problem 5.41.

PROBLEM 5.46

KNOWN: Stack of circuit board-pressing plates, initially at a uniform temperature, is subjected by upper/lower platens to a higher temperature.

FIND: (a) Elapsed time, t_e , required for the mid-plane to reach cure temperature when platens are suddenly changed to $T_s = 190^\circ\text{C}$, (b) Energy removal from the stack needed to return its temperature to T_i .

SCHEMATIC:

PROPERTIES: Stack (given): $k = 0.613 \text{ W/m}\cdot\text{K}$, $\rho c_p = 2.73 \times 10^6 \text{ J/m}^3 \cdot \text{K}$; $\alpha = k/\rho c_p = 2.245 \times 10^{-7} \text{ m}^2/\text{s}$.

ANALYSIS: (a) Recognize that sudden application of surface temperature corresponds to $h \rightarrow \infty$, or $\text{Bi} \rightarrow \infty$. With $T_s = T_\infty$,

$$\theta_o^* = \frac{T(0,t) - T_s}{T_i - T_s} = \frac{(170 - 190)^\circ\text{C}}{(15 - 190)^\circ\text{C}} = 0.114.$$

Using Eq. 5.41 with values of $\zeta_1 = 1.5707$ and $C_1 = 1.2733$ for $\text{Bi} \rightarrow \infty$ (Table 5.1), find Fo

$$\theta_o^* = C_1 \exp(-\zeta_1^2 \text{Fo})$$

$$\text{Fo} = -\frac{1}{\zeta_1^2} \ln(\theta_o^*/C_1) = -\frac{1}{(1.5707)^2} \ln(0.114/1.2733) = 0.977$$

where $\text{Fo} = \alpha t/L^2$,

$$t = \frac{\text{Fo} L^2}{\alpha} = \frac{0.977 (25 \times 10^{-3} \text{ m})^2}{2.245 \times 10^{-7} \text{ m}^2/\text{s}} = 2.720 \times 10^3 \text{ s} = 45.3 \text{ min.} \quad <$$

(b) The energy removal is equivalent to the energy gained by the stack per unit area for the time interval $0 \rightarrow t_e$. With Q_o'' corresponding to the maximum amount of energy that could be transferred,

$$Q_o'' = \rho c (2L)(T_i - T_\infty) = 2.73 \times 10^6 \text{ J/m}^3 \cdot \text{K} (2 \times 25 \times 10^{-3} \text{ m}) (15 - 190) \text{ K} = -2.389 \times 10^7 \text{ J/m}^2.$$

Q'' may be determined from Eq. 5.46,

$$\frac{Q''}{Q_o''} = 1 - \frac{\sin \zeta_1}{\zeta_1} \theta_o^* = 1 - \frac{\sin(1.5707 \text{ rad})}{1.5707 \text{ rad}} \times 0.114 = 0.927$$

We conclude that the energy to be removed from the stack per unit area to return it to T_i is

$$Q'' = 0.927 Q_o'' = 0.927 \times 2.389 \times 10^7 \text{ J/m}^2 = 2.21 \times 10^7 \text{ J/m}^2. \quad <$$

PROBLEM 5.47

KNOWN: Thickness, initial temperature and properties of plastic coating. Safe-to-touch temperature. Convection coefficient and air temperature.

FIND: Time for surface to reach safe-to-touch temperature. Corresponding temperature at plastic/wood interface.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in coating, (2) Negligible radiation, (3) Constant properties, (4) Negligible heat of reaction, (5) Negligible heat transfer across plastic/wood interface.

ANALYSIS: With $Bi = hL/k = 200 \text{ W/m}^2 \cdot \text{K} \times 0.002 \text{ m} / 0.25 \text{ W/m} \cdot \text{K} = 1.6 > 0.1$, the lumped capacitance method may not be used. Applying the approximate solution of Eq. 5.40a, with $C_1 = 1.155$ and $\zeta_1 = 0.990$ from Table 5.1,

$$\theta_s^* = \frac{T_s - T_\infty}{T_i - T_\infty} = \frac{(42 - 25)^\circ\text{C}}{(200 - 25)^\circ\text{C}} = 0.0971 = C_1 \exp(-\zeta_1^2 Fo) \cos(\zeta_1 x^*) = 1.155 \exp(-0.980 Fo) \cos(0.99)$$

Hence, for $x^* = 1$,

$$Fo = -\ln\left(\frac{0.0971}{1.155 \cos(0.99)}\right) / (0.99)^2 = 1.914$$

$$t = \frac{Fo L^2}{\alpha} = \frac{1.914 (0.002 \text{ m})^2}{1.20 \times 10^{-7} \text{ m}^2/\text{s}} = 63.8 \text{ s} \quad <$$

From Eq. 5.41, the corresponding interface temperature is

$$T_o = T_\infty + (T_i - T_\infty) \exp(-\zeta_1^2 Fo) = 25^\circ\text{C} + 175^\circ\text{C} \exp(-0.98 \times 1.914) = 51.8^\circ\text{C} \quad <$$

COMMENTS: By neglecting conduction into the wood and radiation from the surface, the cooling time is overpredicted and is therefore a conservative estimate. However, if energy generation due to solidification of polymer were significant, the cooling time would be longer.

PROBLEM 5.48

KNOWN: Long rod with prescribed diameter and properties, initially at a uniform temperature, is heated in a forced convection furnace maintained at 750 K with a convection coefficient of $h = 1000 \text{ W/m}^2 \cdot \text{K}$.

FIND: (a) The corresponding center temperature of the rod, $T(0, t_o)$, when the surface temperature $T(r_o, t_o)$ is measured as 550 K, (b) Effect of h on centerline temperature history.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction in rod, (2) Constant properties, (3) Rod, when initially placed in furnace, had a uniform (but unknown) temperature, (4) $Fo \geq 0.2$.

ANALYSIS: (a) Since the rod was initially at a uniform temperature and $Fo \geq 0.2$, the approximate solution for the infinite cylinder is appropriate. From Eq. 5.49b,

$$\theta^*(r^*, Fo) = \theta_o^*(Fo) J_0(\zeta_1 r^*) \quad (1)$$

where, for $r^* = 1$, the dimensionless temperatures are, from Eq. 5.31,

$$\theta^*(1, Fo) = \frac{T(r_o, t_o) - T_\infty}{T_i - T_\infty} \quad \theta_o^*(Fo) = \frac{T(0, t_o) - T_\infty}{T_i - T_\infty} \quad (2,3)$$

Combining Eqs. (2) and (3) with Eq. (1) and rearranging,

$$\begin{aligned} \frac{T(r_o, t_o) - T_\infty}{T_i - T_\infty} &= \frac{T(0, t_o) - T_\infty}{T_i - T_\infty} J_0(\zeta_1 \cdot 1) \\ T(0, t_o) &= T_\infty + \frac{1}{J_0(\zeta_1)} [T(r_o, t_o) - T_\infty] \end{aligned} \quad (4)$$

The eigenvalue, $\zeta_1 = 1.0185 \text{ rad}$, follows from Table 5.1 for the Biot number

$$Bi = \frac{hr_o}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} (0.060 \text{ m}/2)}{50 \text{ W/m} \cdot \text{K}} = 0.60.$$

From Table B-4, with $\zeta_1 = 1.0185 \text{ rad}$, $J_0(1.0185) = 0.7568$. Hence, from Eq. (4)

$$T(0, t_o) = 750 \text{ K} + \frac{1}{0.7568} [550 - 750] \text{ K} = 486 \text{ K} \quad <$$

(b) Using the IHT *Transient Conduction Model* for a *Cylinder*, the following temperature histories were generated.

Continued...

PROBLEM 5.48 (Cont.)

The times required to reach a centerline temperature of 500 K are 367, 85 and 51s, respectively, for $h = 100$, 500 and $1000 \text{ W/m}^2\cdot\text{K}$. The corresponding values of the Biot number are 0.06, 0.30 and 0.60. Hence, even for $h = 1000 \text{ W/m}^2\cdot\text{K}$, the convection resistance is not negligible relative to the conduction resistance and significant reductions in the heating time could still be effected by increasing h to values considerably in excess of $1000 \text{ W/m}^2\cdot\text{K}$.

COMMENTS: For Part (a), recognize why it is not necessary to know T_i or the time t_o . We require that $Fo \geq 0.2$, which for this sphere corresponds to $t \geq 14\text{s}$. For this situation, the time dependence of the surface and center are the same.

PROBLEM 5.49

KNOWN: A long cylinder, initially at a uniform temperature, is suddenly quenched in a large oil bath.

FIND: (a) Time required for the surface to reach 500 K, (b) Effect of convection coefficient on surface temperature history.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) $Bi > 0.2$.

ANALYSIS: (a) Check first whether lumped capacitance method is applicable. For $h = 50 \text{ W/m}^2 \cdot \text{K}$,

$$Bi_c = \frac{hL_c}{k} = \frac{h(r_o/2)}{k} = \frac{50 \text{ W/m}^2 \cdot \text{K} (0.015 \text{ m}/2)}{1.7 \text{ W/m} \cdot \text{K}} = 0.221.$$

Since $Bi_c > 0.1$, method is not suited. Using the approximate series solution for the infinite cylinder,

$$\theta^*(r^*, Fo) = C_1 \exp(-\zeta_1^2 Fo) \times J_0(\zeta_1 r^*) \quad (1)$$

Solving for Fo and setting $r^* = 1$, find

$$Fo = -\frac{1}{\zeta_1^2} \ln \left[\frac{\theta^*}{C_1 J_0(\zeta_1)} \right]$$

$$\text{where } \theta^* = (1, Fo) = \frac{T(r_o, t_o) - T_{\infty}}{T_i - T_{\infty}} = \frac{(500 - 350) \text{ K}}{(1000 - 350) \text{ K}} = 0.231.$$

From Table 5.1, with $Bi = 0.441$, find $\zeta_1 = 0.8882 \text{ rad}$ and $C_1 = 1.1019$. From Table B.4, find $J_0(\zeta_1) = 0.8121$. Substituting numerical values into Eq. (2),

$$Fo = -\frac{1}{(0.8882)^2} \ln [0.231/1.1019 \times 0.8121] = 1.72.$$

From the definition of the Fourier number, $Fo = \alpha t / r_o^2$, and $\alpha = k/\rho c$,

$$t = Fo \frac{r_o^2}{\alpha} = Fo \cdot r_o^2 \frac{c}{k}$$

$$t = 1.72 (0.015 \text{ m})^2 \times 400 \text{ kg/m}^3 \times 1600 \text{ J/kg} \cdot \text{K} / 1.7 \text{ W/m} \cdot \text{K} = 145 \text{ s}.$$

<

(b) Using the IHT *Transient Conduction Model* for a *Cylinder*, the following surface temperature histories were obtained.

Continued...

PROBLEM 5.49 (Cont.)

Increasing the convection coefficient by a factor of 5 has a significant effect on the surface temperature, greatly accelerating its approach to the oil temperature. However, even with $h = 250 \text{ W/m}^2\cdot\text{K}$, $Bi = 1.1$ and the convection resistance remains significant. Hence, in the interest of accelerated cooling, additional benefit could be achieved by further increasing the value of h .

COMMENTS: For Part (a), note that, since $Fo = 1.72 > 0.2$, the approximate series solution is appropriate.

PROBLEM 5.50

KNOWN: Long pyroceram rod, initially at a uniform temperature of 900 K, and clad with a thin metallic tube giving rise to a thermal contact resistance, is suddenly cooled by convection.

FIND: (a) Time required for rod centerline to reach 600 K, (b) Effect of convection coefficient on cooling rate.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Thermal resistance and capacitance of metal tube are negligible, (3) Constant properties, (4) $Fo \geq 0.2$.

PROPERTIES: Table A-2, Pyroceram ($\bar{T} = (600 + 900)\text{K}/2 = 750 \text{ K}$): $\rho = 2600 \text{ kg/m}^3$, $c = 1100 \text{ J/kg}\cdot\text{K}$, $k = 3.13 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) The thermal contact and convection resistances can be combined to give an overall heat transfer coefficient. Note that $R'_{t,c}$ [$\text{m}\cdot\text{K}/\text{W}$] is expressed per unit length for the outer surface. Hence, for $h = 100 \text{ W/m}^2\cdot\text{K}$,

$$U = \frac{1}{1/h + R'_{t,c}(\pi D)} = \frac{1}{1/100 \text{ W/m}^2\cdot\text{K} + 0.12 \text{ m}\cdot\text{K}/\text{W}(\pi \times 0.020 \text{ m})} = 57.0 \text{ W/m}^2\cdot\text{K}.$$

Using the approximate series solution, Eq. 5.49c, the Fourier number can be expressed as

$$Fo = -\left(1/\zeta_1^2\right) \ln\left(\theta_o^*/C_1\right).$$

From Table 5.1, find $\zeta_1 = 0.5884 \text{ rad}$ and $C_1 = 1.0441$ for

$$Bi = U r_o / k = 57.0 \text{ W/m}^2\cdot\text{K} (0.020 \text{ m}/2) / 3.13 \text{ W/m}\cdot\text{K} = 0.182.$$

The dimensionless temperature is

$$\theta_o^*(0, Fo) = \frac{T(0, t) - T_\infty}{T_i - T_\infty} = \frac{(600 - 300) \text{ K}}{(900 - 300) \text{ K}} = 0.5.$$

Substituting numerical values to find Fo and then the time t ,

$$Fo = \frac{-1}{(0.5884)^2} \ln \frac{0.5}{1.0441} = 2.127$$

$$t = Fo \frac{r_o^2}{\alpha} = Fo \cdot r_o^2 \frac{c}{k}$$

$$t = 2.127 (0.020 \text{ m}/2)^2 \frac{2600 \text{ kg/m}^3 \times 1100 \text{ J/kg}\cdot\text{K}}{3.13 \text{ W/m}\cdot\text{K}} = 194 \text{ s}.$$

<

(b) The following temperature histories were generated using the IHT *Transient conduction Model* for a *Cylinder*.

Continued...

PROBLEM 5.50 (Cont.)

While enhanced cooling is achieved by increasing h from 100 to 500 $\text{W/m}^2\cdot\text{K}$, there is little benefit associated with increasing h from 500 to 1000 $\text{W/m}^2\cdot\text{K}$. The reason is that for h much above 500 $\text{W/m}^2\cdot\text{K}$, the contact resistance becomes the dominant contribution to the total resistance between the fluid and the rod, rendering the effect of further reductions in the convection resistance negligible. Note that, for $h = 100, 500$ and $1000 \text{ W/m}^2\cdot\text{K}$, the corresponding values of U are 57.0, 104.8 and 117.1 $\text{W/m}^2\cdot\text{K}$, respectively.

COMMENTS: For Part (a), note that, since $Fo = 2.127 > 0.2$, Assumption (4) is satisfied.

PROBLEM 5.51

KNOWN: Sapphire rod, initially at a uniform temperature of 800 K is suddenly cooled by a convection process; after 35 s, the rod is wrapped in insulation.

FIND: Temperature rod reaches after a long time following the insulation wrap.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) No heat losses from the rod when insulation is applied.

PROPERTIES: Table A-2, Aluminum oxide, sapphire (550K): $\rho = 3970 \text{ kg/m}^3$, $c = 1068 \text{ J/kg} \cdot \text{K}$, $k = 22.3 \text{ W/m} \cdot \text{K}$, $\alpha = 5.259 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: First calculate the Biot number with $L_c = r_o/2$,

$$\text{Bi} = \frac{h L_c}{k} = \frac{h (r_o/2)}{k} = \frac{1600 \text{ W/m}^2 \cdot \text{K} (0.020 \text{ m}/2)}{22.3 \text{ W/m} \cdot \text{K}} = 0.72.$$

Since $\text{Bi} > 0.1$, the rod cannot be approximated as a lumped capacitance system. The temperature distribution during the cooling process, $0 \leq t \leq 35 \text{ s}$, and for the time following the application of insulation, $t > 35 \text{ s}$, will appear as

Eventually ($t \rightarrow \infty$), the temperature of the rod will be uniform at $\bar{T}(\infty)$.

We begin by determining the energy transferred from the rod at $t = 35 \text{ s}$. We have

$$\text{Bi} = \frac{h r_o}{k} = \frac{1600 \text{ W/m}^2 \cdot \text{K} \times 0.020 \text{ m}}{22.3 \text{ W/m} \cdot \text{K}} = 1.43$$

$$\text{Fo} = \alpha t / r_o^2 = 5.259 \times 10^{-6} \text{ m}^2/\text{s} \times 35 \text{ s} / (0.02 \text{ m})^2 = 0.46$$

Since $\text{Fo} > 0.2$, we can use the one-term approximation. From Table 5.1, $\zeta_1 = 1.4036 \text{ rad}$, $C_1 = 1.2636$. Then from Equation 5.49c,

$$\theta_o^* = C_1 \exp(-\zeta_1^2 \text{Fo}) = 1.2636 \exp(-1.4036^2 \times 0.46) = 0.766$$

and from Equation 5.51

Continued...

PROBLEM 5.51 (Cont.)

$$\frac{Q}{Q_o} = 1 - \frac{2\theta_o^*}{\zeta_1} J_1(\zeta_1) = 1 - \frac{2 \times 0.766}{1.4036} 0.5425 = 0.408$$

where $J_1(\zeta_1)$ was found from App. B.4. Since the rod is well insulated after $t = 35$ s, the energy transferred from the rod remains unchanged. To find $\bar{T}(\infty)$, write the conservation of energy requirement for the rod on a *time interval* basis, $E_{in} - E_{out} = \Delta E \equiv E_{final} - E_{initial}$. Using the nomenclature of Section 5.5.3 and basing energy relative to T_∞ , the energy balance becomes

$$-Q = \rho cV(\bar{T}(\infty) - T_\infty) - Q_o$$

where $Q_o = \rho cV(T_i - T_\infty)$. Dividing through by Q_o and solving for $\bar{T}(\infty)$, find

$$\bar{T}(\infty) = T_\infty + (T_i - T_\infty)(1 - Q/Q_o).$$

Hence,

$$\bar{T}(\infty) = 300\text{K} + (800 - 300)\text{K} (1 - 0.408) = 596 \text{ K.}$$

<

PROBLEM 5.52

KNOWN: Long plastic rod of diameter D heated uniformly in an oven to T_i and then allowed to convectively cool in ambient air (T_∞, h) for a 3 minute period. Minimum temperature of rod should not be less than 200°C and the maximum-minimum temperature within the rod should not exceed 10°C .

FIND: Initial uniform temperature T_i to which rod should be heated. Whether the 10°C internal temperature difference is exceeded.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) Uniform and constant convection coefficients.

PROPERTIES: Plastic rod (given): $k = 0.3 \text{ W/m}\cdot\text{K}$, $\rho c_p = 1040 \text{ kJ/m}^3\cdot\text{K}$.

ANALYSIS: For the worst case condition, the rod cools for 3 minutes and its outer surface is at least 200°C in order that the subsequent pressing operation will be satisfactory. Hence,

$$Bi = \frac{hr_o}{k} = \frac{8 \text{ W/m}^2\cdot\text{K} \times 0.015 \text{ m}}{0.3 \text{ W/m}\cdot\text{K}} = 0.40$$

$$Fo = \frac{\alpha t}{r_o^2} = \frac{k}{\rho c_p} \cdot \frac{t}{r_o^2} = \frac{0.3 \text{ W/m}\cdot\text{K}}{1040 \times 10^3 \text{ J/m}^3\cdot\text{K}} \times \frac{3 \times 60 \text{ s}}{(0.015 \text{ m})^2} = 0.2308.$$

Using Eq. 5.49a and $\zeta_1 = 0.8516 \text{ rad}$ and $C_1 = 1.0932$ from Table 5.1,

$$\theta^* = \frac{T(r_o, t) - T_\infty}{T_i - T_\infty} = C_1 J_0(\zeta_1 r_o^*) \exp(-\zeta_1^2 Fo).$$

With $r_o^* = 1$, from Table B.4, $J_0(\zeta_1 \times 1) = J_0(0.8516) = 0.8263$, giving

$$\frac{200 - 25}{T_i - 25} = 1.0932 \times 0.8263 \exp(-0.8516^2 \times 0.2308) \quad T_i = 254^\circ\text{C}. \quad <$$

At this time (3 minutes) what is the difference between the center and surface temperatures of the rod? From Eq. 5.49b,

$$\frac{\theta^*}{\theta_o} = \frac{T(r_o, t) - T_\infty}{T(0, t) - T_\infty} = \frac{200 - 25}{T(0, t) - 25} = J_0(\zeta_1 r_o^*) = 0.8263$$

which gives $T(0, t) = 237^\circ\text{C}$. Hence,

$$\Delta T = T(0, 180 \text{ s}) - T(r_o, 180 \text{ s}) = (237 - 200)^\circ\text{C} = 37^\circ\text{C}. \quad <$$

Hence, the desired max-min temperature difference sought (10°C) is not achieved.

COMMENTS: ΔT could be reduced by decreasing the cooling rate; however, h can not be made much smaller. Two solutions are (a) increase ambient air temperature and (b) non-uniformly heat rod in oven by controlling its residence time.

PROBLEM 5.53

KNOWN: Diameter and initial temperature of roller bearings. Temperature of oil bath and convection coefficient. Final centerline temperature. Number of bearings processed per hour.

FIND: Time required to reach centerline temperature. Cooling load.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction in rod, (2) Constant properties.

PROPERTIES: Table A.1, St. St. 304 ($\bar{T} = 548 \text{ K}$): $\rho = 7900 \text{ kg/m}^3$, $k = 19.0 \text{ W/m}\cdot\text{K}$, $c_p = 546 \text{ J/kg}\cdot\text{K}$, $\alpha = 4.40 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: With $Bi = h(r_o/2)/k = 0.658$, the lumped capacitance method can not be used. From the one-term approximation of Eq. 5.49 c for the centerline temperature,

$$\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = \frac{50 - 30}{500 - 30} = 0.0426 = C_1 \exp(-\zeta_1^2 Fo) = 1.1382 \exp[-(0.9287)^2 Fo]$$

where, for $Bi = hr_o/k = 1.316$, $C_1 = 1.2486$ and $\zeta_1 = 1.3643$ from Table 5.1.

$$Fo = -\ln(0.0341)/1.86 = 1.82$$

$$t_f = Fo r_o^2 / \alpha = 1.82(0.05 \text{ m})^2 / 4.40 \times 10^{-6} = 1031 \text{ s} = 17 \text{ min} \quad <$$

From Eqs. 5.44 and 5.51, the energy extracted from a single rod is

$$Q = \rho c V (T_i - T_\infty) \left[1 - \frac{2\theta_o^*}{\zeta_1} J_1(\zeta_1) \right]$$

With $J_1(1.3643) = 0.535$ from Table B.4,

$$Q = 7900 \text{ kg/m}^3 \times 546 \text{ J/kg}\cdot\text{K} \left[\pi (0.05 \text{ m})^2 1 \text{ m} \right] 470 \text{ K} \left[1 - \frac{0.0852 \times 0.535}{1.3643} \right] = 1.54 \times 10^7 \text{ J}$$

The nominal cooling load is

$$\bar{q} = \frac{NQ}{t_f} = \frac{10 \times 1.54 \times 10^7 \text{ J}}{1031 \text{ s}} = 1.49 \times 10^5 \text{ W} = 149 \text{ kW} \quad <$$

COMMENTS: For a centerline temperature of 50°C , Eq. 5.49b yields a surface temperature of

$$T(r_o, t) = T_\infty + (T_i - T_\infty) \theta_o^* J_o(\zeta_1) = 30^\circ\text{C} + 470^\circ\text{C} \times 0.0426 \times 0.586 = 41.7^\circ\text{C}$$

PROBLEM 5.54

KNOWN: Long rods of 40 mm- and 80-mm diameter at a uniform temperature of 400°C in a curing oven, are removed and cooled by forced convection with air at 25°C. The 40-mm diameter rod takes 280 s to reach a *safe-to-handle* temperature of 60°C.

FIND: Time it takes for a 80-mm diameter rod to cool to the same safe-to-handle temperature. Comment on the result? Did you anticipate this outcome?

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial (cylindrical) conduction in the rods, (2) Constant properties, and (3) Convection coefficient same value for both rods.

PROPERTIES: Rod (given): $\rho = 2500 \text{ kg/m}^3$, $c = 900 \text{ J/kg}\cdot\text{K}$, $k = 15 \text{ W/m}\cdot\text{K}$.

ANALYSIS: Not knowing the convection coefficient, the Biot number cannot be calculated to determine whether the rods behave as spacewise isothermal objects. Using the relations from Section 5.6, Radial Systems with Convection, for the infinite cylinder, Eq. 5.50, evaluate

$Fo = \alpha t / r_o^2$, and knowing $T(r_o, t_o)$, a trial-and-error solution is required to find $Bi = h r_o / k$ and hence, h . Using the *IHT Transient Conduction* model for the *Cylinder*, the following results are readily calculated for the 40-mm rod. With $t_o = 280 \text{ s}$,

$$Fo = 4.667 \quad Bi = 0.264 \quad h = 197.7 \text{ W/m}^2 \cdot \text{K}$$

For the 80-mm rod, with the foregoing value for h , with $T(r_o, t_o) = 60^\circ\text{C}$, find

$$Bi = 0.528 \quad Fo = 2.413 \quad t_o = 579 \text{ s} \quad <$$

COMMENTS: (1) The time-to-cool, t_o , for the 80-mm rod is slightly more than twice that for the 40-mm rod. Did you anticipate this result? Did you believe the times would be proportional to the diameter squared?

(2) The simplest approach to explaining the relationship between t_o and the diameter follows from the lumped capacitance analysis, Eq. 5.13, where for the same θ/θ_i , we expect $Bi \cdot Fo_o$ to be a constant. That is,

$$\frac{h \cdot r_o}{k} \times \frac{\alpha t_o}{r_o^2} = C$$

yielding $t_o \sim r_o^2$ (not r_o).

PROBLEM 5.55

KNOWN: Initial temperature, density, specific heat and diameter of cylindrical rod. Convection coefficient and temperature of air flow. Time for centerline to reach a prescribed temperature. Dependence of convection coefficient on flow velocity.

FIND: (a) Thermal conductivity of material, (b) Effect of velocity and centerline temperature and temperature histories for selected velocities.

SCHEMATIC:

ASSUMPTIONS: (1) Lumped capacitance analysis can not be used but one-term approximation for an infinite cylinder is appropriate, (2) One-dimensional conduction in r , (3) Constant properties, (4) Negligible radiation, (5) Negligible effect of thermocouple hole on conduction.

ANALYSIS: (a) With $\theta_o^* = [T_o(0, 1136 \text{ s}) - T_\infty] / (T_i - T_\infty) = (40 - 25) / (100 - 25) = 0.20$, Eq. 5.49c yields

$$Fo = \frac{\alpha t}{r_o^2} = \frac{k t}{\rho c_p r_o^2} = \frac{k(1136 \text{ s})}{1200 \text{ kg/m}^3 \times 1250 \text{ J/kg} \cdot \text{K} \times (0.02 \text{ m})^2} = -\ln(0.2/C_1) / \zeta_1^2 \quad (1)$$

Because C_1 and ζ_1 depend on $Bi = hr_o/k$, a trial-and-error procedure must be used. For example, a value of k may be assumed and used to calculate Bi , which may then be used to obtain C_1 and ζ_1 from Table 5.1. Substituting C_1 and ζ_1 into Eq. (1), k may be computed and compared with the assumed value. Iteration continues until satisfactory convergence is obtained, with

$$k \approx 0.30 \text{ W/m} \cdot \text{K}$$

<

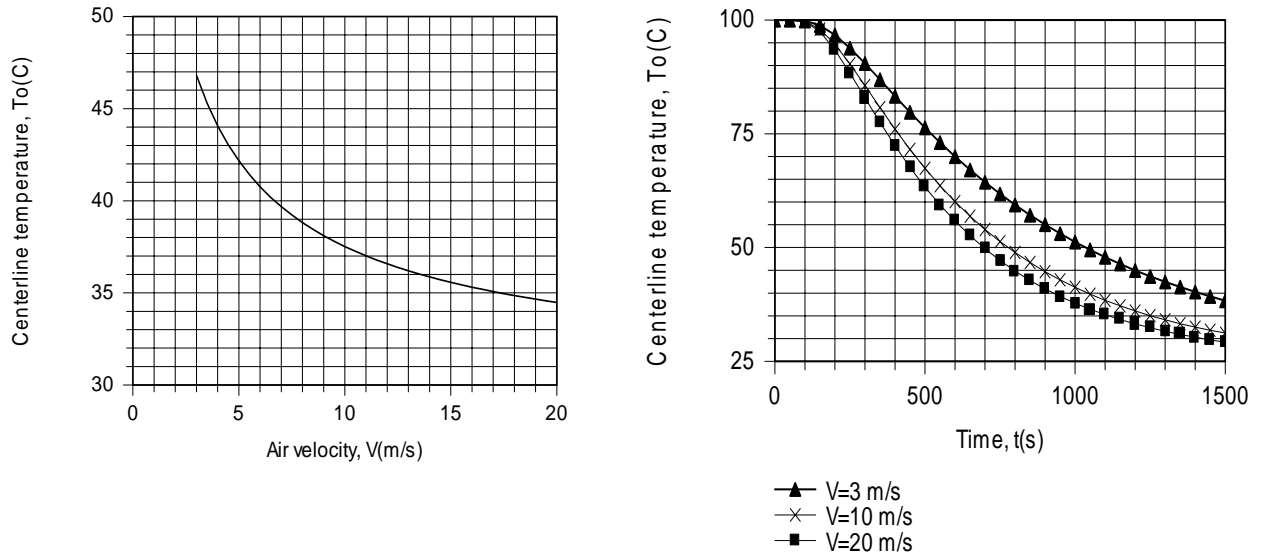

and, hence, $Bi = 3.67$, $C_1 = 1.45$, $\zeta_1 = 1.87$ and $Fo = 0.568$. For the above value of k ,

$-\ln(0.2/C_1) / \zeta_1^2 = 0.567$, which equals the Fourier number, as prescribed by Eq. (1).

(b) With $h = 55 \text{ W/m}^2 \cdot \text{K}$ for $V = 6.8 \text{ m/s}$, $h = CV^{0.618}$ yields a value of $C = 16.8 \text{ W} \cdot \text{s}^{0.618} / \text{m}^{2.618} \cdot \text{K}$. The desired variations of the centerline temperature with velocity (for $t = 1136 \text{ s}$) and time (for $V = 3, 10$ and 20 m/s) are as follows:

Continued

PROBLEM 5.55 (Cont.)

With increasing V from 3 to 20 m/s, h increases from 33 to 107 $\text{W/m}^2\cdot\text{K}$, and the enhanced cooling reduces the centerline temperature at the prescribed time. The accelerated cooling associated with increasing V is also revealed by the temperature histories, and the time required to achieve thermal equilibrium between the air and the cylinder decreases with increasing V .

COMMENTS: (1) For the smallest value of $h = 33 \text{ W/m}^2\cdot\text{K}$, $\text{Bi} \equiv h (r_o/2)/k = 1.1 \gg 0.1$, and use of the lumped capacitance method is clearly inappropriate.

(2) The *IHT* Transient Conduction Model for a cylinder was used to perform the calculations of Part (b). Because the model is based on the exact solution, Eq. 5.47a, it is accurate for values of $\text{Fo} < 0.2$, as well as $\text{Fo} > 0.2$. Although in principle, the model may be used to calculate the thermal conductivity for the conditions of Part (a), convergence is elusive and may only be achieved if the initial guesses are close to the correct results.

PROBLEM 5.56

KNOWN: Diameter, initial temperature and properties of stainless steel rod. Temperature and convection coefficient of coolant.

FIND: Temperature distributions for prescribed convection coefficients and times.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties.

ANALYSIS: The *IHT* model is based on the exact solution to the heat equation, Eq. 5.47. The results are plotted as follows

For $h = 100 \text{ W/m}^2\text{-K}$, $Bi = hr_o/k = 0.1$, and as expected, the temperature distribution is nearly uniform throughout the rod. For $h = 1000 \text{ W/m}^2\text{-K}$ ($Bi = 1$), temperature variations within the rod are not negligible. In this case the centerline-to-surface temperature difference is comparable to the surface-to-fluid temperature difference. For $h = 5000 \text{ W/m}^2\text{-K}$ ($Bi = 5$), temperature variations within the rod are large and $[T(0,t) - T(r_o,t)]$ is substantially larger than $[T(r_o,t) - T_\infty]$.

COMMENTS: With increasing Bi , conduction within the rod, and not convection from the surface, becomes the limiting process for heat loss.

PROBLEM 5.57

KNOWN: A ball bearing is suddenly immersed in a molten salt bath; heat treatment to harden occurs at locations with $T > 1000$ K.

FIND: Time required to harden outer layer of 1 mm.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) $Bi \geq 0.2$.

ANALYSIS: Since any location within the ball whose temperature exceeds 1000 K will be hardened, the problem is to find the time when the location $r = 9$ mm reaches 1000 K. Then a 1 mm outer layer will be hardened. Begin by finding the Biot number.

$$Bi = \frac{h r_o}{k} = \frac{5000 \text{ W/m}^2 \cdot \text{K} (0.020 \text{ m}/2)}{50 \text{ W/m}\cdot\text{K}} = 1.00.$$

Using the one-term approximate solution for a sphere, find

$$Fo = -\frac{1}{\zeta_1^2} \ln \left[\theta^* / C_1 \frac{1}{\zeta_1 r^*} \sin(\zeta_1 r^*) \right].$$

From Table 5.1 with $Bi = 1.00$, for the sphere find $\zeta_1 = 1.5708$ rad and $C_1 = 1.2732$. With $r^* = r/r_o = (9 \text{ mm}/10 \text{ mm}) = 0.9$, substitute numerical values.

$$Fo = \frac{-1}{(1.5708)^2} \ln \left[\frac{(1000 - 1300) \text{ K}}{(300 - 1300) \text{ K}} / 1.2732 \frac{1}{1.5708 \times 0.9} \sin(1.5708 \times 0.9 \text{ rad}) \right] = 0.441.$$

From the definition of the Fourier number with $\alpha = k/\rho c$,

$$t = Fo \frac{r_o^2}{\alpha} = Fo \cdot r_o^2 \frac{\rho c}{k} = 0.441 \times \left[\frac{0.020 \text{ m}}{2} \right]^2 7800 \frac{\text{kg}}{\text{m}^3} \times 500 \frac{\text{J}}{\text{kg}\cdot\text{K}} / 50 \text{ W/m}\cdot\text{K} = 3.4 \text{ s.} \quad <$$

COMMENTS: (1) Note the very short time required to harden the ball. At this time it can be easily shown the center temperature is $T(0, 3.4 \text{ s}) = 871$ K.

PROBLEM 5.58

KNOWN: Steel ball bearings at an initial, uniform temperature are to be cooled by convection while passing through a refrigerated chamber; bearings are to be cooled to a temperature such that 70% of the thermal energy is removed.

FIND: Residence time of the balls in the 5 m-long chamber and recommended drive velocity for the conveyor.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible conduction between ball and conveyor surface, (2) Negligible radiation exchange with surroundings, (3) Constant properties, (4) Uniform convection coefficient over ball's surface.

ANALYSIS: The Biot number for the lumped capacitance analysis is

$$Bi \equiv \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} (0.1\text{m}/3)}{50 \text{ W/m} \cdot \text{K}} = 0.67.$$

Since $Bi > 0.1$, lumped capacitance analysis is not appropriate. We assume that the one-term approximation to the exact solution is valid and check later. The Biot number for the exact solution is

$$Bi = \frac{hr_o}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} \times 0.1\text{m}}{50 \text{ W/m} \cdot \text{K}} = 2.0,$$

From Table 5.1, $\zeta_1 = 2.0288$, $C_1 = 1.4793$. From Equation 5.52c, with $Q/Q_o = 0.70$, we can solve for θ_o^* :

$$\theta_o^* = \left(1 - \frac{Q}{Q_o}\right) \frac{\zeta_1^3}{3[\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)]} = (1 - 0.7) \frac{2.0288^3}{3[\sin(2.0288) - 2.0288 \cos(2.0288)]} = 0.465$$

From Eq. 5.50c, we can solve for Fo :

$$Fo = -\frac{1}{\zeta_1^2} \ln(\theta_o^*/C_1) = -\frac{1}{2.0288^2} \ln(0.465/1.4793) = 0.281$$

Note that the one-term approximation is indeed valid, since $Fo > 0.2$. Then

$$t = Fo \frac{r_o^2}{\alpha} = 0.281 \frac{(0.1 \text{ m})^2}{2 \times 10^{-5} \text{ m}^2/\text{s}} = 140 \text{ s}$$

The velocity of the conveyor is expressed in terms of the length L and residence time t . Hence

$$V = \frac{L}{t} = \frac{5 \text{ m}}{140 \text{ s}} = 0.036 \text{ m/s} = 36 \text{ mm/s.} \quad <$$

COMMENTS: Referring to Equation 5.10, note that for a sphere, the characteristic length is

$$L_c = V/A_s = \frac{4}{3} \pi r_o^3 / 4\pi r_o^2 = \frac{r_o}{3}.$$

However, when using the exact solution or one-term approximation, note that $Bi \equiv h r_o/k$.

PROBLEM 5.59

KNOWN: Diameter and initial temperature of ball bearings to be quenched in an oil bath.

FIND: (a) Time required for surface to cool to 100°C and the corresponding center temperature, (b) Oil bath cooling requirements.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction in ball bearings, (2) Constant properties.

PROPERTIES: Table A-1, St. St., AISI 304, ($T \approx 500^\circ\text{C}$): $k = 22.2 \text{ W/m}\cdot\text{K}$, $c_p = 579 \text{ J/kg}\cdot\text{K}$, $\rho = 7900 \text{ kg/m}^3$, $\alpha = 4.85 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: (a) To determine whether use of the lumped capacitance method is suitable, first compute

$$\text{Bi} = \frac{h(r_o/3)}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} (0.010 \text{ m}/3)}{22.2 \text{ W/m}\cdot\text{K}} = 0.15.$$

We conclude that, although the lumped capacitance method could be used as a first approximation, the exact solution should be used in the interest of improving accuracy. We assume that the one-term approximation is valid and check later. Hence, with

$$\text{Bi} = \frac{hr_o}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} (0.01 \text{ m})}{22.2 \text{ W/m}\cdot\text{K}} = 0.450$$

from Table 5.1, $\zeta_1 = 1.1092$, $C_1 = 1.1301$. Then

$$\theta^*(r^* = 1, \text{Fo}) = \frac{T(r_o, t) - T_\infty}{T_i - T_\infty} = \frac{100^\circ\text{C} - 40^\circ\text{C}}{850^\circ\text{C} - 40^\circ\text{C}} = 0.0741$$

and Equation 5.50b can be solved for θ_o^* :

$$\theta_o^* = \theta^* \zeta_1 r^* / \sin(\zeta_1 r^*) = 0.0741 \times 1.1092 \times 1 / \sin(1.1092) = 0.0918$$

Then Equation 5.50c can be solved for Fo:

$$\text{Fo} = -\frac{1}{\zeta_1^2} \ln(\theta_o^* / C_1) = -\frac{1}{1.1092^2} \ln(0.0918 / 1.1301) = 2.04$$

$$t = \frac{r_o^2 \text{Fo}}{\alpha} = \frac{(0.01 \text{ m})^2 (2.04)}{4.85 \times 10^{-6} \text{ m}^2/\text{s}} = 42 \text{ s.}$$

Note that the one-term approximation is accurate, since $\text{Fo} > 0.2$.

Continued

PROBLEM 5.59 (Cont.)

Also,

$$\theta_o = T_o - T_\infty = 0.0918(T_i - T_\infty) = 0.0918(850 - 40) = 74^\circ\text{C}$$

$$T_o = 114^\circ\text{C}$$

<

(b) Equation 5.52 can be used to calculate the heat loss from a single ball:

$$\frac{Q}{Q_o} = 1 - \frac{3\theta_o^*}{\zeta_1^3} [\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)] = 1 - \frac{3 \times 0.0918}{1.1092^3} [\sin(1.1092) - 1.1092 \cos(1.1092)] = 0.919$$

Hence, from Equation 5.44,

$$Q = 0.919 \rho c_p V (T_i - T_\infty)$$

$$Q = 0.919 \times 7900 \text{ kg/m}^3 \times 579 \text{ J/kg} \cdot \text{K} \times \frac{\pi}{6} (0.02 \text{ m})^3 \times 810^\circ\text{C}$$

$$Q = 1.43 \times 10^4 \text{ J}$$

is the amount of energy transferred from a single ball during the cooling process. Hence, the oil bath cooling rate must be

$$\dot{q} = 10^4 Q / 3600 \text{ s}$$

$$\dot{q} = 4 \times 10^4 \text{ W} = 40 \text{ kW.}$$

<

COMMENTS: If the lumped capacitance method is used, the cooling time, obtained from Equation 5.5, would be $t = 39.7 \text{ s}$, where the ball is assumed to be uniformly cooled to 100°C . This result, and the fact that $T_o - T(r_o) = 15^\circ\text{C}$ at the conclusion, suggests that use of the lumped capacitance method would have been reasonable.

PROBLEM 5.60

KNOWN: Sphere quenching in a constant temperature bath.

FIND: (a) Plot $T(0,t)$ and $T(r_o,t)$ as function of time, (b) Time required for surface to reach 415 K, t' , (c) Heat flux when $T(r_o, t') = 415$ K, (d) Energy lost by sphere in cooling to $T(r_o, t') = 415$ K, (e) Steady-state temperature reached after sphere is insulated at $t = t'$, (f) Effect of h on center and surface temperature histories.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) Uniform initial temperature.

ANALYSIS: (a) Calculate Biot number to determine if sphere behaves as spatially isothermal object,

$$Bi = \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{75\text{ W/m}^2\cdot\text{K}(0.015\text{ m/3})}{1.7\text{ W/m}\cdot\text{K}} = 0.22.$$

Hence, temperature gradients exist in the sphere and $T(r,t)$ vs. t appears as shown above.

(b) The exact solution may be used to find t' when $T(r_o, t') = 415$ K. We assume that the one-term approximation is valid and check later. Hence, with

$$Bi = \frac{hr_o}{k} = \frac{75\text{ W/m}^2\cdot\text{K}(0.015\text{ m})}{1.7\text{ W/m}\cdot\text{K}} = 0.662$$

from Table 5.1, $\zeta_1 = 1.3188$, $C_1 = 1.1877$. Then

$$\theta^*(r^* = 1, Fo) = \frac{T(r_o, t) - T_\infty}{T_i - T_\infty} = \frac{415^\circ\text{C} - 320^\circ\text{C}}{800^\circ\text{C} - 320^\circ\text{C}} = 0.1979$$

and Equation 5.50b can be solved for θ_o^* :

$$\theta_o^* = \theta^* \zeta_1 r^* / \sin(\zeta_1 r^*) = 0.1979 \times 1.3188 \times 1 / \sin(1.3188) = 0.2695$$

Then Equation 5.50c can be solved for Fo :

$$Fo = -\frac{1}{\zeta_1^2} \ln(\theta_o^* / C_1) = -\frac{1}{1.3188^2} \ln(0.2695 / 1.1877) = 0.853$$

$$t' = Fo \frac{r_o^2}{\alpha} = Fo \cdot \frac{\rho c_p}{k} \cdot r_o^2 = 0.853 \frac{400\text{ kg/m}^3 \times 1600\text{ J/kg}\cdot\text{K}}{1.7\text{ W/m}\cdot\text{K}} \times (0.015\text{ m})^2 = 72\text{ s} \quad <$$

Note that the one-term approximation is accurate, since $Fo > 0.2$.

Continued...

PROBLEM 5.60 (Cont.)

(c) The heat flux at the outer surface at time t' is given by Newton's law of cooling

$$q'' = h[T(r_o, t') - T_\infty] = 75 \text{ W/m}^2 \cdot \text{K} [415 - 320] \text{ K} = 7125 \text{ W/m}^2. \quad <$$

The manner in which q'' is calculated indicates that energy is leaving the sphere.

(d) The energy lost by the sphere during the cooling process from $t = 0$ to t' can be determined from Equation 5.52:

$$\frac{Q}{Q_o} = 1 - \frac{3\theta_o^*}{\zeta_1^3} [\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)] = 1 - \frac{3 \times 0.2695}{1.3188^3} [\sin(1.3188) - 1.3188 \cos(1.3188)] = 0.775$$

The energy loss by the sphere with $V = (\pi D^3)/6$ is therefore, from Equation 5.44,

$$Q = 0.775 Q_o = 0.775 \rho \left(\pi D^3 / 6 \right) c_p (T_i - T_\infty)$$

$$Q = 0.775 \times 400 \text{ kg/m}^3 \left(\pi [0.030 \text{ m}]^3 / 6 \right) 1600 \text{ J/kg} \cdot \text{K} (800 - 320) \text{ K} = 3364 \text{ J} \quad <$$

(e) If at time t' the surface of the sphere is perfectly insulated, eventually the temperature of the sphere will be uniform at $T(\infty)$. Applying conservation of energy to the sphere over a *time interval*, $E_{\text{in}} - E_{\text{out}} = \Delta E \equiv E_{\text{final}} - E_{\text{initial}}$. Hence, $-Q = \rho c V [T(\infty) - T_\infty] - Q_o$, where $Q_o \equiv \rho c V [T_i - T_\infty]$. Dividing by Q_o and regrouping, we obtain

$$T(\infty) = T_\infty + (1 - Q/Q_o)(T_i - T_\infty) = 320 \text{ K} + (1 - 0.775)(800 - 320) \text{ K} = 428 \text{ K} \quad <$$

(f) Using the IHT *Transient Conduction Model* for a *Sphere*, the following graphical results were generated.

The quenching process is clearly accelerated by increasing h from 75 to $200 \text{ W/m}^2 \cdot \text{K}$ and is virtually completed by $t \approx 100 \text{ s}$ for the larger value of h . Note that, for both values of h , the temperature difference $[T(0, t) - T(r_o, t)]$ decreases with increasing t . Although the surface heat flux for $h = 200 \text{ W/m}^2 \cdot \text{K}$ is initially larger than that for $h = 75 \text{ W/m}^2 \cdot \text{K}$, the more rapid decline in $T(r_o, t)$ causes it to become smaller at $t \approx 30 \text{ s}$.

COMMENTS: Using the *Transient Conduction/Sphere* model in *IHT* based upon multiple-term series solution, the following results were obtained: $t' = 72.1 \text{ s}$; $Q/Q_o = 0.7745$, and $T(\infty) = 428 \text{ K}$.

PROBLEM 5.61

KNOWN: Two spheres, A and B, initially at uniform temperatures of 800 K and simultaneously quenched in large, constant temperature baths each maintained at 320 K; properties of the spheres and convection coefficients.

FIND: (a) Show in a qualitative manner, on T-t coordinates, temperatures at the center and the outer surface for each sphere; explain features of the curves; (b) Time required for the outer surface of each sphere to reach 415 K, (c) Energy gained by each bath during process of cooling spheres to a surface temperature of 415 K.

SCHEMATIC:

	<u>Sphere A</u>	<u>Sphere B</u>
r_o (mm)	150	15
ρ (kg/m ³)	1600	400
c (J/kg·K)	400	1600
k (W/m·K)	170	1.7
h (W/m ² ·K)	5	50

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Uniform properties, (3) Constant convection coefficient.

ANALYSIS: (a) From knowledge of the Biot number and the thermal time constant, it is possible to qualitatively represent the temperature distributions. From Equation 5.10, with $L_c = r_o/3$, find

$$Bi_A = \frac{5 \text{ W/m}^2 \cdot \text{K} (0.150 \text{ m}/3)}{170 \text{ W/m} \cdot \text{K}} = 1.47 \times 10^{-3}$$

$$Bi = \frac{h(r_o/3)}{k}$$

$$Bi_B = \frac{50 \text{ W/m}^2 \cdot \text{K} (0.015 \text{ m}/3)}{1.7 \text{ W/m} \cdot \text{K}} = 0.147$$

The thermal time constant for a lumped capacitance system from Equation 5.7 is

$$\tau = \left[\frac{1}{hA_s} \right] (\rho V c) \quad \tau_A = \frac{1600 \text{ kg/m}^3 \times (0.150 \text{ m})^3 \times 400 \text{ J/kg} \cdot \text{K}}{3 \times 5 \text{ W/m}^2 \cdot \text{K}} = 6400 \text{ s}$$

$$\tau = \frac{\rho r_o c}{3h} \quad \tau_B = \frac{400 \text{ kg/m}^3 \times (0.015 \text{ m})^3 \times 1600 \text{ J/kg} \cdot \text{K}}{3 \times 50 \text{ W/m}^2 \cdot \text{K}} = 64 \text{ s}$$

When $Bi \ll 0.1$, the sphere will cool in a spacewise isothermal manner (Sphere A). For sphere B, $Bi > 0.1$, hence gradients will be important. Note that the thermal time constant of A is much larger than for B; hence, A will cool much slower. See sketch for these features.

(b) Recognizing that $Bi_A < 0.1$, Sphere A can be treated as spacewise isothermal and analyzed using the lumped capacitance method. From Equation 5.6 and 5.7, with $T = 415 \text{ K}$

$$\frac{\theta}{\theta_i} = \frac{T - T_\infty}{T_i - T_\infty} = \exp(-t/\tau)$$

Continued

PROBLEM 5.61 (Cont.)

$$t_A = -\tau_A \left[\ln \frac{T - T_\infty}{T_i - T_\infty} \right] = -6400 \text{ s} \left[\ln \frac{415 - 320}{800 - 320} \right] = 10,367 \text{ s} = 2.88 \text{ h.} \quad <$$

Note that since the sphere is nearly isothermal, the surface and inner temperatures are approximately the same.

Since $Bi_B > 0.1$, *Sphere B* must be treated by the exact method of solution. We assume that the one-term approximation is valid and check later. Hence, with

$$Bi_B = \frac{hr_o}{k} = \frac{50 \text{ W/m}^2 \cdot \text{K} (0.015 \text{ m})}{1.7 \text{ W/m} \cdot \text{K}} = 0.441$$

from Table 5.1, $\zeta_1 = 1.0992$, $C_1 = 1.1278$. Then

$$\theta^*(r^* = 1, Fo) = \frac{T(r_o, t) - T_\infty}{T_i - T_\infty} = \frac{415^\circ\text{C} - 320^\circ\text{C}}{800^\circ\text{C} - 320^\circ\text{C}} = 0.1979$$

and Equation 5.50b can be solved for θ_o^* :

$$\theta_o^* = \theta^* \zeta_1 r^* / \sin(\zeta_1 r^*) = 0.1979 \times 1.0992 \times 1 / \sin(1.0992) = 0.2442$$

Then Equation 5.50c can be solved for Fo :

$$Fo = -\frac{1}{\zeta_1^2} \ln(\theta_o^* / C_1) = -\frac{1}{1.0992^2} \ln(0.2442 / 1.1278) = 1.266$$

$$t_B = Fo \frac{r_o^2}{\alpha} = Fo \cdot \frac{\rho c_p}{k} \cdot r_o^2 = 1.266 \frac{400 \text{ kg/m}^3 \times 1600 \text{ J/kg} \cdot \text{K}}{1.7 \text{ W/m} \cdot \text{K}} \times (0.015 \text{ m})^2 = 107 \text{ s} <$$

Note that the one-term approximation is accurate, since $Fo > 0.2$.

(c) To determine the energy change by the spheres during the cooling process, apply the conservation of energy requirement on a time interval basis.

Sphere A:

$$E_{in} - E_{out} = \Delta E \quad -Q_A = \Delta E = E(t) - E(0).$$

$$Q_A = \rho c V [T(t) - T_i] = 1600 \text{ kg/m}^3 \times 400 \text{ J/kg} \cdot \text{K} \times (4/3)\pi (0.150 \text{ m})^3 [415 - 800] \text{ K}$$

$$Q_A = 3.483 \times 10^6 \text{ J.} \quad <$$

Note that this simple expression is a consequence of the spacewise isothermal behavior.

$$\text{Sphere B:} \quad E_{in} - E_{out} = \Delta E \quad -Q_B = E(t) - E(0).$$

For the nonisothermal sphere, Equation 5.52 can be used to evaluate Q_B .

$$\frac{Q_B}{Q_o} = 1 - \frac{3\theta_o^*}{\zeta_1^3} [\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)] = 1 - \frac{3 \times 0.2442}{1.0992^3} [\sin(1.0992) - 1.0992 \cos(1.0992)] = 0.784$$

The energy transfer from the sphere during the cooling process, using Equation 5.44, is

$$Q_B = 0.784 Q_o = 0.784 [\rho c V (T_i - T_\infty)]$$

$$Q_B = 0.784 \times 400 \text{ kg/m}^3 \times 1600 \text{ J/kg} \cdot \text{K} (4/3)\pi (0.015 \text{ m})^3 (800 - 320) \text{ K} = 3405 \text{ J} \quad <$$

COMMENTS: In summary:	Sphere	$Bi = hr_o/k$	$\tau(s)$	$t(s)$	$Q(J)$
	A	4.41×10^{-3}	6400	10,370	3.48×10^6
	B	0.44	64	107	3405

PROBLEM 5.62

KNOWN: Spheres of 40-mm diameter heated to a uniform temperature of 400°C are suddenly removed from an oven and placed in a forced-air bath operating at 25°C with a convection coefficient of 300 W/m²·K.

FIND: (a) Time the spheres must remain in the bath for 80% of the thermal energy to be removed, and (b) Uniform temperature the spheres will reach when removed from the bath at this condition and placed in a carton that prevents further heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction in the spheres, (2) Constant properties, and (3) No heat loss from sphere after removed from the bath and placed into the packing carton.

PROPERTIES: Sphere (*given*): $\rho = 3000 \text{ kg/m}^3$, $c = 850 \text{ J/kg}\cdot\text{K}$, $k = 15 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) From Eq. 5.52, the fraction of thermal energy removed during the time interval $\Delta t = t_0$ is

$$\frac{Q}{Q_0} = 1 - 3\theta_0^* / \zeta_1^3 [\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)] \quad (1)$$

where $Q/Q_0 = 0.8$. The Biot number is

$$Bi = hr_0 / k = 300 \text{ W/m}^2 \cdot \text{K} \times 0.020 \text{ m} / 15 \text{ W/m} \cdot \text{K} = 0.40$$

and for the one-term series approximation, from Table 5.1,

$$\zeta_1 = 1.0528 \text{ rad} \quad C_1 = 1.1164 \quad (2)$$

The dimensionless temperature θ_0^* , Eq. 5.31, follows from Eq. 5.50.

$$\theta_0^* = C_1 \exp(-\zeta_1^2 Fo) \quad (3)$$

where $Fo = \alpha t_0 / r_0^2$. Substituting Eq. (3) into Eq. (1), solve for Fo and t_0 .

$$\frac{Q}{Q_0} = 1 - 3 C_1 \exp(-\zeta_1^2 Fo) / \zeta_1^3 [\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)] \quad (4)$$

$$Fo = 1.45 \quad t_0 = 98.6 \text{ s} \quad <$$

(b) Performing an overall energy balance on the sphere during the interval of time $t_0 \leq t \leq \infty$,

$$E_{in} - E_{out} = \Delta E = E_f - E_i = 0 \quad (5)$$

where E_i represents the thermal energy in the sphere at t_0 ,

$$E_i = (1 - 0.8) Q_0 = (1 - 0.8) \rho c V (T_i - T_\infty) \quad (6)$$

and E_f represents the thermal energy in the sphere at $t = \infty$,

$$E_f = \rho c V (T_{avg} - T_\infty) \quad (7)$$

Combining the relations, find the average temperature

$$\rho c V [(T_{avg} - T_\infty) - (1 - 0.8)(T_i - T_\infty)] = 0$$

$$T_{avg} = 100^\circ\text{C} \quad <$$

PROBLEM 5.63

KNOWN: Diameter, density, specific heat and thermal conductivity of Pyrex spheres in packed bed thermal energy storage system. Convection coefficient and inlet gas temperature.

FIND: Time required for sphere to acquire 90% of maximum possible thermal energy and the corresponding center temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction in sphere, (2) Negligible heat transfer to or from a sphere by radiation or conduction due to contact with adjoining spheres, (3) Constant properties.

ANALYSIS: With $Bi \equiv h(r_o/3)/k = 75 \text{ W/m}^2 \cdot \text{K} (0.0125\text{m})/1.4 \text{ W/m} \cdot \text{K} = 0.67$, the approximate solution for one-dimensional transient conduction in a sphere is used to obtain the desired results. We first use Eq. (5.52) to obtain θ_o^* .

$$\theta_o^* = \frac{\zeta_1^3}{3[\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)]} \left(1 - \frac{Q}{Q_o} \right)$$

With $Bi \equiv hr_o/k = 2.01$, $\zeta_1 \approx 2.03$ and $C_1 \approx 1.48$ from Table 5.1. Hence,

$$\theta_o^* = \frac{0.1(2.03)^3}{3[0.896 - 2.03(-0.443)]} = \frac{0.837}{5.386} = 0.155$$

The center temperature is therefore

$$T_o = T_{g,i} + 0.155(T_i - T_{g,i}) = 300^\circ\text{C} - 42.7^\circ\text{C} = 257.3^\circ\text{C} \quad <$$

From Eq. (5.50c), the corresponding time is

$$t = -\frac{r_o^2}{\alpha \zeta_1^2} \ln \left(\frac{\theta_o^*}{C_1} \right)$$

where $\alpha = k/\rho c = 1.4 \text{ W/m} \cdot \text{K} / (2225 \text{ kg/m}^3 \times 835 \text{ J/kg} \cdot \text{K}) = 7.54 \times 10^{-7} \text{ m}^2/\text{s}$.

$$t = -\frac{(0.0375\text{m})^2 \ln(0.155/1.48)}{7.54 \times 10^{-7} \text{ m}^2/\text{s} (2.03)^2} = 1,020\text{s} \quad <$$

COMMENTS: The surface temperature at the time of interest may be obtained from Eq. (5.50b).

With $r^* = 1$,

$$T_s = T_{g,i} + (T_i - T_{g,i}) \frac{\theta_o^* \sin(\zeta_1)}{\zeta_1} = 300^\circ\text{C} - 275^\circ\text{C} \left(\frac{0.155 \times 0.896}{2.03} \right) = 280.9^\circ\text{C} \quad <$$

PROBLEM 5.64

KNOWN: Initial temperature and properties of a solid sphere. Surface temperature after immersion in a fluid of prescribed temperature and convection coefficient.

FIND: (a) Time to reach surface temperature, (b) Effect of thermal diffusivity and conductivity on thermal response.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Constant properties.

ANALYSIS: (a) For $k = 15 \text{ W/m}\cdot\text{K}$, the Biot number is

$$\text{Bi} = \frac{h(r_o/3)}{k} = \frac{300 \text{ W/m}^2\cdot\text{K} (0.05 \text{ m}/3)}{15 \text{ W/m}\cdot\text{K}} = 0.333.$$

Hence, the lumped capacitance method cannot be used. From Equation 5.50a,

$$\frac{T - T_\infty}{T_i - T_\infty} = C_1 \exp(-\zeta_1^2 \text{Fo}) \frac{\sin(\zeta_1 r^*)}{\zeta_1 r^*}.$$

At the surface, $r^* = 1$. From Table 5.1, for $\text{Bi} = 1.0$, $\zeta_1 = 1.5708 \text{ rad}$ and $C_1 = 1.2732$. Hence,

$$\frac{60 - 75}{25 - 75} = 0.30 = 1.2732 \exp(-1.5708^2 \text{Fo}) \frac{\sin 90^\circ}{1.5708}$$

$$\exp(-2.467 \text{Fo}) = 0.370$$

$$\text{Fo} = \frac{\alpha t}{r_o^2} = 0.403$$

$$t = 0.403 \frac{r_o^2}{\alpha} = 0.403 \frac{(0.05 \text{ m})^2}{10^{-5} \text{ m}^2/\text{s}} = 100 \text{ s}$$

<

(b) Using the IHT *Transient Conduction Model* for a *Sphere* to perform the parametric calculations, the effect of α is plotted for $k = 15 \text{ W/m}\cdot\text{K}$.

Continued...

PROBLEM 5.64 (Cont.)

For fixed k and increasing α , there is a reduction in the thermal capacity (ρc_p) of the material, and hence the amount of thermal energy which must be added to increase the temperature. With increasing α , the material therefore responds more quickly to a change in the thermal environment, with the response at the center lagging that of the surface.

The effect of k is plotted for $\alpha = 10^{-5} \text{ m}^2/\text{s}$.

With increasing k for fixed α , there is a corresponding increase in ρc_p , and the material therefore responds more slowly to a thermal change in its surroundings. The thermal response of the center lags that of the surface, with temperature differences, $T(r_o, t) - T(0, t)$, during early stages of solidification increasing with decreasing k .

COMMENTS: Use of this technique to determine h from measurement of $T(r_o)$ at a prescribed t requires an iterative solution of the governing equations.

PROBLEM 5.65

KNOWN: Temperature requirements for cooling the spherical material of Ex. 5.4 in air and in a water bath.

FIND: (a) For step 1, the time required for the center temperature to reach $T(0,t) = 335^\circ\text{C}$ while cooling in air at 20°C with $h = 10 \text{ W/m}^2\cdot\text{K}$; find the Biot number; do you expect radial gradients to be appreciable?; compare results with hand calculations in Ex. 5.4; (b) For step 2, time required for the center temperature to reach $T(0,t) = 50^\circ\text{C}$ while cooling in water bath at 20°C with $h = 6000 \text{ W/m}^2\cdot\text{K}$; and (c) For step 2, calculate and plot the temperature history, $T(x,t)$ vs. t , for the center and surface of the sphere; explain features; when do you expect the temperature gradients in the sphere to be the largest? Use the IHT Models / Transient Conduction / Sphere model as your solution tool.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the radial direction, (2) Constant properties.

ANALYSIS: The IHT model represents the series solution for the sphere providing the temperatures evaluated at (r,t) . A selected portion of the IHT code used to obtain results is shown in the Comments.

(a) Using the IHT model with step 1 conditions, the time required for $T(0,t_a) = T_{xt} = 335^\circ\text{C}$ with $r = 0$ and the Biot number are:

$$t_a = 94.2 \text{ s} \qquad \text{Bi} = 0.0025 \qquad <$$

Radial temperature gradients will not be appreciable since $\text{Bi} = 0.0025 \ll 0.1$. The sphere behaves as space-wise isothermal object for the air-cooling process. The result is identical to the lumped-capacitance analysis result of the Text example.

(b) Using the IHT model with step 2 conditions, the time required for $T(0,t_w) = T_{xt} = 50^\circ\text{C}$ with $r = 0$ and $T_i = 335^\circ\text{C}$ is

$$t_w = 3.0 \text{ s} \qquad <$$

Radial temperature gradients will be appreciable, since $\text{Bi} = 1.5 \gg 0.1$. The sphere does not behave as a space-wise isothermal object for the water-cooling process.

(c) For the step 2 cooling process, the temperature histories for the center and surface of the sphere are calculated using the IHT model.

Continued

PROBLEM 5.65 (Cont.)

At early times, the difference between the center and surface temperature is appreciable. It is in this time region that thermal stresses will be a maximum, and if large enough, can cause fracture. Within 6 seconds, the sphere has a uniform temperature equal to that of the water bath.

COMMENTS: Selected portions of the IHT sphere model codes for steps 1 and 2 are shown below.

/ Results, for part (a), step 1, air cooling; clearly negligible gradient*

Bi	Fo	t	T _{xt}	Ti	r	ro
0.0025	25.13	94.22	335	400	0	0.005 */

// Models | Transient Conduction | Sphere - Step 1, Air cooling

// The temperature distribution $T(r,t)$ is

T_{xt} = T_{xt_trans}("Sphere",rstar,Fo,Bi,Ti,Tinf) // Eq 5.47

T_{xt} = 335 // Surface temperature

/ Results, for part (b), step 2, water cooling; Ti = 335 C*

PROBLEM 5.66

KNOWN: Two large blocks of different materials – like copper and concrete – at room temperature, 23°C.

FIND: Which block will feel cooler to the touch?

SCHEMATIC:

ASSUMPTIONS: (1) Blocks can be treated as semi-infinite solid, (2) Hand or finger temperature is 37°C.

PROPERTIES: Table A-1, Copper (300K): $\rho = 8933 \text{ kg/m}^3$, $c = 385 \text{ J/kg}\cdot\text{K}$, $k = 401 \text{ W/m}\cdot\text{K}$; Table A-3, Concrete, stone mix (300K): $\rho = 2300 \text{ kg/m}^3$, $c = 880 \text{ J/kg}\cdot\text{K}$, $k = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: Considering the block as a semi-infinite solid, the heat transfer situation corresponds to a sudden change in surface temperature, Case 1, Figure 5.7. The sensation of coolness is related to the heat flow from the hand or finger to the block. From Eq. 5.58, the surface heat flux is

$$q_s''(t) = k(T_s - T_i) / (\pi \alpha t)^{1/2} \quad (1)$$

or

$$q_s''(t) \sim (k \rho c)^{1/2} \quad \text{since} \quad \alpha = k / \rho c. \quad (2)$$

Hence for the same temperature difference, $T_s - T_i$, and elapsed time, it follows that the heat fluxes for the two materials are related as

$$\frac{q_{s,\text{copper}}''}{q_{s,\text{concrete}}''} = \frac{(k \rho c)_{\text{copper}}^{1/2}}{(k \rho c)_{\text{concrete}}^{1/2}} = \frac{\left[401 \frac{\text{W}}{\text{m}\cdot\text{K}} \times 8933 \frac{\text{kg}}{\text{m}^3} \times 385 \frac{\text{J}}{\text{kg}\cdot\text{K}} \right]^{1/2}}{\left[1.4 \frac{\text{W}}{\text{m}\cdot\text{K}} \times 2300 \frac{\text{kg}}{\text{m}^3} \times 880 \frac{\text{J}}{\text{kg}\cdot\text{K}} \right]^{1/2}} = 22.1$$

Hence, the heat flux to the copper block is more than 20 times larger than to the concrete block. The *copper* block will therefore feel noticeably cooler than the concrete one.

PROBLEM 5.67

KNOWN: Thickness and properties of plane wall. Convection coefficient.

FIND: (a) Nondimensional temperature for six different cases using four methods and (b) Explain the conditions for which the three approximate methods are good approximations of the exact solution.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties.

PROPERTIES: Steel (given): $k = 30 \text{ W/m}\cdot\text{K}$, $\rho = 7900 \text{ kg/m}^3$, $c = 640 \text{ J/kg}\cdot\text{K}$.

ANALYSIS:

(a) We perform the calculations for $h = 10 \text{ W/m}^2\cdot\text{K}$, $t = 2.5 \text{ min}$.

Exact Solution

From Equation 5.39a, evaluated at the surface $x^* = 1$,

$$\theta_s^* = \frac{T_s - T_\infty}{T_i - T_\infty} = \sum_{n=1}^{\infty} C_n \exp(-\zeta_n^2 \text{Fo}) \cos(\zeta_n)$$

For $t = 2.5 \text{ min}$,

$$\begin{aligned} \text{Fo} &= \frac{\alpha t}{L^2} = \frac{k}{\rho c} \frac{t}{L^2} \\ &= \frac{30 \text{ W/m}\cdot\text{K}}{7900 \frac{\text{kg}}{\text{m}^3} \times 640 \frac{\text{J}}{\text{kg}\cdot\text{K}}} \times \frac{(2.5 \times 60) \text{ s}}{(0.3 \text{ m})^2} = 0.0099 \end{aligned}$$

We also calculate $\text{Bi} = hL/k = 10 \text{ W/m}^2\cdot\text{K} \times 0.3 \text{ m}/30 \text{ W/m}\cdot\text{K} = 0.10$. The first four values of ζ_n are found in Table B.3, and the corresponding values of C_n can be calculated from Equation 5.39b, $C_n = 4 \sin \zeta_n / [2\zeta_n + \sin(2\zeta_n)]$. Then the first four terms in Equation 5.39a can be calculated as well. The results are tabulated below.

n	ζ_n	C_n	$C_n \exp(-\zeta_n^2 \text{Fo}) \cos(\zeta_n)$
1	0.3111	1.016	0.9664
2	3.1731	-0.0197	0.0178
3	6.2991	0.0050	0.0034
4	9.4354	-0.0022	0.0009
			$\theta_s^* = 0.989$

Continued...

PROBLEM 5.67 (Cont.)

We can see that the fourth term is small, so to a good approximation the exact solution can be found by summing the first four terms, as shown in the table. Thus

$$\theta_{s,\text{exact}}^* = 0.989 \quad \text{<}$$

First Term

From the above table,

$$\theta_{s,1\text{-term}}^* = 0.966 \quad \text{<}$$

Lumped Capacitance

From Equation 5.6,

$$\begin{aligned} \theta_{\text{lump}}^* &= \exp\left[-\frac{hA_s}{\rho Vc}t\right] = \exp\left[-\frac{ht}{\rho Lc}\right] \\ &= \exp\left[-\frac{10 \text{ W/m}^2 \cdot \text{K} \times (2.5 \times 60) \text{ s}}{7900 \text{ kg/m}^3 \times 0.3 \text{ m} \times 640 \text{ J/kg} \cdot \text{K}}\right] = 0.999 \end{aligned}$$

Semi-Infinite Solid

We use Equation 5.60 with x measured from the surface, that is $x = 0$.

$$\begin{aligned} \theta_{s,\text{semi}}^* &= \frac{T_s - T_\infty}{T_i - T_\infty} = 1 - \frac{T_s - T_i}{T_\infty - T_i} \\ &= 1 - \text{erfc}(0) + \exp\left(\frac{h^2 \alpha t}{k^2}\right) \text{erfc}\left(\frac{h\sqrt{\alpha t}}{k}\right) \\ &= 1 - 1 + \exp(\text{Bi}^2 \text{Fo}) \text{erfc}(\text{Bi} \text{Fo}^{1/2}) \\ &= \exp(0.10^2 \times 0.0099) \text{erfc}(0.10 \times (0.0099)^{1/2}) \\ &= 1.0001 \times 0.989 = 0.989 \quad \text{<} \end{aligned}$$

where the error function was evaluated from Table B.2.

Repeating the calculation for the other five cases, the following table can be compiled:

Method	$Bi = 0.1$			$Bi = 1$		
	$Fo = 0.01$	$Fo = 0.1$	$Fo = 1.0$	$Fo = 0.01$	$Fo = 0.1$	$Fo = 1.0$
Exact	0.99	0.97	0.88	0.90	0.72	0.35
First-term	0.97	0.96	0.88	0.72	0.68	0.35
Lumped	1.00	0.99	0.90	0.99	0.90	0.37
Semi-inf.	0.99	0.97	0.90	0.90	0.72	0.43

- (b) (i) The first term solution is a good approximation to the exact solution for $Fo > 0.2$. As seen in the above table, for $Fo = 1.0$, the first term solution is correct to two significant digits.

Continued...

PROBLEM 5.67 (Cont.)

(ii) The lumped capacitance solution is a good approximation to the exact solution for $Bi < 0.1$. In the above table, the lumped capacitance solution is quite accurate for $Bi = 0.1$, but not for $Bi = 1.0$.

(iii) The semi-infinite solid solution is a good approximation to the exact solution for the smaller values of Fourier, since for small t or α , or for large L , the heat doesn't penetrate through the wall and it can be treated as semi-infinite.

PROBLEM 5.68

KNOWN: Asphalt pavement, initially at 50°C, is suddenly exposed to a rainstorm reducing the surface temperature to 20°C.

FIND: Total amount of energy removed (J/m^2) from the pavement for a 30 minute period.

SCHEMATIC:

ASSUMPTIONS: (1) Asphalt pavement can be treated as a semi-infinite solid, (2) Effect of rainstorm is to suddenly reduce the surface temperature to 20°C and is maintained at that level for the period of interest.

PROPERTIES: *Table A-3, Asphalt (300K):* $\rho = 2115 \text{ kg/m}^3$, $c = 920 \text{ J/kg}\cdot\text{K}$, $k = 0.062 \text{ W/m}\cdot\text{K}$.

ANALYSIS: This solution corresponds to Case 1, Figure 5.7, and the surface heat flux is given by Eq. 5.58 as

$$q_s''(t) = k(T_s - T_i)/(\pi \alpha t)^{1/2} \quad (1)$$

The energy into the pavement over a period of time is the integral of the surface heat flux expressed as

$$Q'' = \int_0^t q_s''(t) dt. \quad (2)$$

Note that $q_s''(t)$ is into the solid and, hence, Q represents energy into the solid. Substituting Eq. (1) for $q_s''(t)$ into Eq. (2) and integrating find

$$Q'' = k(T_s - T_i) / (\pi \alpha)^{1/2} \int_0^t t^{-1/2} dt = \frac{k(T_s - T_i)}{(\pi \alpha)^{1/2}} \times 2 t^{1/2}. \quad (3)$$

Substituting numerical values into Eq. (3) with

$$\alpha = \frac{k}{\rho c} = \frac{0.062 \text{ W/m} \cdot \text{K}}{2115 \text{ kg/m}^3 \times 920 \text{ J/kg} \cdot \text{K}} = 3.18 \times 10^{-8} \text{ m}^2/\text{s}$$

find that for the 30 minute period,

$$Q'' = \frac{0.062 \text{ W/m} \cdot \text{K} (20 - 50) \text{ K}}{(\pi \times 3.18 \times 10^{-8} \text{ m}^2 / \text{s})^{1/2}} \times 2(30 \times 60 \text{ s})^{1/2} = -4.99 \times 10^5 \text{ J/m}^2. \quad <$$

COMMENTS: Note that the sign for Q'' is negative implying that energy is removed from the solid.

PROBLEM 5.69

KNOWN: Thermophysical properties and initial temperature of thick steel plate. Temperature of water jets used for convection cooling at one surface.

FIND: Time required to cool prescribed interior location to a prescribed temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in slab, (2) Validity of semi-infinite medium approximation, (3) Negligible thermal resistance between water jets and slab surface ($T_s = T_\infty$), (4) Constant properties.

ANALYSIS: The desired cooling time may be obtained from Eq. (5.57). With $T(0.025 \text{ m}, t) = 50^\circ\text{C}$,

$$\frac{T(x, t) - T_s}{T_i - T_s} = \frac{(50 - 25)^\circ\text{C}}{(300 - 25)^\circ\text{C}} = 0.0909 = \text{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

$$\frac{x}{2\sqrt{\alpha t}} = 0.0807$$

$$t = \frac{x^2}{(0.0807)^2 4\alpha} = \frac{(0.025 \text{ m})^2}{0.0261 (1.34 \times 10^{-5} \text{ m}^2/\text{s})} = 1793 \text{ s}$$

<

where $\alpha = k/\rho c = 50 \text{ W/m}\cdot\text{K} / (7800 \text{ kg/m}^3 \times 480 \text{ J/kg}\cdot\text{K}) = 1.34 \times 10^{-5} \text{ m}^2/\text{s}$.

COMMENTS: (1) Large values of the convection coefficient ($h \sim 10^4 \text{ W/m}^2\cdot\text{K}$) are associated with water jet impingement, and it is reasonable to assume that the surface is immediately quenched to the temperature of the water. (2) The surface heat flux may be determined from Eq. (5.58). In principle, the flux is infinite at $t = 0$ and decays as $t^{1/2}$.

PROBLEM 5.70

KNOWN: Temperature imposed at the surface of soil initially at 20°C. See Example 5.6.

FIND: (a) Calculate and plot the temperature history at the burial depth of 0.68 m for selected soil thermal diffusivity values, $\alpha \times 10^7 = 1.0, 1.38, \text{ and } 3.0 \text{ m}^2/\text{s}$, (b) Plot the temperature distribution over the depth $0 \leq x \leq 1.0 \text{ m}$ for times of 1, 5, 10, 30, and 60 days with $\alpha = 1.38 \times 10^{-7} \text{ m}^2/\text{s}$, (c) Plot the surface heat flux, $q_x''(0, t)$, and the heat flux at the depth of the buried main, $q_x''(0.68 \text{ m}, t)$, as a function of time for a 60 day period with $\alpha = 1.38 \times 10^{-7} \text{ m}^2/\text{s}$. Compare your results with those in the Comments section of the example. Use the *IHT Models / Transient Conduction / Semi-infinite Medium* model as the solution tool.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Soil is a semi-infinite medium, and (3) Constant properties.

ANALYSIS: The IHT model corresponds to the case 1, constant surface temperature sudden boundary condition, Eqs. 5.57 and 5.58. Selected portions of the IHT code used to obtain the graphical results below are shown in the Comments.

(a) The temperature history $T(x, t)$ for $x = 0.68 \text{ m}$ with selected soil thermal diffusivities is shown below. The results are directly comparable to the graph shown in the Ex. 5.6 comments.

Continued

PROBLEM 5.70 (Cont.)

(b) The temperature distribution $T(x,t)$ for selected times is shown below. The results are directly comparable to the graph shown in the Ex. 5.6 comments.

(c) The heat flux from the soil, $q_x''(0,t)$, and the heat flux at the depth of the buried main, $q_x''(0.68\text{m},t)$, are calculated and plotted for the time period $0 \leq t \leq 60$ days.

Both the surface and buried-main heat fluxes have a negative sign since heat is flowing in the negative x -direction. The surface heat flux is initially very large and, in the limit, approaches that of the buried-main heat flux. The latter is initially zero, and since the effect of the sudden change in surface temperature is delayed for a time period, the heat flux begins to slowly increase.

Continued

PROBLEM 5.70 (Cont.)

COMMENTS: (1) Can you explain why the surface and buried-main heat fluxes are nearly the same at $t = 60$ days? Are these results consistent with the temperature distributions? What happens to the heat flux values for times much greater than 60 days? Use your IHT model to confirm your explanation.

(2) Selected portions of the IHT code for the semi-infinite medium model are shown below.

```
// Models | Transient Conduction | Semi-infinite Solid | Constant temperature Ts
/* Model: Semi-infinite solid, initially with a uniform temperature  $T(x,0) = T_i$ , suddenly subjected to
prescribed surface boundary conditions. */
// The temperature distribution  $(T_x,t)$  is
T_xt = T_xt_semi_CST(x,alpha,t,Ts,Ti) // Eq 5.57
// The heat flux in the x direction is
q''_xt = qdprime_xt_semi_CST(x,alpha,t,Ts,Ti,k) //Eq 5.58

// Input parameters
/* The independent variables for this system and their assigned numerical values are */
Ti = 20 // initial temperature, C
k = 0.52 // thermal conductivity, W/m.K; base case condition
alpha = 1.38e-7 // thermal diffusivity,  $m^2/s$ ; base case
//alpha = 1.0e-7
//alpha = 3.0e-7

// Calculating at x-location and time t,
x = 0 // m, surface
// x = 0.68 // m, burial depth
t = t_day * 24 * 3600 // seconds to days time conversion
//t_day = 60
//t_day = 1
//t_day = 5
//t_day = 10
//t_day = 30
t_day = 20

// Surface condition: constant surface temperature
Ts = -15 // surface temperature, K
```

PROBLEM 5.71

KNOWN: Tile-iron, 254 mm to a side, at 150°C is suddenly brought into contact with tile over a subflooring material initially at $T_i = 25^\circ\text{C}$ with prescribed thermophysical properties. Tile adhesive softens in 2 minutes at 50°C, but deteriorates above 120°C.

FIND: (a) Time required to lift a tile after being heated by the tile-iron and whether adhesive temperature exceeds 120°C, (2) How much energy has been removed from the tile-iron during the time it has taken to lift the tile.

SCHEMATIC:

ASSUMPTIONS: (1) Tile and subflooring have same thermophysical properties, (2) Thickness of adhesive is negligible compared to that of tile, (3) Tile-subflooring behaves as semi-infinite solid experiencing one-dimensional transient conduction.

PROPERTIES: Tile-subflooring (given): $k = 0.15 \text{ W/m}\cdot\text{K}$, $\rho c_p = 1.5 \times 10^6 \text{ J/m}^3\cdot\text{K}$, $\alpha = k/\rho c_p = 1.00 \times 10^{-7} \text{ m}^2/\text{s}$.

ANALYSIS: (a) The tile-subflooring can be approximated as a semi-infinite solid, initially at a uniform temperature $T_i = 25^\circ\text{C}$, experiencing a sudden change in surface temperature $T_s = T(0, t) = 150^\circ\text{C}$. This corresponds to Case 1, Figure 5.7. The time required to heat the adhesive ($x_o = 4 \text{ mm}$) to 50°C follows from Eq. 5.57

$$\frac{T(x_o, t_o) - T_s}{T_i - T_s} = \text{erf} \left(\frac{x_o}{2(\alpha t_o)^{1/2}} \right)$$

$$\frac{50 - 150}{25 - 150} = \text{erf} \left(\frac{0.004 \text{ m}}{2(1.00 \times 10^{-7} \text{ m}^2/\text{s} \times t_o)^{1/2}} \right)$$

$$0.80 = \text{erf} \left(6.325 t_o^{-1/2} \right)$$

$$t_o = 48.7 \text{ s} = 0.81 \text{ min}$$

using error function values from Table B.2. Since the softening time, Δt_s , for the adhesive is 2 minutes, the time to lift the tile is

$$t_\ell = t_o + \Delta t_s = (0.81 + 2.0) \text{ min} = 2.81 \text{ min} . \quad <$$

To determine whether the adhesive temperature has exceeded 120°C , calculate its temperature at $t_\ell = 2.81 \text{ min}$; that is, find $T(x_o, t_\ell)$

$$\frac{T(x_o, t_\ell) - 150}{25 - 150} = \text{erf} \left(\frac{0.004 \text{ m}}{2(1.0 \times 10^{-7} \text{ m}^2/\text{s} \times 2.81 \times 60 \text{ s})^{1/2}} \right)$$

Continued...

PROBLEM 5.71 (Cont.)

$$T(x_o, t_\ell) - 150 = -125 \operatorname{erf}(0.4880) = -125 \times 0.5098$$

$$T(x_o, t_\ell) = 86^\circ\text{C}$$

<

Since $T(x_o, t_\ell) < 120^\circ\text{C}$, the adhesive will not deteriorate.

(b) The energy required to heat a tile to the lift-off condition is

$$Q = \int_0^{t_\ell} q_x''(0, t) \cdot A_s dt.$$

Using Eq. 5.58 for the surface heat flux $q_s''(t) = q_x''(0, t)$, find

$$Q = \int_0^{t_\ell} \frac{k(T_s - T_i)}{(\pi\alpha)^{1/2}} A_s \frac{dt}{t^{1/2}} = \frac{2k(T_s - T_i)}{(\pi\alpha)^{1/2}} A_s t_\ell^{1/2}$$

$$Q = \frac{2 \times 0.15 \text{ W/m} \cdot \text{K} (150 - 25)^\circ\text{C}}{(\pi \times 1.00 \times 10^{-7} \text{ m}^2/\text{s})^{1/2}} \times (0.254 \text{ m})^2 \times (2.81 \times 60 \text{ s})^{1/2} = 56 \text{ kJ}$$

<

COMMENTS: (1) Increasing the tile-iron temperature would decrease the time required to soften the adhesive, but the risk of burning the adhesive increases.

(2) From the energy calculation of part (b) we can estimate the size of an electrical heater, if operating continuously during the 2.81 min period, to maintain the tile-iron at a near constant temperature. The power required is

$$P = Q/t_\ell = 56 \text{ kJ} / 2.81 \times 60 \text{ s} = 330 \text{ W}.$$

Of course a much larger electrical heater would be required to initially heat the tile-iron up to the operating temperature in a reasonable period of time.

PROBLEM 5.72

KNOWN: Heat flux gage of prescribed thickness and thermophysical properties (ρ , c_p , k) initially at a uniform temperature, T_i , is exposed to a sudden change in surface temperature $T(0,t) = T_s$.

FIND: Relationships for time constant of gage when (a) backside of gage is insulated and (b) gage is imbedded in semi-infinite solid having the same thermophysical properties. Compare with equation given by manufacturer, $\tau = (4d^2 \rho c_p) / \pi^2 k$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: The time constant τ is defined as the time required for the gage to indicate, following a sudden step change, a signal which is 63.2% that of the steady-state value. The manufacturer's relationship for the time constant

$$\tau = (4d^2 \rho c_p) / \pi^2 k$$

can be written in terms of the Fourier number as

$$Fo = \frac{\alpha \tau}{d^2} = \frac{k}{\rho c_p} \cdot \frac{\tau}{d^2} = \frac{4}{\pi^2} = 0.4053.$$

The Fourier number can be determined for the two different installations.

(a) For the gage having its backside insulated, the surface and backside temperatures are T_s and $T(0,t)$, respectively. From the sketch it follows that

$$\theta_o^* = \frac{T(0, \tau) - T_s}{T_i - T_s} = 0.368.$$

From Eq. 5.41,

$$\theta_o^* = 0.368 = C_1 \exp(-\zeta_1^2 Fo)$$

Using Table 5.1 with $Bi = 100$ (as the best approximation for $Bi = hd/k \rightarrow \infty$, corresponding to sudden surface temperature change with $h \rightarrow \infty$), $\zeta_1 = 1.5552$ rad and $C_1 = 1.2731$.

Hence,

$$0.368 = 1.2731 \exp(-1.5552^2 \times Fo_a)$$

$$Fo_a = 0.513.$$

<

Continued

PROBLEM 5.72 (Cont.)

(b) For the gage imbedded in a semi-infinite medium having the same thermophysical properties, Table 5.7 (case 1) and Eq. 5.57 yield

$$\frac{T(x, \tau) - T_s}{T_i - T_s} = 0.368 = \operatorname{erf} \left[d/2(\alpha\tau)^{1/2} \right]$$

$$d/2(\alpha\tau)^{1/2} = 0.3972$$

$$\text{Fo}_b = \frac{\alpha\tau}{d^2} = \frac{1}{(2 \times 0.3972)^2} = 1.585$$

COMMENTS: Both models predict higher values of Fo than that suggested by the manufacturer. It is understandable why $\text{Fo}_b > \text{Fo}_a$ since for (b) the gage is thermally connected to an infinite medium, while for (a) it is isolated. From this analysis we conclude that the gage's transient response will depend upon the manner in which it is applied to the surface or object.

PROBLEM 5.73

KNOWN: Procedure for measuring convection heat transfer coefficient, which involves melting of a surface coating.

FIND: Melting point of coating for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in solid rod (negligible losses to insulation), (2) Rod approximated as semi-infinite medium, (3) Negligible surface radiation, (4) Constant properties, (5) Negligible thermal resistance of coating.

PROPERTIES: Copper rod (Given): $k = 400\text{ W/m}\cdot\text{K}$, $\alpha = 10^{-4}\text{ m}^2/\text{s}$.

ANALYSIS: Problem corresponds to transient conduction in a semi-infinite solid. Thermal response is given by

$$\frac{T(x,t) - T_i}{T_\infty - T_i} = \text{erfc}\left(\frac{x}{2(\alpha t)^{1/2}}\right) - \left[\exp\left(\frac{hx}{k} + \frac{h^2 \alpha t}{k^2}\right)\right] \left[\text{erfc}\left(\frac{x}{2(\alpha t)^{1/2}} + \frac{h(\alpha t)^{1/2}}{k}\right)\right].$$

For $x = 0$, $\text{erfc}(0) = 1$ and $T(x,t) = T(0,t) = T_s$. Hence

$$\frac{T_s - T_i}{T_\infty - T_i} = 1 - \exp\left(\frac{h^2 \alpha t}{k^2}\right) \text{erfc}\left(\frac{h(\alpha t)^{1/2}}{k}\right)$$

with

$$\frac{h(\alpha t_m)^{1/2}}{k} = \frac{200\text{ W/m}^2 \cdot \text{K} (10^{-4}\text{ m}^2/\text{s} \times 400\text{ s})^{1/2}}{400\text{ W/m}\cdot\text{K}} = 0.1$$

$$T_s = T_m = T_i + (T_\infty - T_i) [1 - \exp(0.01) \text{erfc}(0.1)]$$

$$T_s = 25^\circ\text{C} + 275^\circ\text{C} [1 - 1.01 \times 0.888] = 53.5^\circ\text{C}.$$

<

COMMENTS: Use of the procedure to evaluate h from measurement of t_m necessitates iterative calculations.

PROBLEM 5.74

KNOWN: Irreversible thermal injury (cell damage) occurs in living tissue maintained at $T \geq 48^\circ\text{C}$ for a duration $\Delta t \geq 10\text{s}$.

FIND: (a) Extent of damage for 10 seconds of contact with machinery in the temperature range 50 to 100°C , (b) Temperature histories at selected locations in tissue ($x = 0.5, 1, 5\text{ mm}$) for a machinery temperature of 100°C .

SCHEMATIC:

ASSUMPTIONS: (1) Portion of worker's body modeled as semi-infinite medium, initially at a uniform temperature, 37°C , (2) Tissue properties are constant and equivalent to those of water at 37°C , (3) Negligible contact resistance.

PROPERTIES: Table A-6, Water, liquid ($T = 37^\circ\text{C} = 310\text{ K}$): $\rho = 1/\nu_f = 993.1\text{ kg/m}^3$, $c = 4178\text{ J/kg}\cdot\text{K}$, $k = 0.628\text{ W/m}\cdot\text{K}$, $\alpha = k/\rho c = 1.513 \times 10^{-7}\text{ m}^2/\text{s}$.

ANALYSIS: (a) For a given surface temperature -- suddenly applied -- the analysis is directed toward finding the skin depth x_b for which the tissue will be at $T_b \geq 48^\circ\text{C}$ for more than 10s? From Eq. 5.57,

$$\frac{T(x_b, t) - T_s}{T_i - T_s} = \text{erf} \left[\frac{x_b}{2(\alpha t)^{1/2}} \right] = \text{erf} [w].$$

For the two values of T_s , the left-hand side of the equation is

$$T_s = 100^\circ\text{C}: \frac{(48 - 100)^\circ\text{C}}{(37 - 100)^\circ\text{C}} = 0.825 \quad T_s = 50^\circ\text{C}: \frac{(48 - 50)^\circ\text{C}}{(37 - 50)^\circ\text{C}} = 0.154$$

The burn depth is

$$x_b = [w] 2(\alpha t)^{1/2} = [w] 2 \left(1.513 \times 10^{-7} \text{ m}^2/\text{s} \times t \right)^{1/2} = 7.779 \times 10^{-4} [w] t^{1/2}.$$

Continued...

PROBLEM 5.74 (Cont.)

Using Table B.2 to evaluate the error function and letting $t = 10\text{s}$, find x_b as

$$T_s = 100^\circ\text{C}: \quad x_b = 7.779 \times 10^{-4} [0.96](10\text{s})^{1/2} = 2.362 \times 10^{-3} \text{ m} = 2.36 \text{ mm} \quad <$$

$$T_s = 50^\circ\text{C}: \quad x_b = 7.779 \times 10^{-4} [0.137](10\text{s})^{1/2} = 3.37 \times 10^{-3} \text{ m} = 0.34 \text{ mm} \quad <$$

Recognize that tissue at this depth, x_b , has not been damaged, but will become so if T_s is maintained for the next 10s. We conclude that, for $T_s = 50^\circ\text{C}$, only superficial damage will occur for a contact period of 20s.

(b) Temperature histories at the prescribed locations are as follows.

The critical temperature of 48°C is reached within approximately 1s at $x = 0.5 \text{ mm}$ and within 7s at $x = 2 \text{ mm}$.

COMMENTS: Note that the burn depth x_b increases as $t^{1/2}$.

PROBLEM 5.75

KNOWN: Thermocouple location in thick slab. Initial temperature. Thermocouple measurement two minutes after one surface is brought to temperature of boiling water.

FIND: Thermal conductivity of slab material.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x , (2) Slab is semi-infinite medium, (3) Constant properties.

PROPERTIES: Slab material (given): $\rho = 2200 \text{ kg/m}^3$, $c = 700 \text{ J/kg}\cdot\text{K}$.

ANALYSIS: For the semi-infinite medium from Eq. 5.57,

$$\frac{T(x,t) - T_s}{T_i - T_s} = \text{erf} \left[\frac{x}{2(\alpha t)^{1/2}} \right]$$

$$\frac{65 - 100}{30 - 100} = \text{erf} \left[\frac{0.01 \text{ m}}{2(\alpha \times 120 \text{ s})^{1/2}} \right]$$

$$\text{erf} \left[\frac{0.01 \text{ m}}{2(\alpha \times 120 \text{ s})^{1/2}} \right] = 0.5.$$

From Appendix B, find for erf $w = 0.5$ that $w = 0.477$; hence,

$$\frac{0.01 \text{ m}}{2(\alpha \times 120 \text{ s})^{1/2}} = 0.477$$

$$(\alpha \times 120)^{1/2} = 0.0105$$

$$\alpha = 9.156 \times 10^{-7} \text{ m}^2/\text{s}.$$

It follows that since $\alpha = k/\rho c$,

$$k = \alpha \rho c$$

$$k = 9.156 \times 10^{-7} \text{ m}^2/\text{s} \times 2200 \text{ kg/m}^3 \times 700 \text{ J/kg}\cdot\text{K}$$

$$k = 1.41 \text{ W/m}\cdot\text{K}.$$

<

PROBLEM 5.76

KNOWN: Initial temperature, density and specific heat of a material. Convection coefficient and temperature of air flow. Time for embedded thermocouple to reach a prescribed temperature.

FIND: Thermal conductivity of material.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x , (2) Sample behaves as a semi-infinite medium, (3) Constant properties.

ANALYSIS: The thermal response of the sample is given by Case 3, Eq. 5.60,

$$\frac{T(x, t) - T_i}{T_\infty - T_i} = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right) - \left[\exp\left(\frac{hx}{k} + \frac{h^2 \alpha t}{k^2}\right)\right] \left[\text{erfc}\left(\frac{x}{2\sqrt{\alpha t}} + \frac{h\sqrt{\alpha t}}{k}\right)\right]$$

where, for $x = 0.01 \text{ m}$ at $t = 300 \text{ s}$, $[T(x, t) - T_i]/(T_\infty - T_i) = 0.533$. The foregoing equation must be solved iteratively for k , with $\alpha = k/\rho c_p$. The result is

$$k = 0.45 \text{ W/m}\cdot\text{K}$$

<

with $\alpha = 4.30 \times 10^{-7} \text{ m}^2/\text{s}$.

COMMENTS: The solution may be effected by inserting the *Transient Conduction/Semi-infinite Solid/Surface Conduction Model* of *IHT* into the work space and applying the *IHT Solver*. However, the ability to obtain a converged solution depends strongly on the initial guesses for k and α .

PROBLEM 5.77

KNOWN: Very thick plate, initially at a uniform temperature, T_i , is suddenly exposed to a surface convection cooling process (T_∞, h).

FIND: (a) Temperatures at the surface and 45 mm depth after 3 minutes, (b) Effect of thermal diffusivity and conductivity on temperature histories at $x = 0, 0.045$ m.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Plate approximates semi-infinite medium, (3) Constant properties, (4) Negligible radiation.

ANALYSIS: (a) The temperature distribution for a semi-infinite solid with surface convection is given by Eq. 5.60.

$$\frac{T(x, t) - T_i}{T_\infty - T_i} = \text{erfc}\left(\frac{x}{2(\alpha t)^{1/2}}\right) - \left[\exp\left(\frac{hx}{k} + \frac{h^2 \alpha t}{k^2}\right)\right] \left[\text{erfc}\left(\frac{x}{2(\alpha t)^{1/2}} + \frac{h(\alpha t)^{1/2}}{k}\right)\right].$$

At the surface, $x = 0$, and for $t = 3 \text{ min} = 180 \text{ s}$,

$$\begin{aligned} \frac{T(0, 180 \text{ s}) - 325^\circ \text{C}}{(15 - 325)^\circ \text{C}} &= \text{erfc}(0) - \left[\exp\left(0 + \frac{100^2 \text{ W}^2/\text{m}^4 \cdot \text{K}^2 \times 5.6 \times 10^{-6} \text{ m}^2/\text{s} \times 180 \text{ s}}{(20 \text{ W/m} \cdot \text{K})^2}\right)\right] \\ &\quad \times \left[\text{erfc}\left(0 + \frac{100 \text{ W/m}^2 \cdot \text{K} \left(5.6 \times 10^{-6} \text{ m}^2/\text{s} \times 180 \text{ s}\right)^{1/2}}{20 \text{ W/m} \cdot \text{K}}\right)\right] \\ &= 1 - [\exp(0.02520) \times \text{erfc } 0.159] = 1 - 1.02552 \times 1 - 0.178) \end{aligned}$$

$$T(0, 180 \text{ s}) = 325^\circ \text{C} - (15 - 325)^\circ \text{C} \cdot (1 - 1.0255 \times 0.822)$$

$$T(0, 180 \text{ s}) = 325^\circ \text{C} - 49.3^\circ \text{C} = 276^\circ \text{C} .$$

At the depth $x = 0.045$ m, with $t = 180 \text{ s}$,

$$\begin{aligned} \frac{T(0.045 \text{ m}, 180 \text{ s}) - 325^\circ \text{C}}{(15 - 325)^\circ \text{C}} &= \text{erfc}\left(\frac{0.045 \text{ m}}{2(5.6 \times 10^{-6} \text{ m}^2/\text{s} \times 180 \text{ s})^{1/2}}\right) - \left[\exp\left(\frac{100 \text{ W/m}^2 \cdot \text{K} \times 0.045 \text{ m}}{20 \text{ W/m} \cdot \text{K}} + 0.02520\right)\right] \\ &\quad \times \left[\text{erfc}\left(\frac{0.045 \text{ m}}{2(5.6 \times 10^{-6} \text{ m}^2/\text{s} \times 180 \text{ s})^{1/2}} + 0.159\right)\right] \\ &= \text{fc}(0.7087) + \exp(0.225 + 0.0252) \times \text{erfc } 0.7087 + 0.159) . \end{aligned}$$

$$T(0.045 \text{ m}, 180 \text{ s}) = 325^\circ \text{C} + (15 - 325)^\circ \text{C} [(1 - 0.684) - 1.284(1 - 0.780)] = 315^\circ \text{C}$$

Continued...

PROBLEM 5.77 (Cont.)

(b) The IHT Transient Conduction Model for a Semi-Infinite Solid was used to generate temperature histories, and for the two locations the effects of varying α and k are as follows.

For fixed k , increasing α corresponds to a reduction in the thermal capacitance per unit volume (ρc_p) of the material and hence to a more pronounced reduction in temperature at both surface and interior locations. Similarly, for fixed α , decreasing k corresponds to a reduction in ρc_p and hence to a more pronounced decay in temperature.

COMMENTS: In part (a) recognize that Fig. 5.8 could also be used to determine the required temperatures.

PROBLEM 5.78

KNOWN: Thick oak wall, initially at a uniform temperature of 25°C, is suddenly exposed to combustion products at 800°C with a convection coefficient of 20 W/m²·K.

FIND: (a) Time of exposure required for the surface to reach an ignition temperature of 400°C, (b) Temperature distribution at time t = 325s.

SCHEMATIC:

ASSUMPTIONS: (1) Oak wall can be treated as semi-infinite solid, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation.

PROPERTIES: Table A-3, Oak, cross grain (300 K): $\rho = 545\text{ kg/m}^3$, $c = 2385\text{ J/kg}\cdot\text{K}$, $k = 0.17\text{ W/m}\cdot\text{K}$, $\alpha = k/\rho c = 0.17\text{ W/m}\cdot\text{K}/545\text{ kg/m}^3 \times 2385\text{ J/kg}\cdot\text{K} = 1.31 \times 10^{-7}\text{ m}^2/\text{s}$.

ANALYSIS: (a) This situation corresponds to Case 3 of Figure 5.7. The temperature distribution is given by Eq. 5.60 or by Figure 5.8. Using the figure with

$$\frac{T(0, t) - T_i}{T_\infty - T_i} = \frac{400 - 25}{800 - 25} = 0.48 \quad \text{and} \quad \frac{x}{2(\alpha t)^{1/2}} = 0$$

we obtain $h(\alpha t)^{1/2}/k \approx 0.75$, in which case $t \approx (0.75k/h\alpha^{1/2})^2$. Hence,

$$t \approx \left(0.75 \times 0.17\text{ W/m}\cdot\text{K} / 20\text{ W/m}^2\cdot\text{K} \left(1.31 \times 10^{-7}\text{ m}^2/\text{s} \right)^{1/2} \right)^2 = 310\text{s} \quad <$$

(b) Using the IHT Transient Conduction Model for a Semi-infinite Solid, the following temperature distribution was generated for t = 325s.

The temperature decay would become more pronounced with decreasing α (decreasing k , increasing ρc_p) and in this case the penetration depth of the heating process corresponds to $x \approx 0.025\text{ m}$ at 325s.

COMMENTS: The result of part (a) indicates that, after approximately 5 minutes, the surface of the wall will ignite and combustion will ensue. Once combustion has started, the present model is no longer appropriate.

PROBLEM 5.79

KNOWN: Thickness, initial temperature and thermophysical properties of concrete firewall. Incident radiant flux and duration of radiant heating. Maximum allowable surface temperatures at the end of heating.

FIND: If maximum allowable temperatures are exceeded.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in wall, (2) Validity of semi-infinite medium approximation, (3) Negligible convection and radiative exchange with the surroundings at the irradiated surface, (4) Negligible heat transfer from the back surface, (5) Constant properties.

ANALYSIS: The thermal response of the wall is described by Eq. (5.59)

$$T(x, t) = T_i + \frac{2 q_o'' (\alpha t / \pi)^{1/2}}{k} \exp\left(\frac{-x^2}{4\alpha t}\right) - \frac{q_o'' x}{k} \operatorname{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

where, $\alpha = k / \rho c_p = 6.92 \times 10^{-7} \text{ m}^2 / \text{s}$ and for $t = 30 \text{ min} = 1800 \text{ s}$, $2q_o'' (\alpha t / \pi)^{1/2} / k = 284.5 \text{ K}$. Hence, at $x = 0$,

$$T(0, 30 \text{ min}) = 25^\circ\text{C} + 284.5^\circ\text{C} = 309.5^\circ\text{C} < 325^\circ\text{C} \quad <$$

At $x = 0.25 \text{ m}$, $(-x^2 / 4\alpha t) = -12.54$, $q_o'' x / k = 1,786 \text{ K}$, and $x / 2(\alpha t)^{1/2} = 3.54$. Hence,

$$T(0.25 \text{ m}, 30 \text{ min}) = 25^\circ\text{C} + 284.5^\circ\text{C} \left(3.58 \times 10^{-6}\right) - 1786^\circ\text{C} \times (\sim 0) \approx 25^\circ\text{C} \quad <$$

Both requirements are met.

COMMENTS: The foregoing analysis is conservative since heat transfer at the irradiated surface due to convection and net radiation exchange with the environment have been neglected. If the emissivity of the surface and the temperature of the surroundings are assumed to be $\epsilon = 1$ and $T_{\text{sur}} = 298 \text{ K}$, radiation exchange at $T_s = 309.5^\circ\text{C}$ would be $q_{\text{rad}}'' = \epsilon \sigma (T_s^4 - T_{\text{sur}}^4) = 6,080 \text{ W} / \text{m}^2 \cdot \text{K}$, which is significant ($\sim 60\%$ of the prescribed radiation).

PROBLEM 5.80

KNOWN: Initial temperature of copper and glass plates. Initial temperature and properties of finger.

FIND: Whether copper or glass feels cooler to touch.

SCHEMATIC:

ASSUMPTIONS: (1) The finger and the plate behave as semi-infinite solids, (2) Constant properties, (3) Negligible contact resistance.

PROPERTIES: Skin (given): $\rho = 1000 \text{ kg/m}^3$, $c = 4180 \text{ J/kg}\cdot\text{K}$, $k = 0.625 \text{ W/m}\cdot\text{K}$; Table A-1 ($T = 300K$), Copper: $\rho = 8933 \text{ kg/m}^3$, $c = 385 \text{ J/kg}\cdot\text{K}$, $k = 401 \text{ W/m}\cdot\text{K}$; Table A-3 ($T = 300K$), Glass: $\rho = 2500 \text{ kg/m}^3$, $c = 750 \text{ J/kg}\cdot\text{K}$, $k = 1.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: Which material feels cooler depends upon the contact temperature T_s given by Equation 5.63. For the three materials of interest,

$$\begin{aligned}(k\rho c)_{\text{skin}}^{1/2} &= (0.625 \times 1000 \times 4180)^{1/2} = 1,616 \text{ J/m}^2 \cdot \text{K} \cdot \text{s}^{1/2} \\(k\rho c)_{\text{cu}}^{1/2} &= (401 \times 8933 \times 385)^{1/2} = 37,137 \text{ J/m}^2 \cdot \text{K} \cdot \text{s}^{1/2} \\(k\rho c)_{\text{glass}}^{1/2} &= (1.4 \times 2500 \times 750)^{1/2} = 1,620 \text{ J/m}^2 \cdot \text{K} \cdot \text{s}^{1/2}.\end{aligned}$$

Since $(k\rho c)_{\text{cu}}^{1/2} \gg (k\rho c)_{\text{glass}}^{1/2}$, the copper will feel much cooler to the touch. From Equation 5.63,

$$T_s = \frac{(k\rho c)_A^{1/2} T_{A,i} + (k\rho c)_B^{1/2} T_{B,i}}{(k\rho c)_A^{1/2} + (k\rho c)_B^{1/2}}$$

$$T_{s(\text{cu})} = \frac{1,616(310) + 37,137(300)}{1,616 + 37,137} = 300.4 \text{ K} \quad <$$

$$T_{s(\text{glass})} = \frac{1,616(310) + 1,620(300)}{1,616 + 1,620} = 305.0 \text{ K} \quad <$$

COMMENTS: The extent to which a material's temperature is affected by a change in its thermal environment is inversely proportional to $(k\rho c)^{1/2}$. Large k implies an ability to spread the effect by conduction; large ρc implies a large capacity for thermal energy storage.

PROBLEM 5.81

KNOWN: Initial temperatures, properties, and thickness of two plates, each insulated on one surface.

FIND: Temperature on insulated surface of one plate at a prescribed time after they are pressed together.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible contact resistance.

PROPERTIES: Stainless steel (given): $\rho = 8000 \text{ kg/m}^3$, $c = 500 \text{ J/kg}\cdot\text{K}$, $k = 15 \text{ W/m}\cdot\text{K}$.

ANALYSIS: At the instant that contact is made, the plates behave as semi-infinite slabs and, since the (ρkc) product is the same for the two plates, Equation 5.63 yields a surface temperature of

$$T_s = 350 \text{ K}.$$

The interface will remain at this temperature, even after thermal effects penetrate to the insulated surfaces. The transient response of the hot wall may therefore be calculated from Equations 5.40 and 5.41. At the insulated surface ($x^* = 0$), Equation 5.41 yields

$$\frac{T_o - T_s}{T_i - T_s} = C_1 \exp(-\zeta_1^2 Fo)$$

where, in principle, $h \rightarrow \infty$ and $T_\infty \rightarrow T_s$. From Equation 5.39c, $Bi \rightarrow \infty$ yields $\zeta_1 = 1.5707$, and from Equation 5.39b

$$C_1 = \frac{4 \sin \zeta_1}{2 \zeta_1 + \sin(2 \zeta_1)} = 1.273$$

Also,
$$Fo = \frac{\alpha t}{L^2} = \frac{3.75 \times 10^{-6} \text{ m}^2/\text{s} (60 \text{ s})}{(0.02 \text{ m})^2} = 0.563.$$

Hence,
$$\frac{T_o - 350}{400 - 350} = 1.273 \exp(-1.5707^2 \times 0.563) = 0.318$$

$$T_o = 365.9 \text{ K}.$$

<

COMMENTS: Since $Fo > 0.2$, the one-term approximation is appropriate.

PROBLEM 5.82

KNOWN: Thickness and properties of liquid coating deposited on a metal substrate. Initial temperature and properties of substrate.

FIND: (a) Expression for time required to completely solidify the liquid, (b) Time required to solidify an alumina coating.

SCHEMATIC:

ASSUMPTIONS: (1) Substrate may be approximated as a semi-infinite medium in which there is one-dimensional conduction, (2) Solid and liquid alumina layers remain at fusion temperature throughout solidification (negligible resistance to heat transfer by conduction through solid), (3) Negligible contact resistance at the coating/substrate interface, (4) Negligible solidification contraction, (5) Constant properties.

ANALYSIS: (a) Performing an energy balance on the solid layer, whose thickness S increases with t , the latent heat released at the solid/liquid interface must be balanced by the rate of heat conduction into the solid. Hence, per unit surface area,

$$\rho h_{sf} \frac{dS}{dt} = q''_{cond} \quad \text{where, from Eq. 5.58, } q''_{cond} = k(T_f - T_i)/(\pi \alpha t)^{1/2}. \quad \text{It follows that}$$

$$\rho h_{sf} \frac{dS}{dt} = \frac{k_s (T_f - T_i)}{\pi \alpha_s t^{1/2}}$$

$$\int_0^\delta dS = \frac{k_s (T_f - T_i)}{\rho h_{sf} (\pi \alpha_s)^{1/2}} \int_0^t \frac{dt}{t^{1/2}}$$

$$\delta = \frac{2k_s}{(\pi \alpha_s)^{1/2}} \left(\frac{T_f - T_i}{\rho h_{sf}} \right) t^{1/2}$$

$$t = \frac{\pi \alpha_s}{4k_s^2} \left(\frac{\delta \rho h_{sf}}{T_f - T_i} \right)^2$$

(b) For the prescribed conditions,

$$t = \frac{\pi (4 \times 10^{-5} \text{ m}^2/\text{s})}{4 (120 \text{ W/m}\cdot\text{K})^2} \left(\frac{0.002 \text{ m} \times 3970 \text{ kg/m}^3 \times 3.577 \times 10^6 \text{ J/kg}}{2018 \text{ K}} \right)^2 = 0.43$$

COMMENTS: If solidification occurs over a short time resulting in a change of the solid's microstructure (relative to slow solidification), it is termed *rapid solidification*. See Problem 5.32.

PROBLEM 5.83

KNOWN: Properties of mold wall and a solidifying metal.

FIND: (a) Temperature distribution in mold wall at selected times, (b) Expression for variation of solid layer thickness.

SCHEMATIC:

ASSUMPTIONS: (1) Mold wall may be approximated as a semi-infinite medium in which there is one-dimensional conduction, (2) Solid and liquid metal layers remain at fusion temperature throughout solidification (negligible resistance to heat transfer by conduction through solid), (3) Negligible contact resistance at mold/metal interface, (4) Constant properties.

ANALYSIS: (a) As shown in schematic (b), the temperature remains nearly uniform in the metal (at T_f) throughout the process, while both the temperature and temperature penetration increase with time in the mold wall.

(b) Performing an energy balance for a control surface about the solid layer, the latent energy released due to solidification at the solid/liquid interface is balanced by heat conduction into the solid, $q''_{lat} = q''_{cond}$, where $q''_{lat} = \rho h_{sf} dS/dt$ and q''_{cond} is given by Eq. 5.58. Hence,

$$\rho h_{sf} \frac{dS}{dt} = \frac{k_w (T_f - T_i)}{(\pi \alpha_w t)^{1/2}}$$

$$\int_0^S dS = \frac{k_w (T_f - T_i)}{\rho h_{sf} (\pi \alpha_w)^{1/2}} \int_0^t \frac{dt}{t^{1/2}}$$

$$S = \frac{2k_w (T_f - T_i)}{\rho h_{sf} (\pi \alpha_w)^{1/2}} t^{1/2}$$

<

COMMENTS: The analysis of part (b) would only apply until the temperature field penetrates to the exterior surface of the mold wall, at which point, it may no longer be approximated as a semi-infinite medium.

PROBLEM 5.84

KNOWN: Diameter and initial temperature of two Inconel rods. Amplitude and frequency of motion of upper rod. Coefficient of friction.

FIND: Compressive force required to bring rod to melting point in 3 seconds.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss from surfaces of rods, (2) Rods are effectively semi-infinite, (3) Frictional heat generation can be treated as constant in time, (4) Constant properties.

PROPERTIES: Table A.1, Inconel X-750: $T_m = 1665 \text{ K}$, $\bar{T} = (T_i + T_m)/2 = (293 + 1665)/2 = 979 \text{ K}$, $k = 23.6 \text{ W/m}\cdot\text{K}$, $c_p = 618 \text{ J/kg}\cdot\text{K}$, $\rho = 8510 \text{ kg/m}^3$, $\alpha = k/\rho c_p = 4.49 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: We begin by expressing the frictional heat flux in terms of the unknown compressive force, F_n .

$$q'' = -\frac{\vec{F}_t \cdot \vec{V}}{A} = \frac{|\mu F_n V|}{A} = \frac{|\mu F_n|}{A} \frac{dd}{dt} = \frac{|\mu F_n|}{A} a\omega |\sin \omega t|$$

In the above equation, use has been made of the fact that the frictional force always opposes the direction of motion, therefore $\vec{F}_t \cdot \vec{V} = -|F_t V|$. The average value of the heat flux is found by integrating over one period of $|\sin \omega t|$, namely π/ω :

$$\bar{q}_s'' = \frac{\omega}{\pi} \int_0^{\pi/\omega} \frac{\mu F_n a \omega}{A} |\sin \omega t| dt = -\frac{1}{\pi} \frac{\mu F_n a \omega}{A} \cos \omega t \bigg|_0^{\pi/\omega} = \frac{2\mu F_n a \omega}{\pi A} \quad (1)$$

Continued...

PROBLEM 5.84 (Cont.)

Note that $A = \pi D^2/2$, because heat conducts in both directions. We can find the surface temperature from Eq. 5.59 for the temperature distribution in a semi-infinite solid with uniform surface heat flux. Evaluating that equation at $x = 0$ yields

$$T_s - T_i = \frac{2\bar{q}_s''(\alpha t/\pi)^{1/2}}{k} \quad (2)$$

With T_s equal to the melting temperature, we can solve for \bar{q}_s'' :

$$\begin{aligned} \bar{q}_s'' &= \frac{k(T_s - T_i)}{2} \left(\frac{\pi}{\alpha t} \right)^{1/2} \\ &= \frac{23.6 \text{ W/m} \cdot \text{K} (1665 \text{ K} - 293 \text{ K})}{2} \left(\frac{\pi}{4.49 \times 10^{-6} \text{ m}^2/\text{s} \times 3 \text{ s}} \right)^{1/2} \\ &= 7.82 \times 10^6 \text{ W/m}^2 \end{aligned}$$

Then we can solve for F_n from Eq. (1):

$$F_n = \frac{\bar{q}_s'' \pi A}{2\mu a \omega} = \frac{7.82 \times 10^6 \text{ W/m}^2 \times \pi \times \pi \times (0.04 \text{ m})^2 / 2}{2 \times 0.3 \times 0.002 \text{ m} \times 1000 \text{ rad/s}} = 51.4 \text{ kN} \quad <$$

PROBLEM 5.85

KNOWN: Above ground swimming pool diameter and temperature. Ground temperature.

FIND: (a) Rate of heat transfer from pool to ground after 10 hours, and (b) Time for heat transfer rate to reach within 10% of its steady-state value.

SCHEMATIC:

ASSUMPTIONS: (1) Temperature of ground underneath pool quickly reaches 20°C when heater is turned on, and remains constant, (2) Negligible heat loss from surface of ground to surrounding air.

PROPERTIES: Table A.3, Soil (≈ 300 K): $\rho = 2050$ kg/m³, $k = 0.52$ W/m·K, $c_p = 1840$ J/kg·K, $\alpha = 1.38 \times 10^{-7}$ m²/s.

ANALYSIS: (a) Since there is no heat loss from the ground, the surface can be viewed as a symmetry plane, and the footprint of the pool can be seen as a constant temperature disk in infinite surroundings. Referring to Table 5.2a, Exterior Cases, Various Shapes, and Table 4.1, Case 13 we have

$$q^* = \frac{1}{\sqrt{\pi Fo}} + q_{ss}^* = \frac{1}{\sqrt{\pi Fo}} + \frac{2\sqrt{2}}{\pi} \quad (1)$$

with $Fo = \alpha t / L_c^2$, $L_c = (A_s / 4\pi)^{1/2}$, and $A_s = \pi D^2 / 4$. Thus

$$L_c = (D^2 / 8)^{1/2} = 5 \text{ m} / \sqrt{8} = 1.77 \text{ m}$$

$$Fo = \alpha t / L_c^2 = (1.38 \times 10^{-7} \text{ m}^2/\text{s} \times 10 \text{ h} \times 3600 \text{ s/h}) / (1.77 \text{ m})^2 = 1.59 \times 10^{-3}$$

Thus

$$q^* = 15.1 = \frac{q_s'' L_c}{k(T_s - T_i)}$$

Thus

$$\begin{aligned} q_s &= q_s'' A_s = \frac{k A_s (T_s - T_i)}{L_c} q^* \\ &= \left[0.52 \text{ W/m} \cdot \text{K} \times \pi \times (5 \text{ m})^2 / 4 \times (20^\circ\text{C} - 10^\circ\text{C}) / 1.77 \text{ m} \right] \times 15.1 \\ &= 116 \text{ W} \times 15.1 = 1739 \text{ W} \end{aligned}$$

Continued...

PROBLEM 5.85 (Cont.)

Since this is the heat transfer rate from the disk to infinite surroundings, the heat rate from the disk to the ground is:

$$q_{\text{gr}} = q_s/2 = 870 \text{ W}$$

<

(b) From Equation (1) we see that the dimensionless heat rate, q^* , is greater than the steady-state dimensionless heat rate, q_{ss}^* . We wish to find the time at which q^* is 10% greater than q_{ss}^* , that is

$$q^* = \frac{1}{\sqrt{\pi Fo}} + q_{\text{ss}}^* = 1.1(q_{\text{ss}}^*)$$

$$\frac{1}{\sqrt{\pi Fo}} = 0.1 q_{\text{ss}}^* = 0.1 \frac{2\sqrt{2}}{\pi}$$

Thus

$$Fo = \left[\frac{\pi}{0.1(2\sqrt{2})} \right]^2 \frac{1}{\pi} = 39.3$$

and

$$\begin{aligned} t &= Fo L_c^2 / \alpha \\ &= 39.3 (1.77 \text{ m})^2 / 1.38 \times 10^{-7} \text{ m}^2/\text{s} \\ &= 8.9 \times 10^8 \text{ s} = 28.2 \text{ years} \end{aligned}$$

<

COMMENTS: The low thermal diffusivity of the soil and the large pool dimensions result in a very long time to reach steady-state. Therefore, it is not appropriate to treat the problem as steady-state.

PROBLEM 5.86

KNOWN: Thickness and properties of DVD disk. Laser spot size and power.

FIND: Time needed to raise the storage material from 300 K to 1000 K.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible contact resistances at the interfaces, (2) Infinite medium, (3) Polycarbonate is transparent to laser irradiation, (4) Polycarbonate is opaque to radiation from the heated spot, (5) Spatially-uniform laser power, (6) Motion of disk does not affect the thermal response, (7) Infinitely thin storage material, (8) Negligible nanoscale heat transfer effects.

PROPERTIES: Polycarbonate (given): $k = 0.21 \text{ W/m}\cdot\text{K}$, $\rho = 1200 \text{ kg/m}^3$, $c_p = 1260 \text{ J/kg}\cdot\text{K}$.
Storage material (given): $\alpha_r = 0.8$

ANALYSIS: The heat transferred from the irradiated storage material is

$$q = \alpha_r P \quad (1)$$

From Case 13 of Table 4.1,

$$A_s = \pi D^2/2 \quad (2)$$

From Table 5.2b for $Fo < 0.2$,

$$q^*(Fo) = \frac{q_s'' L_c}{k(T_s - T_i)} = \frac{1}{2} \sqrt{\frac{\pi}{Fo}} + \frac{\pi}{4} \quad (3a)$$

From Table 5.2b for $Fo \geq 0.2$

$$q^*(Fo) = \frac{q_s'' L_c}{k(T_s - T_i)} = \frac{0.77}{\sqrt{Fo}} + \frac{2\sqrt{2}}{\pi} \quad (3b)$$

$$\text{where } L_c = (A_s/4\pi)^{1/2} = D/\sqrt{8}; \quad q_s'' = \frac{q}{A_s} \quad (4)$$

$$\text{and } Fo = \alpha t/L_c^2 = 8\alpha t/D^2 \quad (5)$$

$$\text{with } \alpha = k/\rho c = 0.21 \text{ W/m}\cdot\text{K}/(1200 \text{ kg/m}^3 \times 1260 \text{ J/kg}\cdot\text{K}) = 139 \times 10^{-9} \text{ m}^2/\text{s},$$

Continued...

PROBLEM 5.86 (Cont.)

$$\text{and } \frac{q_s'' L_c}{k(T_s - T_c)} = \frac{2P\alpha_r}{\pi D \sqrt{8k}(T_s - T_i)}$$
$$= \frac{2 \times 1 \times 10^{-3} \text{ W} \times 0.8}{\pi \times 0.4 \times 10^{-6} \times \sqrt{8} \times 0.21 \text{ W/m} \cdot \text{K} \times (1000 - 300) \text{ K}} = 3.0623$$

Equations (3a) and (3b) yield

For $Fo < 0.2$, $Fo = 0.151$

For $Fo \geq 0.2$, $Fo = 0.127$

Therefore, $Fo = 0.152$

<

From Equation (5),

$$t = \frac{FoD^2}{8\alpha} = \frac{0.151 \times (0.4 \times 10^{-6} \text{ m})^2}{8 \times 139 \times 10^{-9} \text{ m}^2/\text{s}} = 21.8 \times 10^{-9} \text{ s} = 21.8 \text{ ns}$$

<

COMMENTS: The actual heating rate will be slightly longer due to the finite thickness of the storage medium.

PROBLEM 5.87

KNOWN: Mass and initial temperatures of frozen ground beef. Rate of microwave power absorbed in packaging material.

FIND: Time for beef adjacent to packaging to reach 0°C.

SCHEMATIC:

ASSUMPTIONS: (1) Beef has properties of ice, (2) Radiation and convection to environment are neglected, (3) Constant properties, (4) Packaging material has negligible heat capacity.

PROPERTIES: Table A.3, Ice (≈ 273 K): $\rho = 920$ kg/m³, $c = 2040$ J/kg·K, $k = 1.88$ W/m·K.

ANALYSIS: Neglecting radiation and convection losses, all the power absorbed in the packaging material conducts into the beef. The surface heat flux is

$$q_s'' = \frac{\dot{q}}{A_s} = \frac{0.5P}{4\pi R^2}$$

The radius of the sphere can be found from knowledge of the mass and density:

$$m = \rho V = \rho \frac{4}{3} \pi r_o^3$$

$$R = \left(\frac{3}{4\pi} \frac{m}{\rho} \right)^{1/3} = \left(\frac{3}{4\pi} \frac{1 \text{ kg}}{920 \text{ kg/m}^3} \right)^{1/3} = 0.0638 \text{ m}$$

Thus

$$q_s'' = \frac{0.5(1000 \text{ W})}{4\pi(0.0638 \text{ m})^2} = 9780 \text{ W/m}^2$$

For a constant surface heat flux, the relationship in Table 5.2b, Interior Cases, sphere, can be used. We begin by calculating q^* for $T_s = 0^\circ\text{C}$.

$$q^* = \frac{q_s'' r_o}{k(T_s - T_i)} = \frac{9780 \text{ W/m}^2 \times 0.0638 \text{ m}}{1.88 \text{ W/m} \cdot \text{K}(0^\circ\text{C} - (-20^\circ\text{C}))} = 16.6$$

We proceed to solve for Fo. Assuming that $Fo < 0.2$, we have

$$q^* \cong \frac{1}{2} \sqrt{\frac{\pi}{Fo}} - \frac{\pi}{4}$$

Continued....

PROBLEM 5.87 (Cont.)

$$Fo = \pi \left[2(q^* + \frac{\pi}{4}) \right]^{-2} = 0.0026$$

Since this is less than 0.2, our assumption was correct. Finally we can solve for the time:

$$\begin{aligned} t &= Fo r_o^2 / \alpha = Fo r_o^2 \rho c / k \\ &= (0.0026 \times (0.0638 \text{ m})^2 \times 920 \text{ kg/m}^3 \times 2040 \text{ J/kg} \cdot \text{K}) / (1.88 \text{ W/m} \cdot \text{K}) \\ &= 10.6 \text{ s} \end{aligned}$$

<

COMMENTS: At the minimum surface temperature of -20°C , with $T_\infty = 30^\circ\text{C}$ and $h = 15 \text{ W/m}^2 \cdot \text{K}$ from Problem 5.33, the convection heat flux is 750 W/m^2 , which is less than 8% of the microwave heat flux. The radiation heat flux would likely be less, depending on the temperature of the oven walls.

PROBLEM 5.88

KNOWN: Thickness and initial temperature of composite skin. Properties of material when intact and when delaminated. Imposed surface heat flux.

FIND: Surface temperature of (a) intact material and (b) delaminated material, after 10 and 100 seconds.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat conduction, (2) Bottom surface adiabatic, (3) Constant and uniform properties, (4) Negligible convective and radiative losses.

ANALYSIS:

(a) The situation is equivalent to a plane wall of thickness $2L$ with heat flux at both surfaces. We use Table 5.2b, Interior Cases, Plane Wall of thickness $2L$. We first calculate Fo for the intact case at $t = 20 \text{ s}$.

$$\begin{aligned}
 Fo &= \frac{\alpha t}{L^2} = \frac{k_1 t}{\rho c L^2} \\
 &= \frac{1.6 \text{ W/m}\cdot\text{K} \times 10 \text{ s}}{1200 \text{ kg/m}^3 \times 1200 \text{ J/kg}\cdot\text{K} \times (0.015 \text{ m})^2} \\
 &= 0.0494
 \end{aligned}$$

Since $Fo < 0.2$,

$$q^* \cong \frac{1}{2} \sqrt{\frac{\pi}{Fo}} = \frac{1}{2} \sqrt{\frac{\pi}{0.0494}} = 3.99$$

Thus

$$\begin{aligned}
 T_{s,1}(10 \text{ s}) &= T_i + q_s'' L / k_1 q^* \\
 &= 20^\circ\text{C} + 5000 \text{ W/m}^2 \times 0.015 \text{ m} / (1.6 \text{ W/m}\cdot\text{K} \times 3.99) \\
 &= 31.8^\circ\text{C}
 \end{aligned}$$

<

At $t = 100 \text{ s}$, $Fo = 0.494 > 0.2$, thus

$$q^* \cong \left[Fo + \frac{1}{3} \right]^{-1} = 1.21$$

Continued...

PROBLEM 5.88 (Cont.)

And

$$\begin{aligned} T_{s,1}(100 \text{ s}) &= T_i + q_s'' L / k_1 q^* \\ &= 20^\circ\text{C} + 5000 \text{ W/m}^2 \times 0.015 \text{ m} / (1.6 \text{ W/m} \cdot \text{K} \times 1.21) \\ &= 58.8^\circ\text{C} \end{aligned} \quad <$$

(b) Repeating the calculations for $k_2 = 1.1 \text{ W/m} \cdot \text{K}$, we find

$$\begin{aligned} T_{s,2}(10 \text{ s}) &= 34.2^\circ\text{C} < \\ T_{s,2}(100 \text{ s}) &= 65.9^\circ\text{C} < \end{aligned}$$

COMMENTS: (1) For $t = 10 \text{ s}$, the Fourier number is less than 0.2, and the skin behaves as if it were semi-infinite. However for $t = 100 \text{ s}$, the heat has penetrated sufficiently far so that the presence of the insulated bottom surface affects the heat transfer. The surface temperature is higher than it would be for a semi-infinite solid.

(2) The surface temperatures are sufficiently different for the intact and delaminated cases so that detection is possible. The difference increases with increasing heating time, but if the heating time is too long the elevated temperature will damage the material.

(3) We have assumed that thermal conductivity is uniform, but in reality it will be different in intact and delaminated regions. In particular, if the delamination is near the bottom surface, use of a short heating time may not detect the damage because heat hasn't penetrated significantly into the damaged region.

(4) Convective and radiative losses may not be negligible.

PROBLEM 5.89

KNOWN: Energy generation rate within a buried spherical container of known size.

FIND: Time needed for the surface of the sphere to come within 10 degrees Celsius of the steady-state temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Infinite medium, (2) Constant properties, (3) Negligible contact resistance between the sphere and the soil.

PROPERTIES: Table A.3, soil (300 K): $k = 0.52 \text{ W/m}\cdot\text{K}$, $\rho = 2050 \text{ kg/m}^3$, $c_p = 1840 \text{ J/kg}\cdot\text{K}$.

ANALYSIS: The steady-state temperature difference may be obtained from case 12 of Table 4.1 with $L_c = (A_s/4\pi)^{1/2} = (\pi D^2/4\pi)^{1/2} = D/2$

$$q = kA_s(T_{1,ss} - T_2) = 0.52 \text{ W/m}\cdot\text{K} \times \pi \times (2\text{m})^2 \times (T_{1,ss} - T_2) = 500 \text{ W}$$

from which we find

$$T_{1,ss} - T_2 = 76.52^\circ\text{C}$$

Therefore, at the time of interest, $T_1 - T_2 = 76.52^\circ\text{C} - 10^\circ\text{C} = 66.52^\circ\text{C}$

From Table 5.2b, sphere, exterior case,

$$q^*(Fo) = \frac{q(D/2)}{\pi D^2 k (T_1 - T_2)} = \frac{1}{[1 - \exp(Fo) \operatorname{erfc}(Fo^{1/2})]}$$

$$\text{or } \frac{1}{[1 - \exp(Fo) \operatorname{erfc}(Fo^{1/2})]} = \frac{500 \text{ W}}{2\pi \times 2 \text{ m} \times 0.52 \text{ W/m}\cdot\text{K} \times 66.52\text{K}} = 1.15$$

Solving for Fo yields $Fo = 17.97$.

Knowing $\alpha = k/\rho c_p = 0.52 \text{ W/m}\cdot\text{K} / (1050 \text{ kg/m}^3 \times 1840 \text{ J/kg}\cdot\text{K}) = 1.379 \times 10^{-7} \text{ m}^2/\text{s}$

$$t = \frac{Fo \times (D/2)^2}{\alpha} = \frac{Fo D^2}{4\alpha} = \frac{17.97 \times (2 \text{ m})^2}{4 \times 1.379 \times 10^{-7} \text{ m}^2/\text{s}}$$

$$t = 1.303 \times 10^8 \text{ s} \times \frac{1 \text{ day}}{24 \text{ h}} \times \frac{1 \text{ h}}{3600 \text{ s}} \times \frac{1 \text{ year}}{365 \text{ days}} = 4.13 \text{ years.} \quad <$$

COMMENTS: The time to reach the steady-state is significant. In practice, it is often difficult to ascertain when steady-state is achieved due to the slow thermal response time of many systems.

PROBLEM 5.90

KNOWN: Dimensions of a fissure in limestone. Velocity of air flow through fissure and corresponding convection coefficient. Periodic variation of limestone surface temperature.

FIND: (a) Maximum and minimum values of air temperature near inlet. (b) Maximum heat flux to air and corresponding inlet and outlet temperatures. (c) Air outlet temperatures corresponding to maximum and minimum inlet temperatures. (d) Plot the inlet air and limestone surface temperatures and the heat transfer rate over a 24 hour period. (e) Required thickness for limestone to be viewed as semi-infinite.

SCHEMATIC:

ASSUMPTIONS: (1) Limestone can be treated as semi-infinite, (2) Variation of limestone surface temperature is sinusoidal, (3) Conduction in limestone is one-dimensional in the direction perpendicular to the surface.

PROPERTIES: Table A.3, Limestone ($T = 300 \text{ K}$): $\rho = 2320 \text{ kg/m}^3$, $k = 2.15 \text{ W/m}\cdot\text{K}$, $c_p = 810 \text{ J/kg}\cdot\text{K}$, $\alpha = k/\rho c_p = 1.14 \times 10^{-6} \text{ m}^2/\text{s}$. Table A.4, Air (300 K): $\rho_a = 1.1614 \text{ kg/m}^3$, $c_{pa} = 1007 \text{ J/kg}\cdot\text{K}$.

ANALYSIS:

(a) For a sinusoidal surface temperature variation, $T_s = T_i + \Delta T \sin \omega t$, the surface heat flux is given by Equation 5.70:

$$q_s''(t) = k\Delta T \sqrt{\omega/\alpha} \sin(\omega t + \pi/4) \quad (1)$$

Here this must equal the heat flux by convection from the air near the inlet, that is,

$$q_s''(t) = h(T_{in} - T_s)$$

Thus

$$\begin{aligned} T_{in} &= T_s + q_s''/h \\ &= T_i + \Delta T \sin \omega t + (k\Delta T \sqrt{\omega/\alpha}/h) \sin(\omega t + \pi/4) \end{aligned} \quad (2)$$

where $\omega = 2\pi/(24 \text{ h} \times 3600 \text{ s/h}) = 7.27 \times 10^{-5} \text{ s}^{-1}$. *IHT* was used to solve for and plot T_{in} over a
Continued...

PROBLEM 5.90 (Cont.)

24 hour period, and the Explore function was used to identify the maximum and minimum values:

$$T_{\text{in,max}} = 32^\circ\text{C} \quad \text{at} \quad t = 1.5 \times 10^4 \text{ s} \quad <$$

$$T_{\text{in,min}} = 22^\circ\text{C} \quad \text{at} \quad t = 5.8 \times 10^4 \text{ s} \quad <$$

(b) The heat flux to the air is given by

$$q_a'' = -q_s'' = -k\Delta T\sqrt{\omega/\alpha} \sin(\omega t + \pi/4) \quad (3)$$

and this is maximum when $\omega t + \pi/4 = 3\pi/2$ and $\sin(\omega t + \pi/4) = -1$. Thus

$$\begin{aligned} q_{a,\text{max}}'' &= k\Delta T\sqrt{\omega/\alpha} \\ &= 2.15 \text{ W/m} \cdot \text{K} \times 2 \text{ K} \times \sqrt{7.27 \times 10^{-5} \text{ s}^{-1} / 1.14 \times 10^{-6} \text{ m}^2/\text{s}} \\ &= 34.3 \text{ W/m}^2 \quad < \end{aligned}$$

at $t_o = (3\pi/2 - \pi/4)/\omega = 5.4 \times 10^4 \text{ s}$. Evaluating T_{in} at this time from Equation (2) yields

$$\begin{aligned} T_{\text{in}} &= T_i + \Delta T \sin(\omega t_o) + (k\Delta T\sqrt{\omega/\alpha}/h) \sin(\omega t_o + \pi/4) \\ &= 300 \text{ K} + 2 \text{ K} \sin(7.27 \times 10^{-5} \text{ s}^{-1} \times 5.4 \times 10^4 \text{ s}) \\ &\quad + (2.15 \text{ W/m} \cdot \text{K} \times 2 \text{ K} \times \sqrt{7.27 \times 10^{-5} \text{ s}^{-1} / 1.14 \times 10^{-6} \text{ m}^2/\text{s}} / 10 \text{ W/m}^2 \cdot \text{K}) \times (-1) \\ &= 295 \text{ K} = 22^\circ\text{C} \quad < \end{aligned}$$

An energy balance on the entire volume of air in the fissure yields (see Equation 1.11e)

$$q = \dot{m}c_p(T_{\text{out}} - T_{\text{in}})$$

where $q = 2q_a''Lw$. Thus

$$\begin{aligned} T_{\text{out}} &= T_{\text{in}} + 2q_a''Lw/\rho Vdw c_p \quad (4) \\ &= 22^\circ\text{C} + 2 \times 34.3 \text{ W/m}^2 \times 5 \text{ m} / (1.1614 \text{ kg/m}^3 \times 2 \text{ m/s} \times 0.03 \text{ m} \times 1007 \text{ J/kg} \cdot \text{K}) \\ &= 27^\circ\text{C} \quad < \end{aligned}$$

(c) To find the outlet temperatures we can use Equation (4), but we need to know q_a'' from Equation (3). At the two times noted in part (a),

$$q_a'' = -32.9 \text{ W/m}^2 \quad \text{at} \quad t = 1.5 \times 10^4 \text{ s}$$

$$q_a'' = 32.9 \text{ W/m}^2 \quad \text{at} \quad t = 5.8 \times 10^4 \text{ s}$$

Thus from Equation (4)

$$T_{\text{out}} = 27.4^\circ\text{C} \quad \text{at} \quad t = 1.5 \times 10^4 \text{ s} \quad <$$

$$T_{\text{out}} = 26.6^\circ\text{C} \quad \text{at} \quad t = 5.8 \times 10^4 \text{ s} \quad <$$

(d) The inlet temperature is given by Equation (2). The surface temperature is given as $T_s = T_i + \Delta T \sin \omega t$, and the heat flux to the limestone is given by Equation (1). Plots of these three quantities are given on the next page.

Continued...

PROBLEM 5.90 (Cont.)

(e) The penetration depth is $\delta_p = 4\sqrt{\alpha/\omega} = 0.25$ m. Since the limestone is almost certainly substantially thicker than 0.25 m, it can be treated as semi-infinite.

COMMENTS: In reality, both the air and limestone temperature would vary along the length of the fissure, and conduction would occur in the limestone in the direction parallel to the air flow.

PROBLEM 5.91

KNOWN: Desired minimum temperature response of a 3ω measurement.

FIND: Minimum sample thickness that can be measured.

ASSUMPTIONS: (1) Constant properties, (2) Two-dimensional conduction, (3) Semi-infinite medium, (4) Negligible radiation and convection losses from the metal strip and the top surface of the sample.

PROPERTIES: (Example 5.8): $k = 1.11 \text{ W/m}\cdot\text{K}$, $\alpha = 4.37 \times 10^{-7} \text{ m}^2/\text{s}$.

ANALYSIS: Equation 5.71 maybe rearranged to yield

$$\omega = 2 \exp \left[2 \left(C_2 - \frac{\Delta T L \pi k}{\Delta q_s} \right) \right]$$
$$\omega = 2 \times \exp \left[2 \left(5.35 - \frac{0.1^\circ\text{C} \times 3.5 \times 10^{-3} \text{ m} \times \pi \times 1.11 \text{ W/m}\cdot\text{K}}{3.5 \times 10^{-3} \text{ W}} \right) \right]$$
$$\omega = 44.2 \times 10^3 \text{ rad/s}$$
$$\alpha = 4.37 \times 10^{-7} \text{ m}^2/\text{s}$$

Therefore

$$\delta_p = \sqrt{\alpha/\omega} = \sqrt{4.37 \times 10^{-7} \text{ m}^2/\text{s} / 44.2 \times 10^3 \text{ rad/s}} = 3.1 \times 10^{-6} \text{ m} = 3.1 \text{ }\mu\text{m}$$

The minimum sample thickness is therefore $3.1 \text{ }\mu\text{m}$.

<

COMMENTS: (1) To ensure the thickness of the sample is adequate, the actual minimum thickness should be greater than the thermal penetration depth. (2) The sample thickness could be increased further by increasing the amplitude of the heating rate, Δq_s . (3) It is commonly desired to measure very thin samples to discern the effect of the top and bottom boundaries of a *thin film* on the conduction heat transfer rate, as depicted in Figure 2.6. As the film becomes thinner, the experimental uncertainties increase.

PROBLEM 5.92

KNOWN: Stability criterion for the explicit method requires that the coefficient of the T_m^p term of the one-dimensional, finite-difference equation be zero or positive.

FIND: For $Fo > 1/2$, the finite-difference equation will predict values of T_m^{p+1} which violate the Second law of thermodynamics. Consider the prescribed numerical values.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x , (2) Constant properties, (3) No internal heat generation.

ANALYSIS: The explicit form of the finite-difference equation, Eq. 5.78, for an interior node is

$$T_m^{p+1} = Fo(T_{m+1}^p + T_{m-1}^p) + (1 - 2Fo)T_m^p.$$

The stability criterion requires that the coefficient of T_m^p be zero or greater. That is,

$$(1 - 2Fo) \geq 0 \quad \text{or} \quad Fo \leq \frac{1}{2}.$$

For the prescribed temperatures, consider situations for which $Fo = 1$, $1/2$ and $1/4$ and calculate T_m^{p+1} .

$$\begin{aligned} Fo = 1 \quad T_m^{p+1} &= 1(100 + 100)^\circ\text{C} + (1 - 2 \times 1)50^\circ\text{C} = 250^\circ\text{C} \\ Fo = 1/2 \quad T_m^{p+1} &= 1/2(100 + 100)^\circ\text{C} + (1 - 2 \times 1/2)50^\circ\text{C} = 100^\circ\text{C} \\ Fo = 1/4 \quad T_m^{p+1} &= 1/4(100 + 100)^\circ\text{C} + (1 - 2 \times 1/4)50^\circ\text{C} = 75^\circ\text{C}. \end{aligned}$$

Plotting these distributions above, note that when $Fo = 1$, T_m^{p+1} is greater than 100°C , while for $Fo = 1/2$ and $1/4$, $T_m^{p+1} \leq 100^\circ\text{C}$. The distribution for $Fo = 1$ is thermodynamically impossible: heat is flowing into the node during the time period Δt , causing its temperature to rise; yet heat is flowing in the direction of increasing temperature. This is a violation of the Second law. When $Fo = 1/2$ or $1/4$, the node temperature increases during Δt , but the temperature gradients for heat flow are proper. This will be the case when $Fo \leq 1/2$, verifying the stability criterion.

PROBLEM 5.93

KNOWN: Thin rod of diameter D , initially in equilibrium with its surroundings, T_{sur} , suddenly passes a current I ; rod is in vacuum enclosure and has prescribed electrical resistivity, ρ_e , and other thermophysical properties.

FIND: Transient, finite-difference equation for node m .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in rod, (2) Surroundings are much larger than rod, (3) Properties are constant and evaluated at an average temperature, (4) No convection within vacuum enclosure.

ANALYSIS: The finite-difference equation is derived from the energy conservation requirement on the control volume,

$A_c \Delta x$, where $A_c = \pi D^2 / 4$ and $P = \pi D$.

The energy balance has the form

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = \dot{E}_{\text{st}} \quad q_a + q_b - q_{\text{rad}} + I^2 R_e = \rho c V \frac{T_m^{p+1} - T_m^p}{\Delta t}$$

where $\dot{E}_g = I^2 R_e$ and $R_e = \rho_e \Delta x / A_c$. Using Fourier's law to express the conduction terms, q_a and q_b , and Eq. 1.7 for the radiation exchange term, q_{rad} , find

$$k A_c \frac{T_{m-1}^p - T_m^p}{\Delta x} + k A_c \frac{T_{m+1}^p - T_m^p}{\Delta x} - \varepsilon P \Delta x \sigma (T_m^{4,p} - T_{\text{sur}}^4) + I^2 \frac{\rho_e \Delta x}{A_c} = \rho c A_c \Delta x \frac{T_m^{p+1} - T_m^p}{\Delta t}$$

Divide each term by $\rho c A_c \Delta x / \Delta t$, solve for T_m^{p+1} and regroup to obtain

$$T_m^{p+1} = \frac{k}{\rho c} \cdot \frac{\Delta t}{\Delta x^2} (T_{m-1}^p + T_{m+1}^p) - \left[2 \cdot \frac{k}{\rho c} \cdot \frac{\Delta t}{\Delta x^2} - 1 \right] T_m^p - \frac{\varepsilon P \sigma}{A_c} \cdot \frac{\Delta t}{\rho c} (T_m^{4,p} - T_{\text{sur}}^4) + \frac{I^2 \rho_e}{A_c^2} \cdot \frac{\Delta t}{\rho c}$$

Recognizing that $\text{Fo} = \alpha \Delta t / \Delta x^2$, regroup to obtain

$$T_m^{p+1} = \text{Fo} (T_{m-1}^p + T_{m+1}^p) + (1 - 2 \text{Fo}) T_m^p - \frac{\varepsilon P \sigma \Delta x^2}{k A_c} \cdot \text{Fo} (T_m^{4,p} - T_{\text{sur}}^4) + \frac{I^2 \rho_e \Delta x^2}{k A_c^2} \cdot \text{Fo}$$

The stability criterion is based upon the coefficient of the T_m^p term written as

$$\text{Fo} \leq 1/2$$

<

COMMENTS: Note that we have used the forward-difference representation for the time derivative; see Section 5.10.1. This permits convenient treatment of the non-linear radiation exchange term.

PROBLEM 5.94

KNOWN: One-dimensional wall suddenly subjected to uniform volumetric heating and convective surface conditions.

FIND: Finite-difference equation for node at the surface, $x = -L$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties, (3) Uniform \dot{q} .

ANALYSIS: There are two types of finite-difference equations for the *explicit* and *implicit* methods of solution. Using the energy balance approach, both types will be derived.

Explicit Method. Perform an energy balance on the surface node shown above,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = \dot{E}_{\text{st}} \quad q_{\text{conv}} + q_{\text{cond}} + \dot{q}V = \rho cV \frac{T_0^{p+1} - T_0^p}{\Delta t} \quad (1)$$

$$h(1 \cdot 1)(T_\infty - T_0^p) + k(1 \cdot 1) \frac{T_1^p - T_0^p}{\Delta x} + \dot{q} \left[1 \cdot 1 \cdot \frac{\Delta x}{2} \right] = \rho c \left[1 \cdot 1 \cdot \frac{\Delta x}{2} \right] \frac{T_0^{p+1} - T_0^p}{\Delta t}. \quad (2)$$

For the explicit method, the temperatures on the LHS are evaluated at the *previous* time (p). The RHS provides a *forward*-difference approximation to the time derivative. Divide Eq. (2) by $\rho c \Delta x / 2 \Delta t$ and solve for T_0^{p+1} .

$$T_0^{p+1} = 2 \frac{h \Delta t}{\rho c \Delta x} (T_\infty - T_0^p) + 2 \frac{k \Delta t}{\rho c \Delta x^2} (T_1^p - T_0^p) + \dot{q} \frac{\Delta t}{\rho c} + T_0^p.$$

Introducing the Fourier and Biot numbers,

$$\text{Fo} \equiv (k / \rho c) \Delta t / \Delta x^2 \quad \text{Bi} \equiv h \Delta x / k$$

$$T_0^{p+1} = 2 \text{Fo} \left[T_1^p + \text{Bi} \cdot T_\infty + \frac{\dot{q} \Delta x^2}{2k} \right] + (1 - 2 \text{Fo} - 2 \text{Fo} \cdot \text{Bi}) T_0^p. \quad (3)$$

The stability criterion requires that the coefficient of T_0^p be positive. That is,

$$(1 - 2 \text{Fo} - 2 \text{Fo} \cdot \text{Bi}) \geq 0 \quad \text{or} \quad \text{Fo} \leq 1/2(1 + \text{Bi}). \quad (4) <$$

Implicit Method. Begin as above with an energy balance. In Eq. (2), however, the temperatures on the LHS are evaluated at the *new* (p+1) time. The RHS provides a *backward*-difference approximation to the time derivative.

$$h(T_\infty - T_0^{p+1}) + k \frac{T_1^{p+1} - T_0^{p+1}}{\Delta x} + \dot{q} \left[\frac{\Delta x}{2} \right] = \rho c \left[\frac{\Delta x}{2} \right] \frac{T_0^{p+1} - T_0^p}{\Delta t} \quad (5)$$

$$(1 + 2 \text{Fo}(\text{Bi} + 1)) T_0^{p+1} - 2 \text{Fo} \cdot T_1^{p+1} = T_0^p + 2 \text{Bi} \cdot \text{Fo} \cdot T_\infty + \text{Fo} \frac{\dot{q} \Delta x^2}{k}. \quad (6) <$$

COMMENTS: Compare these results (Eqs. 3, 4 and 6) with the appropriate expression in Table 5.3.

PROBLEM 5.95

KNOWN: Plane wall, initially having a linear, steady-state temperature distribution with boundaries maintained at $T(0,t) = T_1$ and $T(L,t) = T_2$, suddenly experiences a uniform volumetric heat generation due to the electrical current. Boundary conditions T_1 and T_2 remain fixed with time.

FIND: (a) On T - x coordinates, sketch the temperature distributions for the following cases: initial conditions ($t \leq 0$), steady-state conditions ($t \rightarrow \infty$) assuming the maximum temperature exceeds T_2 , and two intermediate times; label important features; (b) For the three-nodal network shown, derive the finite-difference equation using either the implicit or explicit method; (c) With a time increment of $\Delta t = 5$ s, obtain values of T_m for the first 45 s of elapsed time; determine the corresponding heat fluxes at the boundaries; and (d) Determine the effect of mesh size by repeating the foregoing analysis using grids of 5 and 11 nodal points.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, transient conduction, (2) Uniform volumetric heat generation for $t \geq 0$, (3) Constant properties.

PROPERTIES: Wall (Given): $\rho = 4000 \text{ kg/m}^3$, $c = 500 \text{ J/kg}\cdot\text{K}$, $k = 10 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) The temperature distribution on T - x coordinates for the requested cases are shown below. Note the following key features: (1) linear initial temperature distribution, (2) non-symmetrical parabolic steady-state temperature distribution, (3) gradient at $x = L$ is first positive, then zero and becomes negative, and (4) gradient at $x = 0$ is always positive.

(b) Performing an energy balance on the control volume about node m above, for unit area, find

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = \dot{E}_{\text{st}}$$

$$k(1) \frac{T_2 - T_m}{\Delta x} + k(1) \frac{T_1 - T_m}{\Delta x} + \dot{q}(1) \Delta x = \rho(1) c \Delta x \frac{T_m^{p+1} - T_m^p}{\Delta t}$$

$$\text{Fo} [T_1 + T_2 - 2T_m] + \frac{\dot{q} \Delta t}{\rho c_p} = T_m^{p+1} - T_m^p$$

For the T_m term in brackets, use “p” for explicit and “p+1” for implicit form,

Explicit: $T_m^{p+1} = \text{Fo} (T_1^p + T_2^p) + (1 - 2\text{Fo}) T_m^p + \dot{q} \Delta t / c_p$ (1) <

Implicit: $T_m^{p+1} = \left[\text{Fo} (T_1^{p+1} + T_2^{p+1}) + \dot{q} \Delta t / \rho c_p + T_m^p \right] / (1 + 2\text{Fo})$ (2) <

Continued...

PROBLEM 5.95 (Cont.)

(c) With a time increment $\Delta t = 5\text{ s}$, the FDEs, Eqs. (1) and (2) become

$$\text{Explicit: } T_m^{p+1} = 0.5T_m^p + 75 \quad (3)$$

$$\text{Implicit: } T_m^{p+1} = \left(T_m^p + 75 \right) / 1.5 \quad (4)$$

where

$$Fo = \frac{k\Delta t}{\rho c \Delta x^2} = \frac{10 \text{ W/m} \cdot \text{K} \times 5 \text{ s}}{4000 \text{ kg/m}^3 \times 500 \text{ J/kg} \cdot \text{K} (0.010 \text{ m})^2} = 0.25$$

$$\frac{\dot{q}\Delta t}{\rho c} = \frac{2 \times 10^7 \text{ W/m}^3 \times 5 \text{ s}}{4000 \text{ kg/m}^3 \times 500 \text{ J/kg} \cdot \text{K}} = 50 \text{ K}$$

Performing the calculations, the results are tabulated as a function of time,

p	t (s)	T_1 (°C)	T_m (°C)		T_2 (°C)
			Explicit	Implicit	
0	0	0	50	50	100
1	5	0	100.00	83.33	100
2	10	0	125.00	105.55	100
3	15	0	137.50	120.37	100
4	20	0	143.75	130.25	100
5	25	0	146.88	136.83	100
6	30	0	148.44	141.22	100
7	35	0	149.22	144.15	100
8	40	0	149.61	146.10	100
9	45	0	149.80	147.40	100

<

The heat flux at the boundaries at $t = 45\text{ s}$ follows from the energy balances on control volumes about the boundary nodes, using the explicit results for T_m^p ,

$$\text{Node 1: } \dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = \dot{E}_{\text{st}}$$

$$q_x''(0, t) + k \frac{T_m^p - T_1}{\Delta x} + \dot{q}(\Delta x/2) = 0$$

$$q_x''(0, t) = -k \left(T_m^p - T_1 \right) / \Delta x - \dot{q}\Delta x/2 \quad (5)$$

$$q_x''(0, 45\text{ s}) = -10 \text{ W/m} \cdot \text{K} (149.8 - 0) \text{ K} / 0.010 \text{ m} - 2 \times 10^7 \text{ W/m}^3 \times 0.010 \text{ m} / 2$$

$$q_x''(0, 45\text{ s}) = -149,800 \text{ W/m}^2 - 100,000 \text{ W/m}^2 = -249,800 \text{ W/m}^2$$

<

$$\text{Node 2: } k \frac{T_m^p - T_2}{\Delta x} - q_x''(L, t) + \dot{q}(\Delta x/2) = 0$$

$$q_x''(L, t) = k \left(T_m^p - T_2 \right) / \Delta x + \dot{q}\Delta x/2 = 0 \quad (6)$$

Continued...

PROBLEM 5.95 (Cont.)

$$q_x''(L, t) = 10 \text{ W/m} \cdot \text{K} (149.80 - 100) \text{C} / 0.010 \text{ m} + 2 \times 10^7 \text{ W/m}^3 \times 0.010 \text{ m} / 2$$

$$q_x''(L, t) = 49,800 \text{ W/m}^2 + 100,000 \text{ W/m}^2 = +149,800 \text{ W/m}^2 \quad <$$

(d) To determine the effect of mesh size, the above analysis was repeated using grids of 5 and 11 nodal points, $\Delta x = 5$ and 2 mm, respectively. Using the *IHT Finite-Difference Equation Tool*, the finite-difference equations were obtained and solved for the temperature-time history. Eqs. (5) and (6) were used for the heat flux calculations. The results are tabulated below for $t = 45\text{s}$, where $T_m^p(45\text{s})$ is the center node,

Mesh Size Δx (mm)	$T_m^p(45\text{s})$ (°C)	$q_x''(0, 45\text{s})$ kW/m ²	$q_x''(L, 45\text{s})$ kW/m ²
10	149.8	-249.8	+149.8
5	149.3	-249.0	+149.0
2	149.4	-249.1	+149.0

COMMENTS: (1) The center temperature and boundary heat fluxes are quite insensitive to mesh size for the condition.

(2) The copy of the IHT workspace for the 5 node grid is shown below.

```
// Mesh size - 5 nodes, deltax = 5 mm
// Nodes a, b(m), and c are interior nodes

// Finite-Difference Equations Tool - nodal

PROBLEM 5.96

KNOWN: Solid cylinder of plastic material ($\alpha = 6 \times 10^{-7} \text{ m}^2/\text{s}$), initially at uniform temperature of $T_i = 20^\circ\text{C}$, insulated at one end (T_4), while other end experiences heating causing its temperature T_0 to increase linearly with time at a rate of $a = 1^\circ\text{C/s}$.

FIND: (a) Finite-difference equations for the 4 nodes using the explicit method with $Fo = 1/2$ and (b) Surface temperature T_0 when $T_4 = 35^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in cylinder, (2) Constant properties, and (3) Lateral and end surfaces perfectly insulated.

ANALYSIS: (a) The finite-difference equations using the *explicit* method for the interior nodes ($m = 1, 2, 3$) follow from Eq. 5.78 with $Fo = 1/2$,

$$T_m^{p+1} = Fo \left(T_{m+1}^p + T_{m-1}^p \right) + (1 - 2Fo) T_m^p = 0.5 \left(T_{m+1}^p + T_{m-1}^p \right) \quad (1)$$

From an energy balance on the control volume node 4 as shown above yields with $Fo = 1/2$

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st} \quad q_a + q_b + 0 = \rho c V \left(T_4^{p+1} - T_4^p \right) / \Delta t$$

$$0 + k \left(T_3^p - T_4^p \right) / \Delta x = \rho c \left(\Delta x / 2 \right) \left(T_4^{p+1} - T_4^p \right) / \Delta t$$

$$T_4^{p+1} = 2Fo T_3^p + (1 - 2Fo) T_4^p = T_3^p \quad (2)$$

(b) Performing the calculations, the temperature-time history is tabulated below, where $T_0 = T_i + a \cdot t$ where $a = 1^\circ\text{C/s}$ and $t = p \cdot \Delta t$ with,

$$Fo = \alpha \Delta t / \Delta x^2 = 0.5 \quad \Delta t = 0.5 (0.006 \text{ m})^2 / 6 \times 10^{-7} \text{ m}^2/\text{s} = 30 \text{ s}$$

p	t (s)	T_0 ($^\circ\text{C}$)	T_1 ($^\circ\text{C}$)	T_2 ($^\circ\text{C}$)	T_3 ($^\circ\text{C}$)	T_4 ($^\circ\text{C}$)
0	0	20	20	20	20	20
1	30	50	20	20	20	20
2	60	80	35	20	20	20
3	90	110	50	27.5	20	20
4	120	140	68.75	35	23.75	20
5	150	170	87.5	46.25	27.5	23.75
6	180	200	108.1	57.5	35	27.5
7	210	230	-	-	-	35

When $T_4(210 \text{ s}, p = 7) = 35^\circ\text{C}$, find $T_0(210 \text{ s}) = 230^\circ\text{C}$.

<

PROBLEM 5.97

KNOWN: Three-dimensional, transient conduction.

FIND: Explicit finite difference equation for an interior node, stability criterion.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Equal grid spacing in all three directions, (3) No heat generation.

ANALYSIS: We begin with the three-dimensional form of the transient heat equation, Equation 2.19

$$\frac{1}{\alpha} \frac{\partial T}{\partial t} = \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2}$$

The finite-difference approximation to the time derivative is given by Equation 5.74:

$$\left. \frac{\partial T}{\partial t} \right|_{m,n,q} = \frac{T_{m,n,q}^{p+1} - T_{m,n,q}^p}{\Delta t}$$

The spatial derivatives for the x- and y- directions are given by Equations 4.27 and 4.28, with an extra subscript q. By analogy, the z-direction derivative is approximated as

$$\left. \frac{\partial^2 T}{\partial z^2} \right|_{m,n,q} \approx \frac{T_{m,n,q+1} + T_{m,n,q-1} - 2T_{m,n,q}}{(\Delta z)^2}$$

Evaluating the spatial derivatives at time step p for the explicit method, assuming $\Delta x = \Delta y = \Delta z$, yields

Continued...

PROBLEM 5.97 (Cont.)

$$\frac{1}{\alpha} \frac{T_{m,n,q}^{p+1} - T_{m,n,q}^p}{\Delta t} = \frac{T_{m+1,n,q}^p + T_{m-1,n,q}^p - 2T_{m,n,q}^p}{(\Delta x)^2} \\ + \frac{T_{m,n,q+1}^p + T_{m,n,q-1}^p - 2T_{m,n,q}^p}{(\Delta x)^2} \\ + \frac{T_{m,n,q+1}^p + T_{m,n,q-1}^p - 2T_{m,n,q}^p}{(\Delta x)^2}$$

Solving for the nodal temperature at time step p+1 results in

$$T_{m,n,q}^{p+1} = \text{Fo}(T_{m+1,n,q}^p + T_{m-1,n,q}^p + T_{m,n,q+1}^p + T_{m,n,q-1}^p + T_{m,n,q+1}^p + T_{m,n,q-1}^p) \\ + (1 - 6\text{Fo})T_{m,n,q}^p$$

where $\text{Fo} = \alpha \Delta t / (\Delta x)^2$.

The stability criterion is determined by the requirement that the coefficient of $T_{m,n,q}^p \geq 0$. Thus

$$\text{Fo} \leq 1/6$$

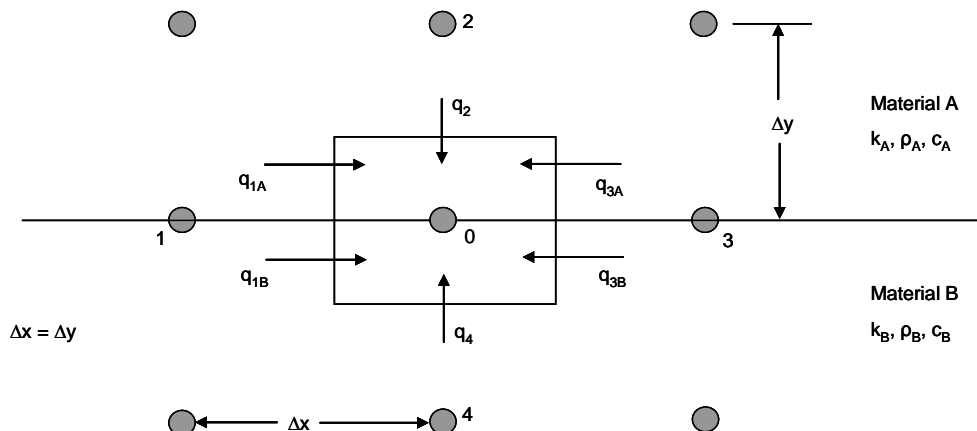

COMMENTS: These results could also have been obtained using the energy balance method applied to a control volume about the interior node.

PROBLEM 5.98

KNOWN: Nodal point located at boundary between two materials A and B.

FIND: Two-dimensional explicit, transient finite difference equation.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) No heat generation, (3) Constant properties (different in each material).

ANALYSIS: We perform an energy balance on the control volume around node 0.

$$\dot{E}_{\text{in}} = \dot{E}_{\text{st}}$$

$$q_{1A} + q_{1B} + q_{3A} + q_{3B} + q_2 + q_4 = \dot{E}_{\text{st},A} + \dot{E}_{\text{st},B}$$

Using q_{1A} as an example,

$$q_{1A} = k_A \frac{T_1 - T_0}{\Delta x} \frac{\Delta y}{2} w = k_A (T_1 - T_0) w / 2$$

where w is the depth into the page. The quantities q_{1B} , q_{3A} , and q_{3B} can be found similarly. Then q_2 is given by

$$q_2 = k_A \frac{T_2 - T_0}{\Delta y} \Delta x w = k_A (T_2 - T_0) w$$

and similarly for q_4 .

The storage term $\dot{E}_{\text{st},A}$ is given by

$$\dot{E}_{\text{st},A} = \rho_A c_A \Delta x \frac{\Delta y}{2} \frac{T_0^{p+1} - T_0^p}{\Delta t}$$

and similarly for $\dot{E}_{\text{st},B}$.

Putting all the terms together yields

Continued....

PROBLEM 5.98 (Cont.)

$$k_A \frac{T_1 - T_0}{2} + k_B \frac{T_1 - T_0}{2} + k_A \frac{T_3 - T_0}{2} + k_B \frac{T_3 - T_0}{2} +$$

$$k_A (T_2 - T_0) + k_B (T_4 - T_0) = (\rho_A c_A + \rho_B c_B) \frac{(\Delta x)^2}{2} \frac{T_0^{p+1} - T_0^p}{\Delta t}$$

Rearranging, we find

$$T_0^{p+1} = \frac{(Fo_A + Fo_B)}{2} (T_1^p + T_3^p) + Fo_A T_2^p + Fo_B T_4^p + [1 - 2(Fo_A + Fo_B)] T_0^p \quad <$$

where

$$Fo_A = \frac{2k_A \Delta t}{(\rho_A c_A + \rho_B c_B)(\Delta x)^2}, \quad Fo_B = \frac{2k_B \Delta t}{(\rho_A c_A + \rho_B c_B)(\Delta x)^2}$$

Note, that $Fo_A \neq \alpha_A \Delta t / (\Delta x)^2$.

COMMENTS: Note that when the material properties are the same for materials A and B, the result agrees with Equation 5.76.

PROBLEM 5.99

KNOWN: A 0.12 m thick wall, with thermal diffusivity $1.5 \times 10^{-6} \text{ m}^2/\text{s}$, initially at a uniform temperature of 85°C , has one face suddenly lowered to 20°C while the other face is perfectly insulated.

FIND: (a) Using the explicit finite-difference method with space and time increments of $\Delta x = 30 \text{ mm}$ and $\Delta t = 300 \text{ s}$, determine the temperature distribution within the wall 45 min after the change in surface temperature; (b) Effect of Δt on temperature histories of the surfaces and midplane.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties.

ANALYSIS: (a) The finite-difference equations for the interior points, nodes 0, 1, 2, and 3, can be determined from Equation 5.78,

$$T_m^{p+1} = \text{Fo} \left(T_{m-1}^p + T_{m+1}^p \right) + (1 - 2\text{Fo}) T_m^p \quad (1)$$

with

$$\text{Fo} = \alpha \Delta t / \Delta x^2 = 1.5 \times 10^{-6} \text{ m}^2/\text{s} \times 300 \text{ s} / (0.03 \text{ m})^2 = 1/2. \quad (2)$$

Note that the stability criterion, Equation 5.79, $\text{Fo} \leq 1/2$, is satisfied. Hence, combining Equations (1) and (2), $T_m^{p+1} = 1/2 \left(T_{m-1}^p + T_{m+1}^p \right)$ for $m = 0, 1, 2, 3$. Since the adiabatic plane at $x = 0$ can be treated as a symmetry plane, $T_{m-1} = T_{m+1}$ for node 0 ($m = 0$). The finite-difference solution is generated in the table below using $t = p \cdot \Delta t = 300 p \text{ (s)} = 5 p \text{ (min)}$.

p	t(min)	T_0	T_1	T_2	T_3	$T_L(^{\circ}\text{C})$
0	0	85	85	85	85	20
1		85	85	85	52.5	20
2	10	85	85	68.8	52.5	20
3		85	76.9	68.8	44.4	20
4	20	76.9	76.9	60.7	44.4	20
5		76.9	68.8	60.7	40.4	20
6	30	68.8	68.8	54.6	40.4	20
7		68.8	61.7	54.6	37.3	20
8	40	61.7	61.7	49.5	37.3	20
9	45	61.7	55.6	49.5	34.8	20

<

The temperature distribution can also be determined from the one-term approximation of the exact solution. The insulated surface is equivalent to the midplane of a wall of thickness $2L$. Thus,

$$\text{Fo} = \frac{\alpha t}{L^2} = \frac{1.5 \times 10^{-6} \text{ m}^2/\text{s} \times (45 \times 60) \text{ s}}{(0.12 \text{ m})^2} = 0.28 \quad \text{and} \quad \text{Bi} \rightarrow \infty.$$

Continued...

PROBLEM 5.99 (Cont.)

From Table 5.1, $\zeta_1 = 1.5707$, $C_1 = 1.2733$. Then from Equation 5.41,

$$\theta_0^* = C_1 \exp(-\zeta_1^2 Fo) = 1.2733 \exp(-1.5707^2 \times 0.28) = 0.64 \quad \text{or}$$

$$T_0 = T(0, t) = T_\infty + \theta_0^* (T_i - T_\infty) = 20^\circ\text{C} + 0.64(85 - 20)^\circ\text{C} = 61.5^\circ\text{C}.$$

This value shows excellent agreement with 61.7°C for the finite-difference method.

(b) Using the IHT *Finite-Difference Equation Tool Pad* for *One-Dimensional Transient Conduction*, temperature histories were computed and results are shown for the insulated surface (T0) and the midplane, as well as for the chilled surface (TL).

Apart from small differences during early stages of the transient, there is excellent agreement between results obtained for the two time steps. The temperature decay at the insulated surface must, of course, lag that of the midplane.

PROBLEM 5.100

KNOWN: Thickness, initial temperature and thermophysical properties of molded plastic part. Convection conditions at one surface. Other surface insulated.

FIND: Surface temperatures after one hour of cooling.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in product, (2) Negligible radiation, at cooled surface, (3) Negligible heat transfer at insulated surface, (4) Constant properties.

ANALYSIS: Adopting the implicit scheme, the finite-difference equation for the cooled surface node is given by Eq. (5.93), from which it follows that

$$(1 + 2Fo + 2FoBi)T_{10}^{p+1} - 2FoT_9^{p+1} = 2FoBiT_\infty + T_{10}^p$$

The general form of the finite-difference equation for any interior node (1 to 9) is given by Eq. (5.94),

$$(1 + 2Fo)T_m^{p+1} - Fo(T_{m-1}^{p+1} + T_{m+1}^{p+1}) = T_m^p$$

The finite-difference equation for the insulated surface node may be obtained by applying the symmetry requirement to Eq. (5.94); that is, $T_{m+1}^p = T_{m-1}^p$. Hence,

$$(1 + 2Fo)T_0^{p+1} - 2FoT_1^{p+1} = T_0^p$$

For the prescribed conditions, $Bi = h\Delta x/k = 100 \text{ W/m}^2\cdot\text{K} (0.006\text{m})/0.03 \text{ W/m}\cdot\text{K} = 2$. If the explicit method were used, the most restrictive stability requirement would be given by Eq. (5.84). Hence, for $Fo(1+Bi) \leq 0.5$, $Fo \leq 0.167$. With $Fo = \alpha\Delta t/\Delta x^2$ and $\alpha = k/\rho c = 1.67 \times 10^{-7} \text{ m}^2/\text{s}$, the corresponding restriction on the time increment would be $\Delta t \leq 36\text{s}$. Although no such restriction applies for the implicit method, a value of $\Delta t = 30\text{s}$ is chosen, and the set of 11 finite-difference equations is solved using the *Tools* option designated as *Finite-Difference Equations, One-Dimensional, and Transient* from the IHT Toolpad. At $t = 3600\text{s}$, the solution yields:

$$T_{10}(3600\text{s}) = 24.1^\circ\text{C} \quad T_0(3600\text{s}) = 71.5^\circ\text{C} \quad <$$

COMMENTS: (1) More accurate results may be obtained from the one-term approximation to the exact solution for one-dimensional, transient conduction in a plane wall. With $Bi = hL/k = 20$, Table 5.1 yields $\zeta_1 = 1.496$ rad and $C_1 = 1.2699$. With $Fo = \alpha t/L^2 = 0.167$, Eq. (5.41) then yields $T_0 = T_\infty + (T_i - T_\infty) C_1 \exp(-\zeta_1^2 Fo) = 72.4^\circ\text{C}$, and from Eq. (5.40b), $T_s = T_\infty + (T_i - T_\infty) \cos(\zeta_1) = 24.5^\circ\text{C}$.

Since the finite-difference results do not change with a reduction in the time step ($\Delta t < 30\text{s}$), the difference between the numerical and analytical results is attributed to the use of a coarse grid. To improve the accuracy of the numerical results, a smaller value of Δx should be used.

Continued

PROBLEM 5.100 (Cont.)

(2) Temperature histories for the front and back surface nodes are as shown.

Although the surface temperatures rapidly approaches that of the coolant, there is a significant lag in the thermal response of the back surface. The different responses are attributable to the small value of α and the large value of Bi.

PROBLEM 5.101

KNOWN: Plane wall, initially at a uniform temperature $T_o = 25^\circ\text{C}$, has one surface ($x = L$) suddenly exposed to a convection process with $T_\infty = 50^\circ\text{C}$ and $h = 1000 \text{ W/m}^2\cdot\text{K}$, while the other surface ($x = 0$) is maintained at T_o . Also, the wall suddenly experiences uniform volumetric heating with $\dot{q} = 1 \times 10^7 \text{ W/m}^3$. See also Problem 2.48.

FIND: (a) Using spatial and time increments of $\Delta x = 4 \text{ mm}$ and $\Delta t = 1 \text{ s}$, compute and plot the temperature distributions in the wall for the initial condition, the steady-state condition, and two intermediate times, and (b) On q''_x - t coordinates, plot the heat flux at $x = 0$ and $x = L$. At what elapsed time is there zero heat flux at $x = L$?

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction and (2) Constant properties.

ANALYSIS: (a) Using the *IHT Finite-Difference Equations, One-Dimensional, Transient Tool*, the temperature distributions were obtained and plotted below.

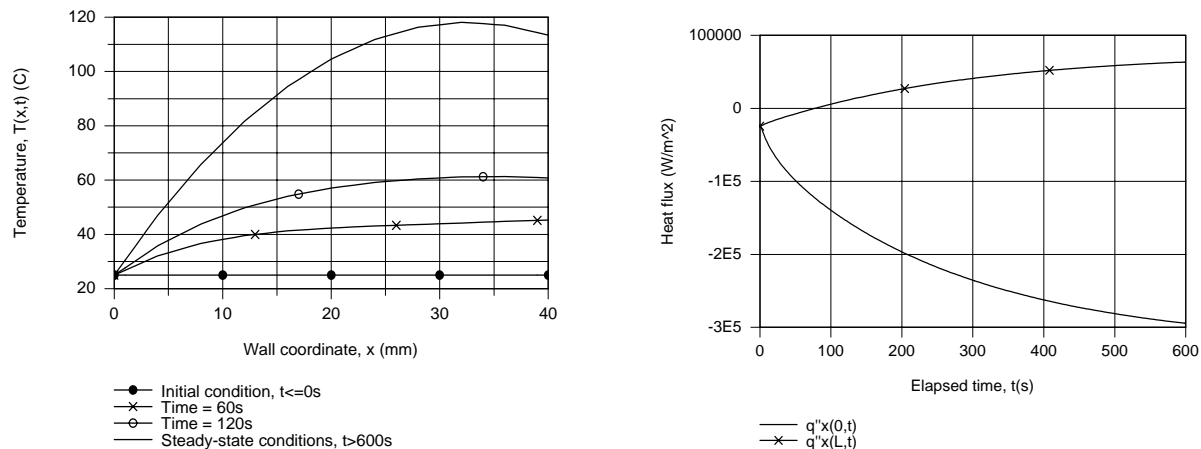

(b) The heat flux, $q''_x(L,t)$, can be expressed in terms of Newton's law of cooling,

$$q''_x(L,t) = h(T_{10}^p - T_\infty).$$

From the energy balance on the control volume about node 0 shown above,

$$q''_x(0,t) + \dot{E}_g + q''_a = 0 \quad q''_x(0,t) = -\dot{q}(\Delta x/2) - k(T_1^p - T_o)/\Delta x$$

From knowledge of the temperature distribution, the heat fluxes are computed and plotted.

COMMENTS: The steady-state analytical solution has the form of Eq. 3.40 where $C_1 = 6500 \text{ m}^{-1}/^\circ\text{C}$ and $C_2 = 25^\circ\text{C}$. Find $q''_x(0,\infty) = -3.25 \times 10^5 \text{ W/m}^2$ and $q''_x(L) = +7.5 \times 10^4 \text{ W/m}^2$. Comparing with the graphical results above, we conclude that steady-state conditions are not reached in 600 s.

PROBLEM 5.102

KNOWN: Fuel element of Example 5.8 is initially at a uniform temperature of 250°C with no internal generation; suddenly a uniform generation, $\dot{q} = 10^8 \text{ W/m}^3$, occurs when the element is inserted into the core while the surfaces experience convection (T_∞, h).

FIND: Temperature distribution 1.5s after element is inserted into the core.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties, (3) $\dot{q} = 0$, initially; at $t > 0$, \dot{q} is uniform.

ANALYSIS: As suggested, the explicit method with a space increment of 2mm will be used. Using the nodal network of Example 5.9, the same finite-difference equations may be used.

Interior nodes, $m = 1, 2, 3, 4$

$$T_m^{p+1} = \text{Fo} \left[T_{m-1}^p + T_{m+1}^p + \frac{\dot{q}(\Delta x)^2}{2} \right] + (1 - 2 \text{Fo}) T_m^p. \quad (1)$$

Midplane node, $m = 0$

Same as Eq. (1), but with $T_{m-1}^p = T_{m+1}^p$.

Surface node, $m = 5$

$$T_5^{p+1} = 2 \text{Fo} \left[T_4^p + \text{Bi} \cdot T_\infty + \frac{\dot{q}(\Delta x)^2}{2k} \right] + (1 - 2\text{Fo} - 2\text{Bi} \cdot \text{Fo}) T_5^p. \quad (2)$$

The most restrictive stability criterion is associated with Eq. (2), $\text{Fo}(1 + \text{Bi}) \leq 1/2$. Consider the following parameters:

$$\begin{aligned} \text{Bi} &= \frac{h\Delta x}{k} = \frac{1100 \text{ W/m}^2 \cdot \text{K} \times (0.002 \text{ m})}{30 \text{ W/m} \cdot \text{K}} = 0.0733 \\ \text{Fo} &\leq \frac{1/2}{(1 + \text{Bi})} = 0.466 \\ \Delta t &\leq \frac{\text{Fo}(\Delta x)^2}{\alpha} = 0.466 \frac{(0.002 \text{ m})^2}{5 \times 10^{-6} \text{ m}^2/\text{s}} = 0.373 \text{ s}. \end{aligned}$$

Continued

PROBLEM 5.102 (Cont.)

To be well within the stability limit, select $\Delta t = 0.3\text{s}$, which corresponds to

$$Fo = \frac{\alpha \Delta t}{\Delta x^2} = \frac{5 \times 10^{-6} \text{ m}^2 / \text{s} \times 0.3 \text{ s}}{(0.002 \text{ m})^2} = 0.375$$

$$t = p \Delta t = 0.3p (\text{s}).$$

Substituting numerical values with $\dot{q} = 10^8 \text{ W/m}^3$, the nodal equations become

$$T_0^{p+1} = 0.375 \left[2T_1^p + 10^8 \text{ W/m}^3 (0.002 \text{ m})^2 / 30 \text{ W/m} \cdot \text{K} \right] + (1 - 2 \times 0.375) T_0^p$$

$$T_0^{p+1} = 0.375 \left[2T_1^p + 13.33 \right] + 0.25 T_0^p \quad (3)$$

$$T_1^{p+1} = 0.375 \left[T_0^p + T_2^p + 13.33 \right] + 0.25 T_1^p \quad (4)$$

$$T_2^{p+1} = 0.375 \left[T_1^p + T_3^p + 13.33 \right] + 0.25 T_2^p \quad (5)$$

$$T_3^{p+1} = 0.375 \left[T_2^p + T_4^p + 13.33 \right] + 0.25 T_3^p \quad (6)$$

$$T_4^{p+1} = 0.375 \left[T_3^p + T_5^p + 13.33 \right] + 0.25 T_4^p \quad (7)$$

$$T_5^{p+1} = 2 \times 0.375 \left[T_4^p + 0.0733 \times 250 + \frac{13.33}{2} \right] + (1 - 2 \times 0.375 - 2 \times 0.0733 \times 0.375) T_5^p$$

$$T_5^{p+1} = 0.750 \left[T_4^p + 24.99 \right] + 0.195 T_5^p. \quad (8)$$

The initial temperature distribution is $T_i = 250^\circ\text{C}$ at all nodes. The marching solution, following the procedure of Example 5.9, is represented in the table below.

p	t(s)	T_0	T_1	T_2	T_3	T_4	$T_5(^{\circ}\text{C})$	
0	0	250	250	250	250	250	250	
1	0.3	255.00	255.00	255.00	255.00	255.00	254.99	
2	0.6	260.00	260.00	260.00	260.00	260.00	259.72	
3	0.9	265.00	265.00	265.00	265.00	264.89	264.39	
4	1.2	270.00	270.00	270.00	269.96	269.74	268.97	
5	1.5	275.00	275.00	274.98	274.89	274.53	273.50	<

The desired temperature distribution $T(x, 1.5\text{s})$, corresponds to $p = 5$.

COMMENTS: Note that the nodes near the midplane (0,1) do not feel any effect of the coolant during the first 1.5s time period.

PROBLEM 5.103

KNOWN: Conditions associated with heat generation in a rectangular fuel element with surface cooling. See Example 5.9.

FIND: (a) The temperature distribution 1.5 s after the change in operating power; compare your results with those tabulated in the example, (b) Calculate and plot temperature histories at the mid-plane (00) and surface (05) nodes for $0 \leq t \leq 400$ s; determine the new steady-state temperatures, and approximately how long it will take to reach the new steady-state condition after the step change in operating power. Use the IHT Tools | *Finite-Difference Equations* | *One-Dimensional* | *Transient* conduction model builder as your solution tool.

SCHEMATIC:

ASSUMPTIONS: (1) One dimensional conduction in the x-direction, (2) Uniform generation, and (3) Constant properties.

ANALYSIS: The IHT model builder provides the transient finite-difference equations for the implicit method of solution. Selected portions of the IHT code used to obtain the results tabulated below are shown in the Comments.

(a) Using the IHT code, the temperature distribution ($^{\circ}\text{C}$) as a function of time (s) up to 1.5 s after the step power change is obtained from the summarized results copied into the workspace

	t	T00	T01	T02	T03	T04	T05
1	0	357.6	356.9	354.9	351.6	346.9	340.9
2	0.3	358.1	357.4	355.4	352.1	347.4	341.4
3	0.6	358.6	357.9	355.9	352.6	347.9	341.9
4	0.9	359.1	358.4	356.4	353.1	348.4	342.3
5	1.2	359.6	358.9	356.9	353.6	348.9	342.8
6	1.5	360.1	359.4	357.4	354.1	349.3	343.2

(b) Using the code, the mid-plane (00) and surface (05) node temperatures are plotted as a function of time.

Continued

PROBLEM 5.103 (Cont.)

Note that at $t \approx 240$ s, the wall has nearly reached the new steady-state condition for which the nodal temperatures ($^{\circ}\text{C}$) were found as:

T00	T01	T02	T03	T04	T05
465	463.7	459.7	453	443.7	431.7

COMMENTS: (1) Can you validate the new steady-state nodal temperatures from part (b) by comparison against an analytical solution?

(2) Will using a smaller time increment improve the accuracy of the results? Use your code with $\Delta t = 0.15$ s to justify your explanation.

(3) Selected portions of the IHT code to obtain the nodal temperature distribution using spatial and time increments of $\Delta x = 2$ mm and $\Delta t = 0.3$ s, respectively, are shown below. For the solve-integration step, the initial condition for each of the nodes corresponds to the steady-state temperature distribution with \dot{q}_1 .

```
// Tools | Finite-Difference Equations | One-Dimensional | Transient
/* Node 00: surface node (w-orientation); transient conditions; e labeled 01. */
rho * cp * der(T00,t) = fd_1d_sur_w(T00,T01,k,qdot,deltax,Tinf01,h01,q'a00)
q'a00 = 0 // Applied heat flux, W/m^2; zero flux shown
Tinf01 = 20 // Arbitrary value

PROBLEM 5.104

KNOWN: Conditions associated with heat generation in a rectangular fuel element with surface cooling. See Example 5.9.

FIND: (a) The temperature distribution 1.5 s after the change in the operating power; compare results with those tabulated in the Example, and (b) Plot the temperature histories at the midplane, $x = 0$, and the surface, $x = L$, for $0 \leq t \leq 400$ s; determine the new steady-state temperatures, and approximately how long it takes to reach this condition. Use the finite-element software *FEHT* as your solution tool.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x -direction, (2) Uniform generation, (3) Constant properties.

ANALYSIS: Using *FEHT*, an outline of the fuel element is drawn of thickness 10 mm in the x -direction and arbitrary length in the y -direction. The boundary conditions are specified as follows: on the y -planes and the $x = 0$ plane, treat as adiabatic; on the $x = 10$ mm plane, specify the convection option. Specify the material properties and the internal generation with \dot{q}_1 . In the *Setup* menu, click on *Steady-state*, and then *Run* to obtain the temperature distribution corresponding to the initial temperature distribution, $T_1(x, 0) = T(x, \dot{q}_1)$, before the change in operating power to \dot{q}_2 .

Next, in the *Setup* menu, click on *Transient*; in the *Specify / Internal Generation* box, change the value to \dot{q}_2 ; and in the *Run* command, click on *Continue* (not *Calculate*).

(a) The temperature distribution 1.5 s after the change in operating power from the *FEHT* analysis and from the *FDE* analysis in the Example are tabulated below.

x/L	0	0.2	0.4	0.6	0.8	1.0
$T(x/L, 1.5 \text{ s})$						
FEHT ($^{\circ}\text{C}$)	360.1	359.4	357.4	354.1	349.3	343.2
FDE ($^{\circ}\text{C}$)	360.08	359.41	357.41	354.07	349.37	343.27

The mesh spacing for the *FEHT* analysis was 0.5 mm and the time increment was 0.005 s. For the *FDE* analyses, the spatial and time increments were 2 mm and 0.3 s. The agreement between the results from the two numerical methods is within 0.1°C .

(b) Using the *FEHT* code, the temperature histories at the mid-plane ($x = 0$) and the surface ($x = L$) are plotted as a function of time.

Continued

PROBLEM 5.104 (Cont.)

From the distribution, the steady-state condition (based upon 98% change) is approached in 215 s. The steady-state temperature distributions after the step change in power from the FEHT and FDE analysis in the Example are tabulated below. The agreement between the results from the two numerical methods is within 0.1°C

x/L	0	0.2	0.4	0.6	0.8	1.0
$T(x/L, \infty)$						
FEHT ($^{\circ}\text{C}$)	465.0	463.7	459.6	453.0	443.6	431.7
FDE ($^{\circ}\text{C}$)	465.15	463.82	459.82	453.15	443.82	431.82

COMMENTS: (1) For background information on the *Continue* option, see the *Run* menu in the *FEHT Help* section. Using the *Run/Calculate* command, the steady-state temperature distribution was determined for the \dot{q}_1 operating power. Using the *Run/Continue* command (after re-setting the generation to \dot{q}_2 and clicking on *Setup / Transient*), this steady-state distribution automatically becomes the initial temperature distribution for the \dot{q}_2 operating power. This feature allows for conveniently prescribing a non-uniform initial temperature distribution for a transient analysis (rather than specifying values on a node-by-node basis).

(2) Use the *View | Tabular Output* command to obtain nodal temperatures to the maximum number of significant figures resulting from the analysis.

(3) Can you validate the new steady-state nodal temperatures from part (b) (with \dot{q}_2 , $t \rightarrow \infty$) by comparison against an analytical solution?

PROBLEM 5.105

KNOWN: Thickness, initial temperature, speed and thermophysical properties of steel in a thin-slab continuous casting process. Surface convection conditions.

FIND: Time required to cool the outer surface to a prescribed temperature. Corresponding value of the midplane temperature and length of cooling section.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible radiation at quenched surfaces, (3) Symmetry about the midplane, (4) Constant properties.

ANALYSIS: Adopting the implicit scheme, the finite-difference equation for the cooled surface node is given by Eq. (5.93), from which it follows that

$$(1 + 2Fo + 2FoBi)T_{10}^{p+1} - 2FoT_9^{p+1} = 2FoBiT_{\infty} + T_{10}^p$$

The general form of the finite-difference equation for any interior node (1 to 9) is given by Eq. (5.94),

$$(1 + 2Fo)T_m^{p+1} - Fo(T_{m-1}^{p+1} + T_{m+1}^{p+1}) = T_m^p$$

The finite-difference equation for the midplane node may be obtained by applying the symmetry requirement to Eq. (5.94); that is, $T_{m+1}^p = T_{m-1}^p$. Hence,

$$(1 + 2Fo)T_0^{p+1} - 2FoT_1^{p+1} = T_0^p$$

For the prescribed conditions, $Bi = h\Delta x/k = 5000 \text{ W/m}^2 \cdot \text{K} (0.010\text{m})/30 \text{ W/m} \cdot \text{K} = 1.67$. If the explicit method were used, the stability requirement would be given by Eq. (5.84). Hence, for $Fo(1 + Bi) \leq 0.5$, $Fo \leq 0.187$. With $Fo = \alpha\Delta t/\Delta x^2$ and $\alpha = k/\rho c = 5.49 \times 10^{-6} \text{ m}^2/\text{s}$, the corresponding restriction on the time increment would be $\Delta t \leq 3.40\text{s}$. Although no such restriction applies for the implicit method, a value of $\Delta t = 1\text{s}$ is chosen, and the set of 11 finite-difference equations is solved using the *Tools* option designated as *Finite-Difference Equations, One-Dimensional* and *Transient* from the IHT Toolpad. For $T_{10}(t) = 300^\circ\text{C}$, the solution yields

$$t = 161\text{s}$$

<

Continued

PROBLEM 5.105 (Cont.)

$$T_0(t) = 1364^\circ\text{C}$$

<

With a casting speed of $V = 15 \text{ mm/s}$, the length of the cooling section is

$$L_{\text{CS}} = Vt = 0.015 \text{ m/s}(161 \text{ s}) = 2.42 \text{ m}$$

<

COMMENTS: (1) With $\text{Fo} = \alpha t/L^2 = 0.088 < 0.2$, the one-term approximation to the exact solution for one-dimensional conduction in a plane wall cannot be used to confirm the foregoing results. However, using the exact solution from the *Models, Transient Conduction, Plane Wall* Option of IHT, values of $T_0 = 1366^\circ\text{C}$ and $T_s = 200.7^\circ\text{C}$ are obtained and are in good agreement with the finite-difference predictions. The accuracy of these predictions could still be improved by reducing the value of Δx .

(2) Temperature histories for the surface and midplane nodes are plotted for $0 < t < 600 \text{ s}$.

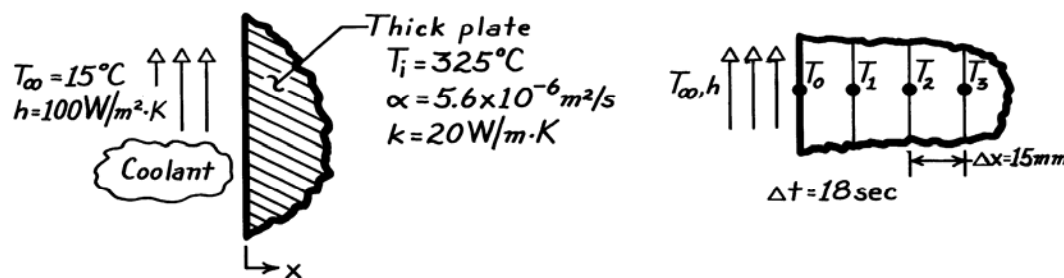

While $T_{10}(600 \text{ s}) = 124^\circ\text{C}$, $T_0(600 \text{ s})$ has only dropped to 879°C . The much slower thermal response at the midplane is attributable to the small value of α and the large value of $\text{Bi} = 16.67$.

PROBLEM 5.106

KNOWN: Very thick plate, initially at a uniform temperature, T_i , is suddenly exposed to a convection cooling process (T_∞, h).

FIND: Temperatures at the surface and a 45mm depth after 3 minutes using finite-difference method with space and time increments of 15mm and 18s.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Plate approximates semi-infinite medium, (3) Constant properties.

ANALYSIS: The grid network representing the plate is shown above. The finite-difference equation for node 0 is given by Eq. 5.87 for one-dimensional conditions or Eq. 5.82,

$$T_0^{p+1} = 2 \text{Fo} (T_1^p + \text{Bi} \cdot T_\infty) + (1 - 2 \text{Fo} - 2 \text{Bi} \cdot \text{Fo}) T_0^p. \quad (1)$$

The numerical values of Fo and Bi are

$$\text{Fo} = \frac{\alpha \Delta t}{\Delta x^2} = \frac{5.6 \times 10^{-6} \text{ m}^2/\text{s} \times 18 \text{ s}}{(0.015 \text{ m})^2} = 0.448$$

$$\text{Bi} = \frac{h \Delta x}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times (15 \times 10^{-3} \text{ m})}{20 \text{ W/m} \cdot \text{K}} = 0.075.$$

Recognizing that $T_\infty = 15^\circ\text{C}$, Eq. (1) has the form

$$T_0^{p+1} = 0.0359 T_0^p + 0.897 T_1^p + 1.01. \quad (2)$$

It is important to satisfy the stability criterion, $\text{Fo} (1 + \text{Bi}) \leq 1/2$. Substituting values, $0.448 (1 + 0.075) = 0.482 \leq 1/2$, and the criterion is satisfied.

The finite-difference equation for the interior nodes, $m = 1, 2, \dots$, follows from Eq. 5.78,

$$T_m^{p+1} = \text{Fo} (T_{m+1}^p + T_{m-1}^p) + (1 - 2\text{Fo}) T_m^p. \quad (3)$$

Recognizing that the stability criterion, $\text{Fo} \leq 1/2$, is satisfied with $\text{Fo} = 0.448$,

$$T_m^{p+1} = 0.448 (T_{m+1}^p + T_{m-1}^p) + 0.104 T_m^p. \quad (4)$$

Continued

PROBLEM 5.106 (Cont.)

The time scale is related to p , the number of steps in the calculation procedure, and Δt , the time increment,

$$t = p\Delta t. \quad (5)$$

The finite-difference calculations can now be performed using Eqs. (2) and (4). The results are tabulated below.

p	$t(s)$	T_0	T_1	T_2	T_3	T_4	T_5	T_6	$T_7(K)$
0	0	325	325	325	325	325	325	325	325
1	18	304.2	324.7	325	325	325	325	325	325
2	36	303.2	315.3	324.5	325	325	325	325	325
3	54	294.7	313.7	320.3	324.5	325	325	325	325
4	72	293.0	307.8	318.9	322.5	324.5	325	325	325
5	90	287.6	305.8	315.2	321.5	323.5	324.5	325	325
6	108	285.6	301.6	313.5	319.3	322.7	324.0	324.5	325
7	126	281.8	299.5	310.5	317.9	321.4	323.3	324.2	
8	144	279.8	296.2	308.6	315.8	320.4	322.5		
9	162	276.7	294.1	306.0	314.3	319.0			
10	180	274.8	291.3	304.1	312.4				

Hence, find

$$T(0, 180s) = T_0^{10} = 275^\circ\text{C} \quad T(45\text{mm}, 180s) = T_3^{10} = 312^\circ\text{C}. \quad <$$

COMMENTS: (1) The above results can be readily checked against the analytical solution represented in Fig. 5.8 (see also Eq. 5.60). For $x = 0$ and $t = 180s$, find

$$\frac{x}{2(\alpha t)^{1/2}} = 0$$

$$\frac{h(\alpha t)^{1/2}}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \left(5.60 \times 10^{-6} \text{ m}^2/\text{s} \times 180s \right)^{1/2}}{20 \text{ W/m} \cdot \text{K}} = 0.16$$

for which the figure gives

$$\frac{T - T_i}{T_\infty - T_i} = 0.15$$

so that,

$$T(0, 180s) = 0.15(T_\infty - T_i) + T_i = 0.15(15 - 325)^\circ\text{C} + 325^\circ\text{C}$$

$$T(0, 180s) = 278^\circ\text{C}.$$

For $x = 45\text{mm}$, the procedure yields $T(45\text{mm}, 180s) = 316^\circ\text{C}$. The agreement with the numerical solution is nearly within 1%.

PROBLEM 5.107

KNOWN: Sudden exposure of the surface of a thick slab, initially at a uniform temperature, to convection and to surroundings at a high temperature.

FIND: (a) Explicit, finite-difference equation for the surface node in terms of Fo , Bi , Bi_r , (b) Stability criterion; whether it is more restrictive than that for an interior node and does it change with time, and (c) Temperature at the surface and at 30mm depth for prescribed conditions after 1 minute exposure.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Thick slab may be approximated as semi-infinite medium, (3) Constant properties, (4) Radiation exchange is between small surface and large surroundings.

ANALYSIS: (a) The explicit form of the FDE for the surface node may be obtained by applying an energy balance to a control volume about the node.

$$\dot{E}_{in}'' - \dot{E}_{out}'' = q_{conv}'' + q_{rad}'' + q_{cond}'' = \dot{E}_{st}''$$

$$h(T_{\infty} - T_0^p) + h_r(T_{sur} - T_0^p) + k \cdot 1 \cdot \frac{T_1^p - T_0^p}{\Delta x}$$

$$= \rho c \left[\frac{\Delta x}{2} \cdot 1 \right] \frac{T_0^{p+1} - T_0^p}{\Delta t} \quad (1)$$

where the radiation process has been linearized, Eq. 1.8. (See also Comment 4, Example 5.10),

$$h_r = h_r^p(T_0^p, T_{sur}) = \epsilon \sigma (T_0^p + T_{sur}) \left([T_0^p]^2 + T_{sur}^2 \right) \quad (2)$$

Divide Eq. (1) by $\rho c \Delta x / 2 \Delta t$ and regroup using these definitions to obtain the FDE:

$$Fo \equiv (k / \rho c) \Delta t / \Delta x^2 \quad Bi \equiv h \Delta x / k \quad Bi_r \equiv h_r \Delta x / k \quad (3,4,5)$$

$$T_0^{p+1} = 2Fo (Bi \cdot T_{\infty} + Bi_r \cdot T_{sur} + T_1^p) + (1 - 2Bi \cdot Fo - 2Bi_r \cdot Fo - 2Fo) T_0^p. \quad (6) <$$

(b) The stability criterion for Eq. (6) requires that the coefficient of T_0^p be positive.

$$1 - 2Fo(Bi + Bi_r + 1) \geq 0 \quad \text{or} \quad Fo \leq 1/2(Bi + Bi_r + 1). \quad (7) <$$

The stability criterion for an interior node, Eq. 5.79, is $Fo \leq 1/2$. Since $Bi + Bi_r > 0$, the stability criterion of the surface node is more restrictive. Note that Bi_r is not constant but depends upon h_r which increases with increasing T_0^p (time). Hence, the restriction on Fo increases with increasing T_0^p (time).

Continued

PROBLEM 5.107 (Cont.)

(c) Consider the prescribed conditions with negligible convection ($Bi = 0$). The FDEs for the thick slab are:

$$\text{Surface } (0) \quad T_0^{p+1} = 2Fo \left(Bi \cdot Fo + Bi_r \cdot T_{sur} + T_1^p \right) + (1 - 2Bi \cdot Fo - 2Bi_r \cdot Fo - 2Fo) T_0^p \quad (8)$$

$$\text{Interior } (m \geq 1) \quad T_m^{p+1} = Fo \left(T_{m+1}^p + T_{m-1}^p \right) + (1 - 2Fo) T_m^p \quad (9,5,7,3)$$

The stability criterion from Eq. (7) with $Bi = 0$ is,

$$Fo \leq 1/2(1 + Bi_r) \quad (10)$$

To proceed with the explicit, marching solution, we need to select a value of Δt (Fo) that will satisfy the stability criterion. A few trial calculations are helpful. A value of $\Delta t = 15s$ provides $Fo = 0.105$, and using Eqs. (2) and (5), $h_r(300K, 1000K) = 72.3 \text{ W/m}^2 \cdot K$ and $Bi_r = 0.482$. From the stability criterion, Eq. (10), find $Fo \leq 0.337$. With increasing T_0^p , h_r and Bi_r increase: $h_r(800K, 1000K) = 150.6 \text{ W/m}^2 \cdot K$, $Bi_r = 1.004$ and $Fo \leq 0.249$. Hence, if $T_0^p < 800K$, $\Delta t = 15s$ or $Fo = 0.105$ satisfies the stability criterion.

Using $\Delta t = 15s$ or $Fo = 0.105$ with the FDEs, Eqs. (8) and (9), the results of the solution are tabulated below. Note how h_r^p and Bi_r^p are evaluated at each time increment. Note that $t = p \cdot \Delta t$, where $\Delta t = 15s$.

p	t(s)	$T_0 / h_r^p / Bi_r$	T1(K)	T2	T3	T4
0	0	300 72.3 0.482	300	300	300	300	
1	15	370.867 79.577 0.5305	300	300	300	300	
2	30	426.079 85.984 0.5733	307.441	300	300	300	
3	45	470.256 91.619 0.6108	319.117	300.781	300	300	
4	60	502.289	333.061	302.624	300.082	300	

After 60s($p = 4$), $T_0(0, 1 \text{ min}) = 502.3K$ and $T_3(30mm, 1 \text{ min}) = 300.1K$. <

COMMENTS: (1) The form of the FDE representing the surface node agrees with Eq. 5.87 if this equation is reduced to one-dimension.

(2) We should recognize that the $\Delta t = 15s$ time increment represents a coarse step. To improve the accuracy of the solution, a smaller Δt should be chosen.

PROBLEM 5.108

KNOWN: Thick slab of copper, initially at a uniform temperature, is suddenly exposed to a constant net radiant flux at one surface. See Example 5.10.

FIND: (a) The nodal temperatures at nodes 00 and 04 at $t = 120$ s; that is, $T_{00}(0, 120 \text{ s})$ and $T_{04}(0.15 \text{ m}, 120 \text{ s})$; compare results with those given by the exact solution in Comment 1; will a time increment of 0.12 s provide more accurate results?; and, (b) Plot the temperature histories for $x = 0, 150$ and 600 mm , and explain key features of your results. Use the *IHT Tools / Finite-Difference Equations / One-Dimensional / Transient* conduction model builder to obtain the implicit form of the FDEs for the interior nodes. Use space and time increments of 37.5 mm and 1.2 s , respectively, for a 17-node network. For the surface node 00, use the FDE derived in Section 2 of the Example.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x -direction, (2) Slab of thickness 600 mm approximates a semi-infinite medium, and (3) Constant properties.

ANALYSIS: The IHT model builder provides the implicit-method FDEs for the interior nodes, 01 – 15. The $+x$ boundary condition for the node-16 control volume is assumed adiabatic. The FDE for the surface node 00 exposed to the net radiant flux was derived in the Example analysis. Selected portions of the IHT code used to obtain the following results are shown in the Comments.

(a) The 00 and 04 nodal temperatures for $t = 120 \text{ s}$ are tabulated below using a time increment of $\Delta t = 1.2 \text{ s}$ and 0.12 s , and compared with the results given from the exact analytical solution, Eq. 5.59.

Node	FDE results ($^{\circ}\text{C}$)		Analytical result ($^{\circ}\text{C}$)
	$\Delta t = 1.2 \text{ s}$	$\Delta t = 0.12 \text{ s}$	
00	119.3	119.4	Eq. 5.59 120.0
04	45.09	45.10	45.4

The numerical FDE-based results with the different time increments agree quite closely with one another. At the surface, the numerical results are nearly 1°C less than the result from the exact analytical solution. This difference represents an error of -1% ($-1^{\circ}\text{C} / (120 - 20)^{\circ}\text{C} \times 100$). At the $x = 150 \text{ mm}$ location, the difference is about -0.4°C , representing an error of -1.5% . For this situation, the smaller time increment (0.12 s) did not provide improved accuracy. To improve the accuracy of the numerical model, it would be necessary to reduce the space increment, in addition to using the smaller time increment.

(b) The temperature histories for $x = 0, 150$ and 600 mm (nodes 00, 04, and 16) for the range $0 \leq t \leq 150 \text{ s}$ are as follows.

Continued

PROBLEM 5.108 (Cont.)

As expected, the surface temperature, $T_{00} = T(0, t)$, increases markedly at early times. As thermal penetration increases with increasing time, the temperature at the location $x = 150$ mm, $T_{04} = T(150 \text{ mm}, t)$, begins to increase after about 20 s. Note, however, the temperature at the location $x = 600$ mm, $T_{16} = T(600 \text{ mm}, t)$, does not change significantly within the 150 s duration of the applied surface heat flux. Our assumption of treating the $+x$ boundary of the node 16 control volume as adiabatic is justified. A copper plate of 600-mm thickness is a good approximation to a semi-infinite medium at times less than 150 s.

COMMENTS: Selected portions of the *IHT* code with the nodal equations to obtain the temperature distribution are shown below. Note how the FDE for node 00 is written in terms of an energy balance using the $der(T, t)$ function. The FDE for node 16 assumes that the “east” boundary is adiabatic.

```
// Finite-difference equation, node 00; from Examples solution derivation; implicit method
q''o + k * (T01 - T00) / deltax = rho * (deltax / 2) * cp * der (T00,t)

// Finite-difference equations, interior nodes 01-15; from Tools
/* Node 01: interior node; e and w labeled 02 and 00. */
rho*cp*der(T01,t) = fd_1d_int(T01,T02,T00,k,qdot,deltax)
rho*cp*der(T02,t) = fd_1d_int(T02,T03,T01,k,qdot,deltax)
.....
rho*cp*der(T14,t) = fd_1d_int(T14,T15,T13,k,qdot,deltax)
rho*cp*der(T15,t) = fd_1d_int(T15,T16,T14,k,qdot,deltax)

// Finite-difference equation node 16; from Tools, adiabatic surface
/* Node 16: surface node (e-orientation); transient conditions; w labeled 15. */
rho * cp * der(T16,t) = fd_1d_sur_e(T16,T15,k,qdot,deltax,Tinf16,h16,q''a16)
q''a16 = 0           // Applied heat flux, W/m^2; zero flux shown
Tinf16 = 20         // Arbitrary value
h16 = 1e-8          // Causes boundary to behave as adiabatic
```

PROBLEM 5.109

KNOWN: Thick slab of copper as treated in Example 5.10, initially at a uniform temperature, is suddenly exposed to large surroundings at 1000°C (instead of a net radiant flux).

FIND: (a) The temperatures $T(0, 120 \text{ s})$ and $T(0.15 \text{ m}, 120 \text{ s})$ using the finite-element software *FEHT* for a surface emissivity of 0.94 and (b) Plot the temperature histories for $x = 0, 150$ and 600 mm , and explain key features of your results.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x -direction, (2) Slab of thickness 600 mm approximates a semi-infinite medium, (3) Slab is small object in large, isothermal surroundings.

ANALYSIS: (a) Using *FEHT*, an outline of the slab is drawn of thickness 600 mm in the x -direction and arbitrary length in the y -direction. Click on *Setup | Temperatures in K*, to enter all temperatures in kelvins. The boundary conditions are specified as follows: on the y -planes and the $x = 600 \text{ mm}$ plane, treat as adiabatic; on the surface $(0, y)$, select the convection coefficient option, enter the linearized radiation coefficient after Eq. 1.9 written as

$$0.94 * 5.67\text{e-}8 * (T + 1273) * (T^2 + 1273^2)$$

and enter the surroundings temperature, 1273 K, in the fluid temperature box. See the Comments for a view of the input screen. From *View/Temperatures*, find the results:

$$T(0, 120 \text{ s}) = 339 \text{ K} = 66^\circ\text{C} \quad T(150 \text{ mm}, 120 \text{ s}) = 305 \text{ K} = 32^\circ\text{C}$$

<

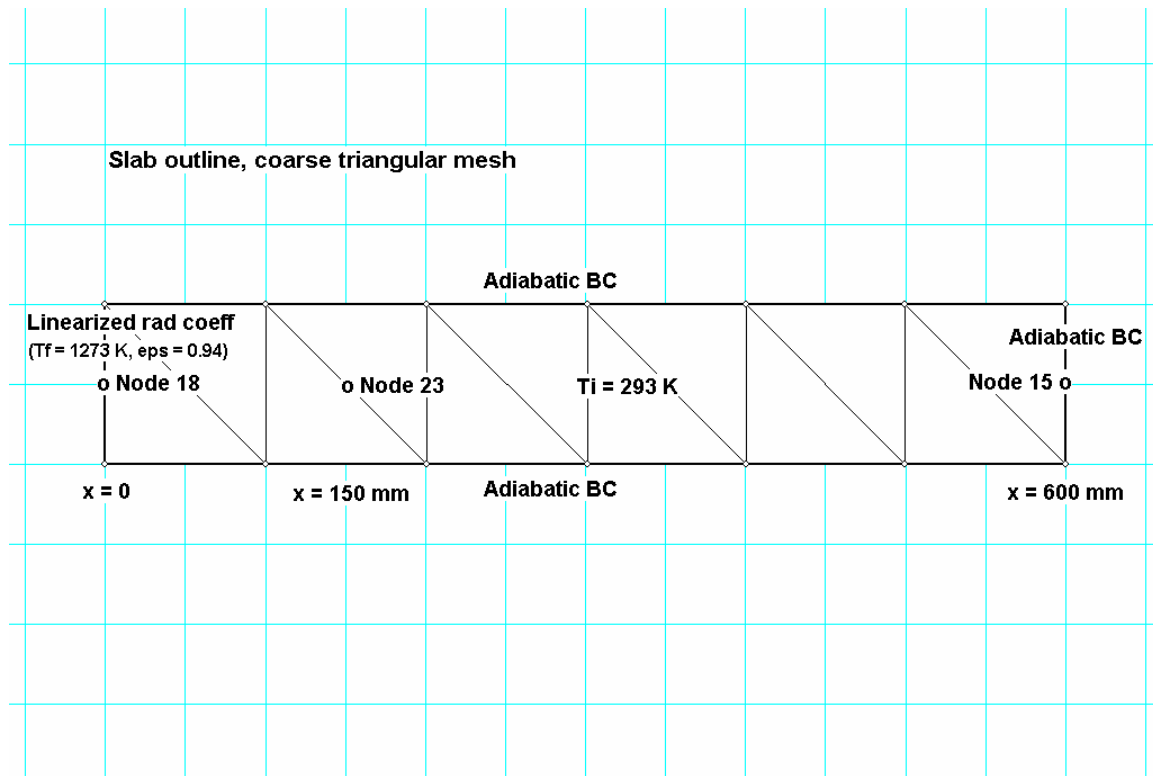

(b) Using the *View / Temperatures* command, the temperature histories for $x = 0, 150$ and 600 mm (10 mm mesh, Nodes 18, 23 and 15, respectively) are plotted. As expected, the surface temperature increases markedly at early times. As thermal penetration increases with increasing time, the temperature at the location $x = 150 \text{ mm}$ begins to increase after about 30 s. Note, however, that the temperature at the location $x = 600 \text{ mm}$ does not change significantly within the 150 s exposure to the hot surroundings. Our assumption of treating the boundary at the $x = 600 \text{ mm}$ plane as adiabatic is justified. A copper plate of 600 mm is a good approximation to a semi-infinite medium at times less than 150 s.

Continued

PROBLEM 5.109 (Cont.)

COMMENTS: The annotated *Input* screen shows the outline of the slab, the boundary conditions, and the triangular mesh before using the *Reduce-mesh* option.

PPROBLEM 5.110

KNOWN: Electric heater sandwiched between two thick plates whose surfaces experience convection. Case 2 corresponds to steady-state operation with a loss of coolant on the $x = -L$ surface. Suddenly, a second loss of coolant condition occurs on the $x = +L$ surface, but the heater remains energized for the next 15 minutes. Case 3 corresponds to the eventual steady-state condition following the second loss of coolant event. See Problem 2.53.

FIND: Calculate and plot the temperature time histories at the plate locations $x = 0, \pm L$ during the transient period between steady-state distributions for Case 2 and Case 3 using the finite-element approach with *FEHT* and the finite-difference method of solution with *IHT* ($\Delta x = 5$ mm and $\Delta t = 1$ s).

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Heater has negligible thickness, and (4) Negligible thermal resistance between the heater surfaces and the plates.

PROPERTIES: Plate material (*given*); $\rho = 2500 \text{ kg/m}^3$, $c = 700 \text{ J/kg}\cdot\text{K}$, $k = 5 \text{ W/m}\cdot\text{K}$.

ANALYSIS: The temperature distribution for Case 2 shown in the above graph represents the initial condition for the period of time following the second loss of coolant event. The boundary conditions at $x = \pm L$ are adiabatic, and the heater flux is maintained at $\dot{q}''_0 = 4000 \text{ W/m}^2$ for $0 \leq t \leq 15$ min.

Using *FEHT*, the heater is represented as a plate of thickness $L_h = 0.5$ mm with very low thermal capacitance ($\rho = 1 \text{ kg/m}^3$ and $c = 1 \text{ J/kg}\cdot\text{K}$), very high thermal conductivity ($k = 10,000 \text{ W/m}\cdot\text{K}$), and a uniform volumetric generation rate of $\dot{q} = \dot{q}''_0 / L_h = 4000 \text{ W/m}^2 / 0.0005 \text{ m} = 8.0 \times 10^6 \text{ W/m}^3$ for $0 \leq t \leq 900$ s. In the *Specify | Generation* box, the generation was prescribed by the *lookup file* (see *FEHT* Help): 'hfvst', 1, 2, Time. This *Notepad* file is comprised of four lines, with the values on each line separated by a single tab space:

```
0      8e6
900    8e6
901    0
5000   0
```

The temperature-time histories are shown in the graph below for the surfaces $x = -L$ (lowest curve, 13) and $x = +L$ (19) and the center point $x = 0$ (highest curve, 14). The center point experiences the maximum temperature of 89°C at the time the heater is deactivated, $t = 900$ s.

Continued

PROBLEM 5.110 (Cont.)

For the finite-difference method of solution, the nodal arrangement for the system is shown below. The *IHT* model builder *Tools* | *Finite-Difference Equations* | *One Dimensional* can be used to obtain the FDEs for the internal nodes (02-04, 07-10) and the adiabatic boundary nodes (01, 11).

For the heater-plate interface node 06, the FDE for the implicit method is derived from an energy balance on the control volume shown in the schematic above.

$$\begin{aligned}\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' + \dot{E}_{\text{gen}}'' &= \dot{E}_{\text{st}}'' \\ q_a'' + q_b'' + q_o'' &= \dot{E}_{\text{st}}'' \\ k \frac{T_{05}^{p+1} - T_{06}^{p+1}}{\Delta x} + k \frac{T_{07}^{p+1} - T_{06}^{p+1}}{\Delta x} + q_o'' &= \rho c \Delta x \frac{T_{06}^{p+1} - T_{06}^p}{\Delta t}\end{aligned}$$

The *IHT* code representing selected nodes is shown below for the adiabatic boundary node 01, interior node 02, and the heater-plates interface node 06. Note how the foregoing derived finite-difference equation in implicit form is written in the *IHT Workspace*. Note also the use of a *Lookup Table* for representing the heater flux vs. time.

    5000   0      */
```

The temperature-time histories using the *IHT* code for the plate locations $x = 0, \pm L$ are shown in the graphs below. We chose to show expanded presentations of the histories at early times, just after the second loss of coolant event, $t = 0$, and around the time the heater is deactivated, $t = 900$ s.

COMMENTS: (1) The maximum temperature during the transient period is at the center point and occurs at the instant the heater is deactivated, $T(0, 900\text{s}) = 89^\circ\text{C}$. After 300 s, note that the two surface temperatures are nearly the same, and never rise above the final steady-state temperature.

(2) Both the FEHT and IHT methods of solution give identical results. Their steady-state solutions agree with the result of an energy balance on a time interval basis yielding $T_{ss} = 86.1^\circ\text{C}$.

PROBLEM 5.111

KNOWN: Plane wall of thickness $2L$, initially at a uniform temperature, is suddenly subjected to convection heat transfer.

FIND: The mid-plane, $T(0,t)$, and surface, $T(L,t)$, temperatures at $t = 50, 100, 200$ and 500 s, using the following methods: (a) the one-term series solution; determine also the Biot number; (b) the lumped capacitance solution; and (c) the two- and 5-node finite-difference numerical solutions. Prepare a table summarizing the results and comment on the relative differences of the predicted temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x -direction, and (2) Constant properties.

ANALYSIS: (a) The results are tabulated below for the mid-plane and surface temperatures using the one-term approximation to the series solution, Eq. 5.40 and 5.41. The Biot number for the heat transfer process is

$$Bi = hL/k = 500 \text{ W/m}^2 \cdot \text{K} \times 0.020 \text{ m} / 15 \text{ W/m} \cdot \text{K} = 0.67$$

Since $Bi \gg 0.1$, we expect an appreciable temperature difference between the mid-plane and surface as the tabulated results indicate (Eq. 5.10).

(b) The results are tabulated below for the wall temperatures using the lumped capacitance method (LCM) of solution, Eq. 5.6. The LCM neglects the internal conduction resistance and since $Bi = 0.67 \gg 0.1$, we expect this method to predict systematically lower temperatures (faster cooling) at the midplane compared to the one-term approximation.

Solution method/Time(s)	50	100	200	500
<u>Mid-plane, $T(0,t)$ ($^{\circ}\text{C}$)</u>				
One-term, Eqs. 5.40, 5.41	207.1	160.5	99.97	37.70
Lumped capacitance	181.7	133.9	77.69	30.97
2-node FDE	210.6	163.5	100.5	37.17
5-node FDE	207.5	160.9	100.2	37.77
<u>Surface, $T(L,t)$ ($^{\circ}\text{C}$)</u>				
One-term, Eqs. 5.40, 5.41	160.1	125.4	80.56	34.41
Lumped capacitance	181.7	133.9	77.69	30.97
2-node FDE	163.7	125.2	79.40	33.77
5-node FDE	160.2	125.6	80.67	34.45

(c) The 2- and 5-node nodal networks representing the wall are shown in the schematic above. The implicit form of the finite-difference equations for the mid-plane, interior (if present) and surface nodes can be derived from energy balances on the nodal control volumes. The time-rate of change of the temperature is expressed in terms of the *IHT* integral intrinsic function, $der(T,t)$.

Continued

PROBLEM 5.111 (Cont.)

Mid-plane node

$$k(T_2 - T_1) / \Delta x = \rho c (\Delta x / 2) \cdot \text{der}(T_1, t)$$

Interior node (5-node network)

$$k(T_1 - T_2) / \Delta x + k(T_3 - T_2) / \Delta x = \rho c \Delta x \cdot \text{der}(T_2, t)$$

Surface node (shown for 5-node network)

$$k(T_4 - T_5) / \Delta x + h(T_{\text{inf}} - T_5) = \rho c (\Delta x / 2) \cdot \text{der}(T_5, t)$$

With appropriate values for Δx , the foregoing FDEs were entered into the *IHT* workspace and solved for the temperature distributions as a function of time over the range $0 \leq t \leq 500$ s using an integration time step of 1 s. Selected portions of the *IHT* codes for each of the models are shown in the Comments. The results of the analysis are summarized in the foregoing table.

COMMENTS: (1) Referring to the table above, we can make the following observations about the relative differences and similarities of the estimated temperatures: (a) The one-term series model estimates are the most reliable, and can serve as the benchmark for the other model results; (b) The LCM model over estimates the rate of cooling, and poorly predicts temperatures since the model neglects the effect of internal resistance and $Bi = 0.67 \gg 0.1$; (c) The 5-node model results are in excellent agreement with those from the one-term series solution; we can infer that the chosen space and time increments are sufficiently small to provide accurate results; and (d) The 2-node model under estimates the rate of cooling for early times when the time-rate of change is high; but for late times, the agreement is improved.

(2) See the *Solver / Intrinsic Functions* section of *IHT/Help* or the *IHT Examples* menu (Example 5.3) for guidance on using the $\text{der}(T, t)$ function.

(3) Selected portions of the *IHT* code for the 2-node network model are shown below.

```
// Writing the finite-difference equations – 2-node model
// Node 1
k * (T2 - T1) / deltax = rho * cp * (deltax / 2) * der(T1,t)
// Node 2
k * (T1 - T2) / deltax + h * (Tinf - T2) = rho * cp * (deltax / 2) * der(T2,t)

// Input parameters
L = 0.020
deltax = L
rho = 7800      // density, kg/m^3
cp = 440        // specific heat, J/kg·K
k = 15          // thermal conductivity, W/m·K
h = 500         // convection coefficient, W/m^2·K
Tinf = 25       // fluid temperature, K
```

(4) Selected portions of the *IHT* code for the 5-node network model are shown below.

```
// Writing the finite-difference equations – 5-node model
// Node 1 - midplane
k * (T2 - T1) / deltax = rho * cp * (deltax / 2) * der(T1,t)
// Interior nodes
k * (T1 - T2) / deltax + k * (T3 - T2) / deltax = rho * cp * deltax * der(T2,t)
k * (T2 - T3) / deltax + k * (T4 - T3) / deltax = rho * cp * deltax * der(T3,t)
k * (T3 - T4) / deltax + k * (T5 - T4) / deltax = rho * cp * deltax * der(T4,t)
// Node5 - surface

PROBLEM 5.112

KNOWN: Plastic film on metal strip initially at 25°C is heated by a laser (85,000 W/m² for $\Delta t_{\text{on}} = 10$ s), to cure adhesive; convection conditions for ambient air at 25°C with coefficient of 100 W/m²·K.

FIND: Temperature histories at center and film edge, $T(0,t)$ and $T(x_1,t)$, for $0 \leq t \leq 30$ s, using an implicit, finite-difference method with $\Delta x = 4$ mm and $\Delta t = 1$ s; determine whether adhesive is cured ($T_c \geq 90^\circ\text{C}$ for $\Delta t_c = 10$ s) and whether the degradation temperature of 200°C is exceeded.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Uniform convection coefficient on upper and lower surfaces, (4) Thermal resistance and mass of plastic film are negligible, (5) All incident laser flux is absorbed.

PROPERTIES: Metal strip (given): $\rho = 7850$ kg/m³, $c_p = 435$ J/kg·K, $k = 60$ W/m·K, $\alpha = k/\rho c_p = 1.757 \times 10^{-5}$ m²/s.

ANALYSIS: (a) Using a space increment of $\Delta x = 4$ mm, set up the nodal network shown below. Note that the film half-length is 22 mm (rather than 20 mm as in Problem 3.97) to simplify the finite-difference equation derivation.

Consider the general control volume and use the conservation of energy requirement to obtain the finite-difference equation.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$$

$$q_a + q_b + q_{\text{laser}} + q_{\text{conv}} = M c_p \frac{T_m^{p+1} - T_m^p}{\Delta t}$$

Continued

PROBLEM 5.112 (Cont.)

$$\begin{aligned}
 & k(d \cdot 1) \frac{T_{m-1}^{p+1} - T_m^{p+1}}{\Delta x} + k(d \cdot 1) \frac{T_{m+1}^{p+1} - T_m^{p+1}}{\Delta x} \\
 & + q_o''(\Delta x \cdot 1) + 2h(\Delta x \cdot 1)(T_\infty - T_m^{p+1}) = \rho(\Delta x \cdot d \cdot 1) c_p \frac{T_m^{p+1} - T_m^p}{\Delta t} \\
 & T_m^p = (1 + 2Fo + 2Fo \cdot Bi) T_m^{p+1} \\
 & - Fo(T_{m+1}^{p+1} + T_{m-1}^{p+1}) - 2Fo \cdot Bi \cdot T_\infty - Fo \cdot Q
 \end{aligned} \tag{1}$$

where

$$Fo = \frac{\alpha \Delta t}{\Delta x^2} = \frac{1.757 \times 10^{-5} \text{ m}^2/\text{s} \times 1 \text{ s}}{(0.004 \text{ m})^2} = 1.098 \tag{2}$$

$$Bi = \frac{h(\Delta x^2/d)}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} (0.004^2/0.00125) \text{ m}}{60 \text{ W/m} \cdot \text{K}} = 0.0213 \tag{3}$$

$$Q = \frac{q_o''(\Delta x^2/d)}{k} = \frac{85,000 \text{ W/m}^2 (0.004^2/0.00125) \text{ m}}{60 \text{ W/m} \cdot \text{K}} = 18.133. \tag{4}$$

The results of the matrix inversion numerical method of solution ($\Delta x = 4 \text{ mm}$, $\Delta t = 1 \text{ s}$) are shown below. The temperature histories for the center ($m = 1$) and film edge ($m = 5$) nodes, $T(0, t)$ and $T(x_1, t)$, respectively, permit determining whether the adhesive has cured ($T \geq 90^\circ\text{C}$ for 10 s).

Certainly the center region, $T(0, t)$, is fully cured and furthermore, the degradation temperature (200°C) has not been exceeded. From the $T(x_1, t)$ distribution, note that $\Delta t_c \approx 8 \text{ sec}$, which is 20% less than the 10 s interval sought. Hence, the laser exposure (now 10 s) should be slightly increased and quite likely, the maximum temperature will not exceed 200°C .

PROBLEM 5.113

KNOWN: Insulated rod of prescribed length and diameter, with one end in a fixture at 200°C, reaches a uniform temperature. Suddenly the insulating sleeve is removed and the rod is subjected to a convection process.

FIND: (a) Time required for the mid-length of the rod to reach 100°C, (b) Temperature history $T(x, t \leq t_1)$, where t_1 is time at which the midlength reaches 50°C. Temperature distribution at 0, 200s, 400s and t_1 .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction in rod, (2) Uniform h along rod and at end, (3) Negligible radiation exchange between rod and surroundings, (4) Constant properties.

ANALYSIS: (a) Choosing $\Delta x = 0.016$ m, the finite-difference equations for the interior and end nodes are obtained.

Interior Point, m :
$$q_a + q_b + q_c = \rho \cdot A_c \Delta x \cdot c_p \cdot \frac{T_m^{p+1} - T_m^p}{\Delta t}$$

$$k \cdot A_c \frac{T_{m-1}^p - T_m^p}{\Delta x} + k A_c \frac{T_{m+1}^p - T_m^p}{\Delta x} + h P \Delta x (T_\infty - T_m^p) = \rho A_c \Delta x c_p \frac{T_m^{p+1} - T_m^p}{\Delta t}$$

Regrouping,

$$T_m^{p+1} = T_m^p (1 - 2Fo - Bi \cdot Fo) + Fo (T_{m-1}^p + T_{m+1}^p) + Bi \cdot Fo T_\infty \quad (1)$$

where

$$Fo = \frac{\alpha \Delta t}{\Delta x^2} \quad (2)$$

$$Bi = h \left[\Delta x^2 / (A_c / P) \right] / k. \quad (3)$$

From Eq. (1), recognize that the stability of the numerical solution will be assured when the first term on the RHS is positive; that is

Continued...

PROBLEM 5.113 (Cont.)

$$(1 - 2Fo - Bi \cdot Fo) \geq 0 \quad \text{or} \quad Fo \leq 1/(2 + Bi). \quad (4)$$

Nodal Point 1: Consider Eq. (1) for the special case that $T_{m-1}^p = T_o$, which is independent of time.

Hence,

$$T_1^{p+1} = T_1^p (1 - 2Fo - Bi \cdot Fo) + Fo(T_o + T_2^p) + Bi \cdot Fo T_o. \quad (5)$$

End Nodal Point 10: $q_a + q_b + q_c = \rho \cdot A_c \frac{\Delta x}{2} \cdot c_p \frac{T_{10}^{p+1} - T_{10}^p}{\Delta t}$

$$k \cdot A_c \frac{T_9^p - T_{10}^p}{\Delta x} + hA_c (T_o - T_{10}^p) + hP \frac{\Delta x}{2} (T_o - T_{10}^p) = \rho A_c \frac{\Delta x}{2} c_p \frac{T_{10}^{p+1} - T_{10}^p}{\Delta t}$$

Regrouping, $T_{10}^{p+1} = T_{10}^p (1 - 2Fo - 2N \cdot Fo - Bi \cdot Fo) + 2FoT_9^p + T_o (2N \cdot Fo + Bi \cdot Fo)$ (6)

where $N = h\Delta x/k$. (7)

The stability criterion is $Fo \leq 1/2(1 + N + Bi/2)$. (8)

With the finite-difference equations established, we can now proceed with the numerical solution.

Having already specified $\Delta x = 0.016$ m, Bi can now be evaluated. Noting that $A_c = \pi D^2/4$ and $P = \pi D$, giving $A_c/P = D/4$, Eq. (3) yields

$$Bi = 30 \text{ W/m}^2 \cdot \text{K} \left[(0.016 \text{ m})^2 / \frac{0.010 \text{ m}}{4} \right] / 14.8 \text{ W/m} \cdot \text{K} = 0.208 \quad (9)$$

From the stability criteria, Eqs. (4) and (8), for the finite-difference equations, it is recognized that Eq. (8) requires the greater value of Fo. Hence

$$Fo = \frac{1}{2} \left(1 + 0.0324 + \frac{0.208}{2} \right) = 0.440 \quad (10)$$

where from Eq. (7), $N = \frac{30 \text{ W/m}^2 \cdot \text{K} \times 0.016 \text{ m}}{14.8 \text{ W/m} \cdot \text{K}} = 0.0324$. (11)

From the definition of Fo, Eq. (2), we obtain the time increment

$$\Delta t = \frac{Fo(\Delta x)^2}{\alpha} = 0.440(0.016 \text{ m})^2 / 3.63 \times 10^{-6} \text{ m}^2/\text{s} = 31.1 \text{ s} \quad (12)$$

and the time relation is $t = p\Delta t = 31.1t$. (13)

Using the numerical values for Fo, Bi and N, the finite-difference equations can now be written ($^{\circ}\text{C}$).

Nodal Point m ($2 \leq m \leq 9$):

$$\begin{aligned} T_m^{p+1} &= T_m^p (1 - 2 \times 0.440 - 0.208 \times 0.440) + 0.440(T_{m-1}^p + T_{m+1}^p) + 0.208 \times 0.440 \times 25 \\ T_m^{p+1} &= 0.029T_m^p + 0.440(T_{m-1}^p + T_{m+1}^p) + 2.3 \end{aligned} \quad (14)$$

Nodal Point 1:

$$T_1^{p+1} = 0.029T_1^p + 0.440(200 + T_2^p) + 2.3 = 0.029T_1^p + 0.440T_2^p + 90.3 \quad (15)$$

Nodal Point 10:

$$T_{10}^{p+1} = 0 \times T_{10}^p + 2 \times 0.440T_9^p + 25(2 \times 0.0324 \times 0.440 + 0.208 \times 0.440) = 0.880T_9^p + 3.0 \quad (16)$$

Continued...

PROBLEM 5.113 (Cont.)

Using finite-difference equations (14-16) with Eq. (13), the calculations may be performed to obtain

p	t(s)	T ₁	T ₂	T ₃	T ₄	T ₅	T ₆	T ₇	T ₈	T ₉	T ₁₀ (°C)
0	0	200	200	200	200	200	200	200	200	200	200
1	31.1	184.1	181.8	181.8	181.8	181.8	181.8	181.8	181.8	181.8	179.0
2	62.2	175.6	166.3	165.3	165.3	165.3	165.3	165.3	165.3	164.0	163.0
3	93.3	168.6	154.8	150.7	150.7	150.7	150.7	150.7	149.7	149.2	147.3
4	124.4	163.3	145.0	138.8	137.0	137.0	137.0	136.5	136.3	135.0	134.3
5	155.5	158.8	137.1	128.1	125.3	124.5	124.3	124.2	123.4	123.0	121.8
6	186.6	155.2	130.2	119.2	114.8	113.4	113.0	112.6	112.3	111.5	111.2
7	217.7	152.1	124.5	111.3	105.7	103.5	102.9	102.4			
8	248.8	145.1	119.5	104.5	97.6	94.8					

Using linear interpolation between rows 7 and 8, we obtain $T(L/2, 230s) = T_5 \approx 100^\circ\text{C}$. <

(b) Using the option concerning *Finite-Difference Equations for One-Dimensional Transient Conduction in Extended Surfaces* from the IHT Toolpad, the desired temperature histories were computed for $0 \leq t \leq t_1 = 930s$. A *Lookup Table* involving data for $T(x)$ at $t = 0, 200, 400$ and $930s$ was created.

t(s)/x(mm)	0	16	32	48	64	80	96	112	128	144	160
0	200	200	200	200	200	200	200	200	200	200	200
200	200	157.8	136.7	127.0	122.7	121.0	120.2	119.6	118.6	117.1	114.7
400	200	146.2	114.9	97.32	87.7	82.57	79.8	78.14	76.87	75.6	74.13
930	200	138.1	99.23	74.98	59.94	50.67	44.99	41.53	39.44	38.2	37.55

and the *LOOKUPVAL2* interpolating function was used with the *Explore* and *Graph* feature of IHT to create the desired plot.

Temperatures decrease with increasing x and t , and except for early times ($t < 200s$) and locations in proximity to the fin tip, the magnitude of the temperature gradient, $|dT/dx|$, decreases with increasing x . The slight increase in $|dT/dx|$ observed for $t = 200s$ and $x \rightarrow 160$ mm is attributable to significant heat loss from the fin tip.

COMMENTS: The steady-state condition may be obtained by extending the finite-difference calculations in time to $t \approx 2650s$ or from Eq. 3.70.

PROBLEM 5.114

KNOWN: Tantalum rod initially at a uniform temperature, 300K, is suddenly subjected to a current flow of 80A; surroundings (vacuum enclosure) and electrodes maintained at 300K.

FIND: (a) Estimate time required for mid-length to reach 1000K, (b) Determine the steady-state temperature distribution and estimate how long it will take to reach steady-state. Use a finite-difference method with a space increment of 10mm.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in rod, (2) Surroundings are much larger than rod, (3) Properties are constant and evaluated at an average temperature.

PROPERTIES: Table A-1, Tantalum ($\bar{T} = (300 + 1000) \text{ K} / 2 = 650 \text{ K}$): $\rho = 16,600 \text{ kg/m}^3$, $c = 147 \text{ J/kg}\cdot\text{K}$, $k = 58.8 \text{ W/m}\cdot\text{K}$, and $\alpha = k/\rho c = 58.8 \text{ W/m}\cdot\text{K} / 16,600 \text{ kg/m}^3 \times 147 \text{ J/kg}\cdot\text{K} = 2.410 \times 10^{-5} \text{ m}^2/\text{s}$.

ANALYSIS: From the derivation of the previous problem, the finite-difference equation was found to be

$$T_m^{p+1} = \text{Fo} \left(T_{m-1}^p + T_{m+1}^p \right) + (1 - 2\text{Fo}) T_m^p - \frac{\varepsilon P \sigma \Delta x^2}{k A_c} \text{Fo} \left(T_m^{4,p} - T_{\text{sur}}^4 \right) + \frac{I^2 \rho_e \Delta x^2}{k A_c^2} \cdot \text{Fo} \quad (1)$$

where $\text{Fo} = \alpha \Delta t / \Delta x^2$ $A_c = \pi D^2 / 4$ $P = \pi D$. (2,3,4)

From the stability criterion, let $\text{Fo} = 1/2$ and numerically evaluate terms of Eq. (1).

$$\begin{aligned} T_m^{p+1} &= \frac{1}{2} \left(T_{m-1}^p + T_{m+1}^p \right) - \frac{0.1 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (0.01 \text{ m})^2}{58.8 \text{ W/m}\cdot\text{K} \times (\pi (0.003 \text{ m})^2 / 4)} \cdot \frac{1}{2} \left(T_m^{4,p} - [300 \text{ K}]^4 \right) + \\ &\quad + \frac{(80 \text{ A})^2 \times 95 \times 10^{-8} \Omega \cdot \text{m} \times (0.01 \text{ m})^2}{58.8 \text{ W/m}\cdot\text{K} \left(\pi [0.003 \text{ m}]^2 / 4 \right)^2} \cdot \frac{1}{2} \\ T_m^{p+1} &= \frac{1}{2} \left(T_{m-1}^p + T_{m+1}^p \right) - 6.4285 \times 10^{-12} T_m^{4,p} + 103.53. \end{aligned} \quad (5)$$

Note that this form applies to nodes 0 through 5. For node 0, $T_{m-1} = T_{m+1} = T_1$. Since $\text{Fo} = 1/2$, using Eq. (2), find that

$$\Delta t = \Delta x^2 \text{Fo} / \alpha = (0.01 \text{ m})^2 \times 1/2 / 2.410 \times 10^{-5} \text{ m}^2/\text{s} = 2.07 \text{ s}. \quad (6)$$

Hence, $t = p \Delta t = 2.07 \text{ p}$. (7)

Continued

PROBLEM 5.114 (Cont.)

(a) To estimate the time required for the mid-length to reach 1000K, that is $T_0 = 1000\text{K}$, perform the forward-marching solution beginning with $T_i = 300\text{K}$ at $p = 0$. The solution, as tabulated below, utilizes Eq. (5) for successive values of p . Elapsed time is determined by Eq. (7).

P	t(s)	T_0	T_1	T_2	T_3	T_4	T_5	$T_6(^{\circ}\text{C})$
0	0	300	300	300	300	300	300	300
1		403.5	403.5	403.5	403.5	403.5	403.5	300
2		506.9	506.9	506.9	506.9	506.9	455.1	300
3		610.0	610.0	610.0	610.0	584.1	506.7	300
4		712.6	712.6	712.6	699.7	661.1	545.2	300

6		915.2	911.9	902.4	867.4	787.9	615.1	300
7		1010.9	1007.9	988.9	945.0	842.3	646.6	300
8		1104.7	1096.8	1073.8	1014.0	896.1	673.6	300
9		1190.9	1183.5	1150.4	1081.7	943.2	700.3	300
10	20.7	1274.1	1261.6	1224.9	1141.5	989.4	723.6	300
11		1348.2	1336.7	1290.6	1199.8	1029.9	746.5	300
12		1419.7	1402.4	1353.9	1250.5	1069.4	766.5	300
13		1479.8	1465.5	1408.4	1299.8	1103.6	786.0	300
14		1542.6	1538.2	1460.9	1341.2	1136.9	802.9	300
15	31.1	1605.3	1569.3	1514.0	1381.6	1164.8	819.3	300

Note that, at $p \approx 6.9$ or $t = 6.9 \times 2.07 = 14.3\text{s}$, the mid-point temperature is $T_0 \approx 1000\text{K}$. <

(b) The steady-state temperature distribution can be obtained by continuing the marching solution until only small changes in T_m are noted. From the table above, note that at $p = 15$ or $t = 31\text{s}$, the temperature distribution is still changing with time. It is likely that at least 15 more calculation sets are required to see whether steady-state is being approached.

COMMENTS: (1) This problem should be solved with a computer rather than a hand-calculator. For such a situation, it would be appropriate to decrease the spatial increment in order to obtain better estimates of the temperature distribution.

(2) If the rod were very long, the steady-state temperature distribution would be very flat at the mid-length $x = 0$. Performing an energy balance on the small control volume shown to the right, find

$$\dot{E}_g - \dot{E}_{out} = 0$$

$$I^2 \frac{\rho_e \Delta x}{A_c} - \varepsilon \sigma P \Delta x (T_0^4 - T_{sur}^4) = 0.$$

Substituting numerical values, find $T_0 = 2003\text{K}$. It is unlikely that the present rod would ever reach this steady-state, maximum temperature. That is, the effect of conduction along the rod will cause the center temperature to be less than this value.

PROBLEM 5.115

KNOWN: Support rod spanning a channel whose walls are maintained at $T_b = 300$ K. Suddenly the rod is exposed to cross flow of hot gases with $T_\infty = 600$ K and $h = 75$ W/m²·K. After the rod reaches steady-state conditions, the hot gas flow is terminated and the rod cools by free convection and radiation exchange with surroundings.

FIND: (a) Compute and plot the midspan temperature as a function of elapsed heating time; compare the steady-state temperature distribution with results from an analytical model of the rod and (b) Compute the midspan temperature as a function of elapsed cooling time and determine the time required for the rod to reach the safe-to-touch temperature of 315 K.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in rod, (2) Constant properties, (3) During heating process, uniform convection coefficient over rod, (4) During cooling process, free convection coefficient is of the form $h = C\Delta T^n$ where $C = 4.4$ W/m²·K^{1.188} and $n = 0.188$, and (5) During cooling process, surroundings are large with respect to the rod.

ANALYSIS: (a) The finite-difference equations for the 10-node mesh shown above can be obtained using the *IHT Finite-Difference Equation, One-Dimensional, Transient Extended Surfaces Tool*. The temperature-time history for the midspan position T_{10} is shown in the plot below. The steady-state temperature distribution for the rod can be determined from Eq. 3.75, Case B, Table 3.4. This case is treated in the *IHT Extended Surfaces Model, Temperature Distribution and Heat Rate, Rectangular Pin Fin*, for the adiabatic tip condition. The following table compares the steady-state temperature distributions for the numerical and analytical methods.

Method	Temperatures (K) vs. Position x (mm)					
	0	10	20	30	40	50
Analytical	300	386.1	443.4	479.5	499.4	505.8
Numerical	300	386.0	443.2	479.3	499.2	505.6

The comparison is excellent indicating that the nodal mesh is sufficiently fine to obtain precise results.

Continued...

PROBLEM 5.115 (Cont.)

(b) The same finite-difference approach can be used to model the cooling process. In using the IHT tool, the following procedure was used: (1) Set up the FDEs with the convection coefficient expressed as $h_m = h_{fc,m} + h_{r,m}$, the sum of the free convection and linearized radiation coefficients based upon nodal temperature T_m .

$$h_{fc,m} = C(T_m^p - T_\infty)$$

$$h_{r,m} = \varepsilon\sigma(T_m^p + T_{sur})\left((T_m^p)^2 + T_{sur}^2\right)$$

(2) For the initial solve, set $h_{fc,m} = h_{r,m} = 5 \text{ W/m}^2\cdot\text{K}$ and solve, (3) Using the solved results as the Initial Guesses for the next solve, allow $h_{fc,m}$ and $h_{r,m}$ to be unknowns. The temperature-time history for the midspan during the cooling process is shown in the plot below. The time to reach the safe-to-touch temperature, $T_{10}^p = 315 \text{ K}$, is

$$t = 550 \text{ s}$$

<

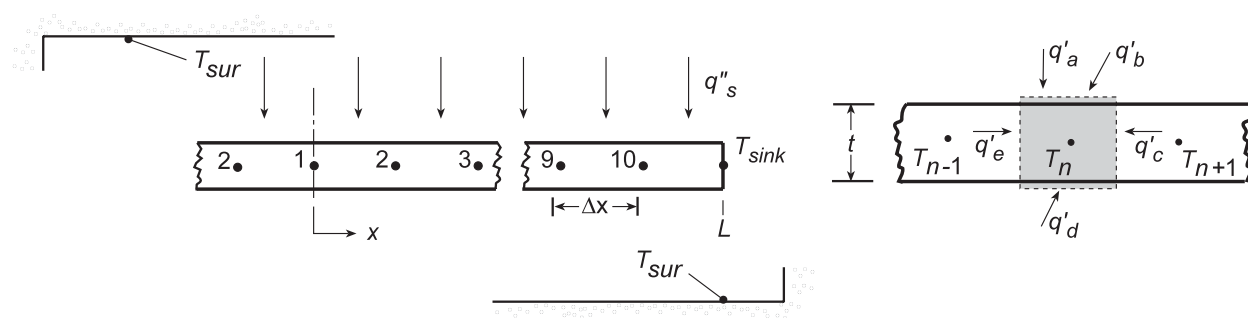

PROBLEM 5.116

KNOWN: Thin metallic foil of thickness, w , whose edges are thermally coupled to a sink at temperature, T_{sink} , initially at a uniform temperature $T_i = T_{\text{sink}}$, is suddenly exposed on the top surface to an ion beam heat flux, q''_s , and experiences radiation exchange with the vacuum enclosure walls at T_{sur} . Consider also the situation when the foil is operating under steady-state conditions when suddenly the ion beam is deactivated.

FIND: (a) Compute and plot the midspan temperature-time history during the *heating* process; determine the elapsed time that this point on the foil reaches a temperature within 1 K of the steady-state value, and (b) Compute and plot the midspan temperature-time history during the *cooling* process from steady-state operation; determine the elapsed time that this point on the foil reaches the *safe-to-touch* temperature of 315 K.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in the foil, (2) Constant properties, (3) Upper and lower surfaces of foil experience radiation exchange with the large surroundings, (4) Ion beam incident on upper surface only, (4) Foil is of unit width normal to the page.

ANALYSIS: (a) The finite-difference equations for the 10-node mesh shown above can be obtained using the *IHT Finite-Difference Equation, One-Dimensional, Transient, Extended Surfaces Tool*. In formulating the energy-balance functions, the following steps were taken: (1) the FDE function coefficient h must be identified for each node, e.g., h_1 and (2) coefficient can be represented by the linearized radiation coefficient, e.g., $h_1 = \epsilon\sigma(T_1 + T_{\text{sur}})(T_1^2 + T_{\text{sur}}^2)$, (3) set $q''_a = q''_0/2$ since the ion beam is incident on only the top surface of the foil, and (4) when solving, the initial condition corresponds to $T_i = 300$ K for each node. The temperature-time history of the midspan position is shown below. The time to reach within 1 K of the steady-state temperature (374.1 K) is

$$T_{10}(t_h) = 373 \text{ K} \quad t_h = 136 \text{ s} \quad \angle$$

(b) The same IHT workspace may be used to obtain the temperature-time history for the cooling process by taking these steps: (1) set $q''_s = 0$, (2) specify the initial conditions as the steady-state temperature (K) distribution tabulated below,

T_1	T_2	T_3	T_4	T_5	T_6	T_7	T_8	T_9	T_{10}
374.1	374.0	373.5	372.5	370.9	368.2	363.7	356.6	345.3	327.4

(3) when performing the integration of the independent time variable, set the start value as 200 s and (4) save the results for the heating process in Data Set A. The temperature-time history for the heating and cooling processes can be made using Data Browser results from the Working and A Data Sets. The time required for the midspan to reach the *safe-to-touch* temperature is

$$T_{10}(t_c) = 315 \text{ K} \quad t_c = 73 \text{ s} \quad \angle$$

PROBLEM 5.117

KNOWN: Stack or book of steel plates (sp) and circuit boards (b) subjected to a prescribed platen heating schedule $T_p(t)$. See Problem 5.46 for other details of the book.

FIND: (a) Using the implicit numerical method with $\Delta x = 2.36\text{mm}$ and $\Delta t = 60\text{s}$, find the mid-plane temperature $T(0,t)$ of the book and determine whether curing will occur ($> 170^\circ\text{C}$ for 5 minutes), (b) Determine how long it will take $T(0,t)$ to reach 37°C following reduction of the platen temperature to 15°C (at $t = 50$ minutes), (c) Validate code by using a sudden change of platen temperature from 15 to 190°C and compare with the solution of Problem 5.38.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible contact resistance between plates, boards and platens.

PROPERTIES: Steel plates (sp, given): $\rho_{sp} = 8000\text{ kg/m}^3$, $c_{p,sp} = 480\text{ J/kg}\cdot\text{K}$, $k_{sp} = 12\text{ W/m}\cdot\text{K}$; Circuit boards (b, given): $\rho_b = 1000\text{ kg/m}^3$, $c_{p,b} = 1500\text{ J/kg}\cdot\text{K}$, $k_b = 0.30\text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) Using the suggested space increment $\Delta x = 2.36\text{mm}$, the model grid spacing treating the steel plates (sp) and circuit boards (b) as discrete elements, we need to derive the nodal equations for the interior nodes (2-11) and the node next to the platen (1). Begin by defining appropriate control volumes and apply the conservation of energy requirement.

Effective thermal conductivity, k_e : Consider an adjacent steel plate-board arrangement. The thermal resistance between the nodes i and j is

$$R''_{ij} = \frac{\Delta x}{k_e} = \frac{\Delta x/2}{k_b} + \frac{\Delta x/2}{k_{sp}}$$

$$k_e = \frac{2}{1/k_b + 1/k_{sp}} = \frac{2}{1/0.3 + 1/12}\text{ W/m}\cdot\text{K}$$

$$k_e = 0.585\text{ W/m}\cdot\text{K}.$$

Odd-numbered nodes, $3 \leq m \leq 11$ - steel plates (sp): Treat as interior nodes using Eq. 5.94 with

$$\alpha_{sp} \equiv \frac{k_e}{\rho_{sp} c_{sp}} = \frac{0.585\text{ W/m}\cdot\text{K}}{8000\text{ kg/m}^3 \times 480\text{ J/kg}\cdot\text{K}} = 1.523 \times 10^{-7}\text{ m}^2/\text{s}$$

$$Fo_m = \frac{\alpha_{sp} \Delta t}{\Delta x^2} = \frac{1.523 \times 10^{-7}\text{ m}^2/\text{s} \times 60\text{ s}}{(0.00236\text{ m})^2} = 1.641$$

Continued

PROBLEM 5.117 (Cont.)

to obtain, with m as odd-numbered,

$$(1 + 2Fo_m)T_m^{p+1} - Fo_m(T_{m-1}^{p+1} + T_{m+1}^{p+1}) = T_m^p \quad (1)$$

Even-numbered nodes, $2 \leq n \leq 10$ - circuit boards (b): Using Eq. 5.94 and evaluating α_b and Fo_n

$$\alpha_b = \frac{k_e}{\rho_b c_b} = 3.900 \times 10^{-7} \text{ m}^2/\text{s} \quad Fo_n = 4.201$$

$$(1 + 2Fo_n)T_n^{p+1} - Fo_n(T_{n-1}^{p+1} + T_{n+1}^{p+1}) = T_n^p \quad (2)$$

Plate next to platen, $n = 1$ - steel plate (sp): The finite-difference equation for the plate node ($n = 1$) next to the platen follows from a control volume analysis.

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$$

$$q_a'' + q_b'' = \rho_{sp} \Delta x c_{sp} \frac{T_1^{p+1} - T_1^p}{\Delta t}$$

where

$$q_a'' = k_{sp} \frac{T_p(t) - T_1^{p+1}}{\Delta x/2} \quad q_b'' = k_e \frac{T_2^{p+1} - T_1^{p+1}}{\Delta x}$$

and $T_p(t) = T_p(p)$ is the platen temperature which is changed with time according to the heating schedule. Regrouping find,

$$\left(1 + Fo_m \left(1 + \frac{2k_{sp}}{k_e} \right) \right) T_1^{p+1} - Fo_m T_2^{p+1} - \frac{2k_{sp}}{k_e} Fo_m T_p(p) = T_1^p \quad (3)$$

where $2k_{sp}/k_e = 2 \times 12 \text{ W/m}\cdot\text{K} / 0.585 \text{ W/m}\cdot\text{K} = 41.03$.

Using the nodal Eqs. (1) -(3), an inversion method of solution was effected and the temperature distributions are shown on the following page.

Temperature distributions - discussion: As expected, the temperatures of the nodes near the center of the book considerably lag those nearer the platen. The criterion for cure is $T \geq 170^\circ\text{C} = 443 \text{ K}$ for $\Delta t_c = 5 \text{ min} = 300 \text{ sec}$. From the temperature distributions, note that node 10 just reaches 443 K after 50 minutes and will not be cured. It appears that the region about node 5 will be cured.

(b) The time required for the book to reach $37^\circ\text{C} = 310 \text{ K}$ can likewise be seen from the temperature distribution results. The plates/boards nearest the platen will cool to the safe handling temperature with $1000 \text{ s} = 16 \text{ min}$, but those near the center of the stack will require in excess of $2000 \text{ s} = 32 \text{ min}$.

Continued

PROBLEM 5.117 (Cont.)

(c) It is important when validating computer codes to have the program work a “problem” which has an exact analytical solution. You should select the problem such that all features of the code are tested.

PROBLEM 5.118

KNOWN: Reaction and composite clutch plates, initially at a uniform temperature, $T_i = 40^\circ\text{C}$, are subjected to the frictional-heat flux shown in the engagement energy curve, q_f'' vs. t .

FIND: (a) On T - t coordinates, sketch the temperature histories at the mid-plane of the reaction plate, at the interface between the clutch pair, and at the mid-plane of the composite plate; identify key features; (b) Perform an energy balance on the clutch pair over a time interval basis and calculate the steady-state temperature resulting from a clutch engagement; (c) Obtain the temperature histories using the finite-element approach with *FEHT* and the finite-difference method of solution with *IHT* ($\Delta x = 0.1$ mm and $\Delta t = 1$ ms). Calculate and plot the frictional heat fluxes to the reaction and composite plates, q_{rp}'' and q_{cp}'' , respectively, as a function of time. Comment on the features of the temperature and frictional-heat flux histories.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible heat transfer to the surroundings.

PROPERTIES: Steel, $\rho_s = 7800$ kg/m³, $c_s = 500$ J/kg·K, $k_s = 40$ W/m·K; Friction material, $\rho_{fm} = 1150$ kg/m³, $c_{fm} = 1650$ J/kg·K, and $k_{fm} = 4$ W/m·K.

ANALYSIS: (a) The temperature histories for specified locations in the system are sketched on T - t coordinates below.

Initially, the temperature at all locations is uniform at T_i . Since there is negligible heat transfer to the surroundings, eventually the system will reach a uniform, steady-state temperature $T(\infty)$. During the engagement period, the interface temperature increases much more rapidly than at the mid-planes of the reaction (rp) and composite (cp) plates. The interface temperature should be the maximum within the system and could occur before lock-up, $t = t_{lu}$.

Continued

PROBLEM 5.118 (Cont.)

(b) To determine the steady-state temperature following the engagement period, apply the conservation of energy requirement on the clutch pair on a time-interval basis, Eq. 1.11b.

The final and initial states correspond to uniform temperatures of $T(\infty)$ and T_i , respectively. The energy input is determined from the engagement energy curve, q_f'' vs. t .

$$E_{in}'' - E_{out}'' + E_{gen}'' = \Delta E_{st}'' \quad E_{in}'' = E_{out}'' = 0$$

$$\int_0^{t_{lu}} q_f''(t) dt = E_f'' - E_i'' = \left[\rho_s c_s (L_{rp}/2 + L_{cp}/2) + \rho_{fm} c_{fm} L_{fm} \right] (T_f - T_i)$$

Substituting numerical values, with $T_i = 40^\circ\text{C}$ and $T_f = T(\infty)$.

$$0.5 q_o'' t_{lu} = \left[\rho_s c_s (L_{rp}/2 + L_{cp}/2) + \rho_{fm} c_{fm} L_{fm} \right] (T(\infty) - T_i)$$

$$0.5 \times 1.6 \times 10^7 \text{ W/m}^2 \times 0.100 \text{ s} = \left[7800 \text{ kg/m}^3 \times 500 \text{ J/kg} \cdot \text{K} (0.001 + 0.0005) \text{ m} + 1150 \text{ kg/m}^3 \times 1650 \text{ J/kg} \cdot \text{K} \times 0.0005 \text{ m} \right] (T(\infty) - 40)^\circ\text{C}$$

$$T(\infty) = 158^\circ\text{C}$$

<

(c) *Finite-element method of solution, FEHT.* The clutch pair is comprised of the reaction plate (1 mm), an interface region (0.1 mm), and the composite plate (cp) as shown below.

Continued (2)...

PROBLEM 5.118 (Cont.)

The external boundaries of the system are made adiabatic. The interface region provides the means to represent the frictional heat flux, specified with negligible thermal resistance and capacitance. The generation rate is prescribed as

$$\dot{q} = 1.6 \times 10^{11} (1 - \text{Time} / 0.1) \text{ W} / \text{m}^3 \quad 0 \leq \text{Time} \leq t_{lu}$$

where the first coefficient is evaluated as $q_o'' / 0.1 \times 10^{-3} \text{ m}$ and the 0.1 mm parameter is the thickness of the region. Using the *Run* command, the integration is performed from 0 to 0.1 s with a time step of $1 \times 10^{-6} \text{ s}$. Then, using the *Specify/Generation* command, the generation rate is set to zero and the *Run/Continue* command is executed. The temperature history is shown below.

(c) *Finite-difference method of solution, IHT.* The nodal arrangement for the clutch pair is shown below with $\Delta x = 0.1 \text{ mm}$ and $\Delta t = 1 \text{ ms}$. Nodes 02-10, 13-16 and 18-21 are interior nodes, and their finite-difference equations (FDE) can be called into the *Workspace* using *Tools/Finite Difference Equations/One-Dimensional/Transient*. Nodes 01 and 22 represent the mid-planes for the reaction and composite plates, respectively, with adiabatic boundaries. The FDE for node 17 is derived from an energy balance on its control volume (CV) considering different properties in each half of the CV. The FDE for node 11 and 12 are likewise derived using energy balances on their CVs. At the interface, the following conditions must be satisfied

$$T_{11} = T_{12} \quad q_f'' = q_{rp}'' + q_{cp}''$$

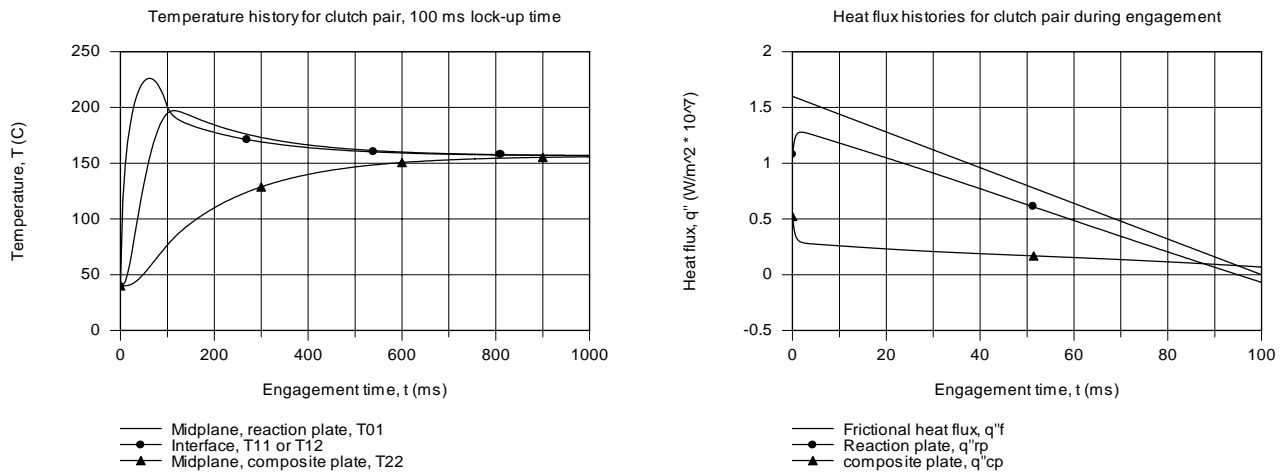

The frictional heat flux is represented by a *Lookup Table*, which along with the FDEs, are shown in the *IHT* code listed in Comment 2.

Continued (3)...

PROBLEM 5.118 (Cont.)

The temperature and heat flux histories are plotted below. The steady-state temperature was found as 156.5°C , which is in reasonable agreement with the energy balance result from part (a).

COMMENTS: (1) The temperature histories resulting from the FEHT and IHT based solutions are in agreement. The interface temperature peaks near 225°C after 75 ms, and begins dropping toward the steady-state condition. The mid-plane of the reaction plate peaks around 100 ms, nearly reaching 200°C . The temperature of the mid-plane of the composite plate increases slowly toward the steady-state condition.

(2) The calculated temperature-time histories for the clutch pair display similar features as expected from our initial sketches on T vs. t coordinates, part a. The maximum temperature for the composite is very high, subjecting the bonded frictional material to high thermal stresses as well as accelerating deterioration. For the reaction steel plate, the temperatures are moderate, but there is a significant gradient that could give rise to thermal stresses and hence, warping. Note that for the composite plate, the steel section is nearly isothermal and is less likely to experience warping.

(2) The *IHT* code representing the FDE for the 22 nodes and the frictional heat flux relation is shown below. Note use of the *Lookup Table* for representing the frictional heat flux vs. time boundary condition for nodes 11 and 12.

```
// Nodal equations, reaction plate (steel)
/* Node 01: surface node (w-orientation); transient conditions; e labeled 02. */
rhos * cps * der(T01,t) = fd_1d_sur_w(T01,T02,ks,qdot,deltax,Tinf01,h01,q''a01)

PROBLEM 5.119

KNOWN: Hamburger patties of thickness $2L = 10, 20$ and 30 mm, initially at a uniform temperature $T_i = 20^\circ\text{C}$, are grilled on both sides by a convection process characterized by $T_\infty = 100^\circ\text{C}$ and $h = 5000 \text{ W/m}^2\cdot\text{K}$.

FIND: (a) Determine the relationship between *time-to-doneness*, t_d , and patty thickness. Doneness criteria is 60°C at the center. Use *FEHT* and the *IHT Models/Transient Conduction/Plane Wall*. (b) Using the results from part (a), estimate the *time-to-doneness* if the initial temperature is 5°C rather than 20°C . Calculate values using the *IHT* model, and determine the relationship between time-to-doneness and initial temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, and (2) Constant properties are approximated as those of water at 300 K .

PROPERTIES: Table A-6, Water (300K), $\rho = 1000 \text{ kg/m}^3$, $c = 4179 \text{ J/kg}\cdot\text{K}$, $k = 0.613 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) To determine $T(0, t_d)$, the center point temperature at the *time-to-doneness* time, t_d , a one-dimensional shape as shown in the *FEHT* screen below is drawn, and the material properties, boundary conditions, and initial temperature are specified. With the *Run/Calculate* command, the early integration steps are made very fine to accommodate the large temperature-time changes occurring near $x = L$. Use the *Run | Continue* command (see *FEHT HELP*) for the second and subsequent steps of the integration. This sequence of *Start-(Step)-Stop* values was used: $0 (0.001) 0.1 (0.01) 1 (0.1) 120 (1.0) 840 \text{ s}$.

Continued

PROBLEM 5.119 (Cont.)

Using the *View/Temperature vs. Time* command, the temperature-time histories for the $x/L = 0$ (center), 0.5, and 1.0 (grill side) are plotted and shown below for the $2L = 10$ mm thick patty.

Using the *View/Temperatures* command, the time slider can be adjusted to read t_d , when the center point, $x = 0$, reaches 60°C . See the summary table below.

The *IHT ready-to-solve* model in *Models/Transient Conduction/Plane Wall* is based upon Eq. 5.40 and permits direct calculation of t_d when $T(0, t_d) = 60^\circ\text{C}$ for patty thickness $2L = 10, 20$ and 30 mm and initial temperatures of 20 and 5°C . The *IHT* code is provided in Comment 3, and the results are tabulated below.

	Solution method	Time-to-doneness, t (s)			T _i (C)
		Patty thickness, 2L (mm)			
		10	20	30	
	<i>FEHT</i>	66.2	264.5	591	20
	<i>IHT</i>	67.7	264.5	590.4	20
		80.2	312.2	699.1	5
	Eq. 5.40 (see Comment 4)	x	x		5
			x	x	20

Considering the *IHT* results for $T_i = 20^\circ\text{C}$, note that when the thickness is doubled from 10 to 20 mm, t_d is $(264.5/67.7=)$ 3.9 times larger. When the thickness is trebled, from 10 to 30 mm, t_d is $(590.4/67.7=)$ 8.7 times larger. We conclude that, t_d is nearly proportional to L^2 , rather than linearly proportional to thickness.

Continued

PROBLEM 5.119 (Cont.)

(b) The temperature span for the cooking process ranges from $T_\infty = 100$ to $T_i = 20$ or 5°C . The differences are $(100-20 =) 80$ or $(100-5 =) 95^\circ\text{C}$. If t_d is proportional to the overall temperature span, then we expect t_d for the cases with $T_i = 5^\circ\text{C}$ to be a factor of $(95/80 =) 1.19$ higher (approximately 20%) than with $T_i = 20^\circ\text{C}$. From the tabulated results above, for the thickness $2L = 10, 20$ and 30 mm, the t_d with $T_i = 5^\circ\text{C}$ are $(80.2/67.7 =) 1.18$, $(312 / 264.5 =) 1.18$, and $(699.1/590.4 =) 1.18$, respectively, higher than with $T_i = 20^\circ\text{C}$. We conclude that t_d is nearly proportional to the temperature span $(T_\infty - T_i)$.

COMMENTS: (1) The results from the *FEHT* and *IHT* calculations are in excellent agreement. For this analysis, the *FEHT* model is more convenient to use as it provides direct calculations of the time-to-doneness. The *FEHT* tool allows the user to watch the cooking process. Use the *View | Temperature Contours* command, click on the *from start-to-stop* button, and observe how color band changes represent the temperature distribution as a function of time.

(2) It is good practice to check software tool analyses against hand calculations. Besides providing experience with the basic equations, you can check whether the tool was used or functioned properly. Using the one-term series solution, Eq. 5.40:

$$\theta_o^* = \frac{T(0, t_d) - T_\infty}{T_i - T_\infty} = C_1 \exp(-\zeta^2 \text{Fo})$$

$$\text{Fo} = \alpha t_d / L^2 \quad C_1, \zeta = (\text{Bi}), \text{ Table 5.1}$$

T_i ($^\circ\text{C}$)	$2L$ (mm)	θ_o^*	Bi	C_1	ζ_1	Fo	t_d (s)
20	10	0.5000	24.47	1.2707	1.5068	0.4108	70.0
5	30	0.4211	73.41	1.2729	1.5471	0.4622	709

The results are slightly higher than those from the *IHT* model, which is based upon a multiple- rather than single-term series solution.

(3) The *IHT* code used to obtain the tabulated results is shown below. Note that $T_{\text{xt_trans}}$ is an intrinsic heat transfer function dropped into the *Workspace* from the *Models* window (see *IHT Help | Solver | Intrinsic Functions | Heat Transfer Functions*).

```
// Models | Transient Conduction | Plane Wall
/* Model: Plane wall of thickness 2L, initially with a uniform temperature T(x,0) = Ti, suddenly subjected
to convection conditions (Tinf,h). */
// The temperature distribution is
T_xt = T_xt_trans("Plane Wall",xstar,Fo,Bi,Ti,Tinf)           // Eq 5.40
// The dimensionless parameters are
xstar = x / L
Bi = h * L / k           // Eq 5.9
Fo = alpha * t / L^2     // Eq 5.33
alpha = k / (rho * cp)

// Input parameters
x = 0                    // Center point of meat
L = 0.005                // Meat half-thickness, m
//L = 0.010
//L = 0.015
T_xt = 60                // Doneness temperature requirement at center, x = 0; C
Ti = 20                  // Initial uniform temperature
//Ti = 5
rho = 1000               // Water properties at 300 K
cp = 4179
k = 0.613
h = 5000                 // Convection boundary conditions
Tinf = 100
```

PROBLEM 5.120

KNOWN: A process mixture at 200°C flows at a rate of 207 kg/min onto a 1-m wide conveyor belt traveling with a velocity of 36 m/min. The underside of the belt is cooled by a water spray.

FIND: The surface temperature of the mixture at the end of the conveyor belt, $T_{e,s}$, using (a) *IHT* for writing and solving the FDEs, and (b) *FEHT*. Validate your numerical codes against an appropriate analytical method of solution.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x -direction at any z -location, (2) Negligible heat transfer from mixture upper surface to ambient air, and (3) Constant properties.

PROPERTIES: Process mixture (m), $\rho_m = 960 \text{ kg/m}^3$, $c_m = 1700 \text{ J/kg}\cdot\text{K}$, and $k_m = 1.5 \text{ W/m}\cdot\text{K}$; Conveyor belt (b), $\rho_b = 8000 \text{ kg/m}^3$, $c_b = 460 \text{ J/kg}\cdot\text{K}$, and $k_b = 15 \text{ W/m}\cdot\text{K}$.

ANALYSIS: From the conservation of mass requirement, the thickness of the mixture on the conveyor belt can be determined.

$$\dot{m} = \rho_m A_c V \quad \text{where} \quad A_c = W L_m$$

$$207 \text{ kg/min} \times 1 \text{ min/60 s} = 960 \text{ kg/m}^3 \times 1 \text{ m} \times L_m \times 36 \text{ m/min} \times 1 \text{ min/60 s}$$

$$L_m = 0.0060 \text{ m} = 6 \text{ mm}$$

The time that the mixture is in contact with the steel conveyor belt, referred to as the residence time, is

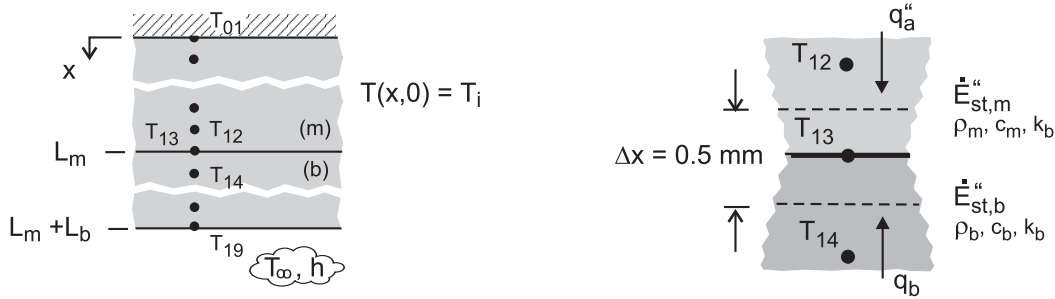

$$t_{\text{res}} = L_c / V = 30 \text{ m} / (36 \text{ m/min} \times 1 \text{ min/60 s}) = 50 \text{ s}$$

The composite system comprised of the belt, $L_b = 3 \text{ mm}$, and mixture, $L_m = 6 \text{ mm}$, as represented in the schematic above, is initially at a uniform temperature $T(x,0) = T_i = 200^\circ\text{C}$ while at location $z = 0$, and suddenly is exposed to convection cooling (T_∞, h). We will calculate the mixture upper surface temperature after 50 s, $T(0, t_{\text{res}}) = T_{e,s}$.

(a) The nodal arrangement for the composite system is shown in the schematic below. The *IHT* model builder *Tools/Finite-Difference Equations/Transient* can be used to obtain the FDEs for nodes 01-12 and 14-19.

Continued

PROBLEM 5.120 (Cont.)

For the mixture-belt interface node 13, the FDE for the implicit method is derived from an energy balance on the control volume about the node as shown above.

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' = \dot{E}_{\text{st}}''$$

$$q_a'' + q_b'' = \dot{E}_{\text{st},m}'' + \dot{E}_{\text{st},b}''$$

$$k_m \frac{T_{12}^{p+1} - T_{13}^{p+1}}{\Delta x} + k_b \frac{T_{14}^{p+1} - T_{13}^{p+1}}{\Delta x} = (\rho_m c_m + \rho_b c_b) (\Delta x / 2) \frac{T_{13}^{p+1} - T_{13}^p}{\Delta t}$$

IHT code representing selected FDEs, nodes 01, 02, 13 and 19, is shown in Comment 4 below ($\Delta x = 0.5$ mm, $\Delta t = 0.1$ s). Note how the FDE for node 13 derived above is written in the *Workspace*. From the analysis, find

$$T_{e,s} = T(0, 50\text{s}) = 54.8^\circ\text{C}$$

<

(b) Using *FEHT*, the composite system is drawn and the material properties, boundary conditions, and initial temperature are specified. The screen representing the system is shown below in Comment 5 with annotations on key features. From the analysis, find

$$T_{e,s} = T(0, 50\text{s}) = 54.7^\circ\text{C}$$

<

COMMENTS: (1) Both numerical methods, *IHT* and *FEHT*, yielded the same result, 55°C . For the safety of plant personnel working in the area of the conveyor exit, the mixture exit temperature should be lower, like 43°C .

(2) By giving both regions of the composite the same properties, the analytical solution for the plane wall with convection, Section 5.5, Eq. 5.40, can be used to validate the *IHT* and *FEHT* codes. Using the *IHT Models/Transient Conduction/Plane Wall* for a 9-mm thickness wall with mixture thermophysical properties, we calculated the temperatures after 50 s for three locations: $T(0, 50\text{s}) = 91.4^\circ\text{C}$; $T(6\text{ mm}, 50\text{s}) = 63.6^\circ\text{C}$; and $T(3\text{ mm}, 50\text{s}) = 91.4^\circ\text{C}$. The results from the *IHT* and *FEHT* codes agreed exactly.

(3) In view of the high heat removal rate on the belt lower surface, it is reasonable to assume that negligible heat loss is occurring by convection on the top surface of the mixture.

Continued

PROBLEM 5.120 (Cont.)

(4) The *IHT* code representing selected FDEs, nodes 01, 02, 13 and 19, is shown below. The FDE for node 13 was derived from an energy balance, while the others are written from the *Tools* pad.

```
// Finite difference equations from Tools, Nodes 01 -12 (mixture) and 14-19 (belt)
/* Node 01: surface node (w-orientation); transient conditions; e labeled 02. */
rho_m * cm * der(T01,t) = fd_1d_sur_w(T01,T02,km,qdot,deltax,Tinf01,h01,q"a01)
q"a01 = 0      // Applied heat flux, W/m^2; zero flux shown
qdot = 0
Tinf01 = 20    // Arbitrary value
h01 = 1e-6    // Causes boundary to behave as adiabatic

/* Node 02: interior node; e and w labeled 03 and 01. */
rho_m*cm*der(T02,t) = fd_1d_int(T02,T03,T01,km,qdot,deltax)

/* Node 19: surface node (e-orientation); transient conditions; w labeled 18. */
rho_b * cb * der(T19,t) = fd_1d_sur_e(T19,T18,kb,qdot,deltax,Tinf19,h19,q"a19)
q"a19 = 0      // Applied heat flux, W/m^2; zero flux shown
Tinf19 = 30
h19 = 3000

// Finite-difference equation from energy balance on CV, Node 13
km*(T12 - T13)/deltax + kb*(T14 - T13)/deltax = (rho_m*cm + rho_b*cb) *(deltax/2)*der(T13,t)
```

(5) The screen from the *FEHT* analysis is shown below. It is important to use small time steps in the integration at early times. Use the *View/Temperatures* command to find the temperature of the mixture surface at $t_{res} = 50$ s.

PROBLEM 5.121

KNOWN: Thin, circular-disc subjected to induction heating causing a uniform heat generation in a prescribed region; upper surface exposed to convection process.

FIND: (a) Transient finite-difference equation for a node in the region subjected to induction heating, (b) Sketch the steady-state temperature distribution on T-r coordinates; identify important features.

SCHEMATIC:

ASSUMPTIONS: (1) Thickness $w \ll r_0$, such that conduction is one-dimensional in r-direction, (2) In prescribed region, \dot{q} is uniform, (3) Bottom surface of disc is insulated, (4) Constant properties.

ANALYSIS: (a) Consider the nodal point arrangement for the region subjected to induction heating. The size of the control volume is $V = 2\pi r_m \cdot \Delta r \cdot w$. The energy conservation requirement for the node m has the form

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}$$

with $q_a + q_b + q_{conv} + \dot{q}V = \dot{E}_{st}$.

Recognizing that q_a and q_b are conduction terms and q_{conv} is the convection process,

$$k \left[2\pi \left[r_m - \frac{\Delta r}{2} \right] w \right] \frac{T_{m-1}^p - T_m^p}{\Delta r} + k \left[2\pi \left[r_m + \frac{\Delta r}{2} \right] w \right] \frac{T_{m+1}^p - T_m^p}{\Delta r} + h \left[2\pi r_m \cdot \Delta r \right] (T_\infty - T_m^p) + \dot{q} \left[2\pi r_m \cdot \Delta r \cdot w \right] = \rho c_p \left[2\pi r_m \cdot \Delta r \cdot w \right] \frac{T_m^{p+1} - T_m^p}{\Delta t}$$

Upon regrouping, the finite-difference equation has the form,

$$T_m^{p+1} = Fo \left[\left[1 - \frac{\Delta r}{2r_m} \right] T_{m-1}^p + \left[1 + \frac{\Delta r}{2r_m} \right] T_{m+1}^p + Bi \left[\frac{\Delta r}{w} \right] T_\infty + \frac{\dot{q}\Delta r^2}{k} \right] + \left[1 - 2Fo - Bi \cdot Fo \left[\frac{\Delta r}{w} \right] \right] T_m^p \quad <$$

where $Fo = \alpha \Delta t / \Delta r^2$ $Bi = h \Delta r / k$.

(b) The steady-state temperature distribution has these features:

1. Zero gradient at $r = 0, r_0$
2. No discontinuity at r_1, r_2
3. T_{max} occurs in region $r_1 < r < r_2$

Note also, distribution will not be linear anywhere;

distribution is not parabolic in $r_1 < r < r_2$ region.

PROBLEM 5.122

KNOWN: An electrical cable experiencing uniform volumetric generation; the lower half is well insulated while the upper half experiences convection.

FIND: (a) Explicit, finite-difference equations for an interior node (m,n), the center node ($0,0$), and an outer surface node (M,n) for the convective and insulated boundaries, and (b) Stability criterion for each FDE; identify the most restrictive criterion.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional (r,ϕ), transient conduction, (2) Constant properties, (3) Uniform \dot{q} .

ANALYSIS: The explicit, finite-difference equations may be obtained by applying energy balances to appropriate control volumes about the node of interest. Note the coordinate system defined above where $(r,\phi) \rightarrow (m\Delta r, n\Delta\phi)$. The stability criterion is determined from the coefficient associated with the node of interest.

Interior Node (m,n). The control volume for an interior node is

$$V = r_m \Delta\phi \cdot \Delta r \cdot \ell$$

(with $r_m = m\Delta r$, $\ell = 1$) where ℓ is the length normal to the page. The conservation of energy requirement is

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = \dot{E}_{\text{st}}$$

$$(q_1 + q_2)_r + (q_3 + q_4)_\theta + \dot{q}V = \rho c V \frac{T_{m,n}^{p+1} - T_{m,n}^p}{\Delta t}$$

$$k \cdot \left[m - \frac{1}{2} \right] \Delta r \cdot \Delta\phi \cdot \frac{T_{m-1,n}^p - T_{m,n}^p}{\Delta r} + k \cdot \left[m + \frac{1}{2} \right] \Delta r \cdot \Delta\phi \cdot \frac{T_{m+1,n}^p - T_{m,n}^p}{\Delta r} + k \cdot \Delta r \cdot \frac{T_{m,n+1}^p - T_{m,n}^p}{(m\Delta r)\Delta\phi}$$

$$+ k \cdot \Delta r \cdot \frac{T_{m,n-1}^p - T_{m,n}^p}{(m\Delta r)\Delta\phi} + \dot{q}(m\Delta r \cdot \Delta\phi) \cdot \Delta r = \rho c (m\Delta r \cdot \Delta\phi) \cdot \Delta r \cdot \frac{T_{m,n}^{p+1} - T_{m,n}^p}{\Delta t} \quad (1)$$

Define the Fourier number as

$$Fo = \frac{k}{\rho c} \cdot \frac{\Delta t}{\Delta r^2} = \frac{\alpha \Delta t}{\Delta r^2} \quad (2)$$

and then regroup the terms of Eq. (1) to obtain the FDE,

$$T_{m,n}^{p+1} = Fo \left\{ \frac{m-1/2}{m} T_{m-1,n}^p + \frac{m+1/2}{m} T_{m+1,n}^p + \frac{1}{(m\Delta\phi)^2} \left(T_{m,n+1}^p + T_{m,n-1}^p \right) + \frac{\dot{q}}{k} \Delta r^2 \right\}$$

$$+ \left\{ -Fo \left[2 + \frac{2}{(m\Delta\phi)^2} \right] + 1 \right\} T_{m,n}^p. \quad (3) <$$

Continued

PROBLEM 5.122 (Cont.)

The stability criterion requires that the last term on the right-hand side in braces be positive. That is, the coefficient of $T_{m,n}^p$ must be positive and the stability criterion is

$$Fo \leq 1/2 \left[1 + 1/(m\Delta\phi)^2 \right] \quad (4)$$

Note that, for $m \gg 1/2$ and $(m\Delta\phi)^2 \gg 1$, the FDE takes the form of a 1-D cartesian system. *Center Node (0,0)*. For the control volume,

$V = \pi(\Delta r/2)^2 \cdot 1$. The energy balance is

$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_g = \dot{E}'_{st}$ where $\dot{E}'_{in} = \sum q'_n$.

$$\begin{aligned} \sum_{n=0}^N k \cdot \left[\frac{\Delta r}{2} \Delta\phi \right] \cdot \frac{T_{1,n}^p - T_0^p}{\Delta r} + \dot{q} \pi \left[\frac{\Delta r}{2} \right]^2 \\ = \rho c \cdot \pi \left[\frac{\Delta r}{2} \right]^2 \frac{T_0^{p+1} - T_0^p}{\Delta t} \end{aligned} \quad (5)$$

where $N = (2\pi/\Delta\phi) - 1$, the total number of q_n . Using the definition of Fo , find

$$T_0^{p+1} = 4Fo \left\{ \frac{1}{N+1} \sum_{n=0}^N T_{1,n}^p + \frac{\dot{q}}{4k} \Delta r^2 \right\} + (1 - 4Fo) T_0^p. \quad (7)$$

By inspection, the stability criterion is $Fo \leq 1/4$.

Surface Nodes (M,n). The control volume

for the surface node is $V = (M - 1/4)\Delta r \Delta\phi \cdot \Delta r/2 \cdot 1$.

From the energy balance,

$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_g = (q'_1 + q'_2)_r + (q'_3 + q'_4)_\phi + \dot{q}V = \dot{E}'_{st}$

$$\begin{aligned} k \cdot (M - 1/2) \Delta r \cdot \Delta\phi \cdot \frac{T_{M-1,n}^p - T_{M,n}^p}{\Delta r} + h(M\Delta r \cdot \Delta\phi) (T_\infty - T_{M,n}^p) + k \cdot \frac{\Delta r}{2} \cdot \frac{T_{M,n+1}^p - T_{M,n}^p}{(M\Delta r) \Delta\phi} \\ + k \cdot \frac{\Delta r}{2} \cdot \frac{T_{M,n-1}^p - T_{M,n}^p}{(M\Delta r) \Delta\phi} + \dot{q} \left[(M - 1/4) \Delta r \cdot \Delta\phi \cdot \frac{\Delta r}{2} \right] = \rho c \left[(M - 1/4) \Delta r \cdot \Delta\phi \cdot \frac{\Delta r}{2} \right] \frac{T_{M,n}^{p+1} - T_{M,n}^p}{\Delta t} \end{aligned}$$

Regrouping and using the definitions for $Fo = \alpha\Delta t/\Delta r^2$ and $Bi = h\Delta r/k$,

$$\begin{aligned} T_{m,n}^{p+1} = Fo \left\{ 2 \frac{M-1/2}{M-1/4} T_{M-1,n}^p + \frac{1}{(M-1/4)M(\Delta\phi)^2} (T_{M,n+1}^p - T_{M,n-1}^p) + 2Bi \cdot T_\infty + \frac{\dot{q}}{k} \Delta r^2 \right\} \\ + \left\{ 1 - 2Fo \left[\frac{M-1/2}{M-1/4} + Bi \cdot \frac{M}{M-1/4} + \frac{1}{(M-1/4)M(\Delta\phi)^2} \right] \right\} T_{M,n}^p. \quad (8) \end{aligned}$$

$$\text{The stability criterion is} \quad Fo \leq \frac{1}{2} \left[\frac{M-1/2}{M-1/4} + Bi \frac{M}{M-1/4} + \frac{1}{(M-1/4)M(\Delta\phi)^2} \right]. \quad (9)$$

To determine which stability criterion is most restrictive, compare Eqs. (4), (7) and (9). The most restrictive (lowest Fo) has the largest denominator. For small values of m , it is not evident whether Eq. (7) is more restrictive than Eq. (4); Eq. (4) depends upon magnitude of $\Delta\phi$. Likewise, it is not clear whether Eq. (9) will be more or less restrictive than Eq. (7). Numerical values must be substituted.

PROBLEM 5.123

KNOWN: Initial temperature distribution in two bars that are to be soldered together; interface contact resistance.

FIND: (a) Explicit FDE for $T_{4,2}$ in terms of Fo and $Bi = \Delta x/k R''_{t,c}$; stability criterion, (b) $T_{4,2}$ one time step after contact is made if $Fo = 0.01$ and value of Δt ; whether the stability criterion is satisfied.

SCHEMATIC:

PROPERTIES: Table A-1, Steel, AISI 1010 (1000K): $k = 31.3 \text{ W/m}\cdot\text{K}$, $c = 1168 \text{ J/kg}\cdot\text{K}$, $\rho = 7832 \text{ kg/m}^3$.

ASSUMPTIONS: (1) Two-dimensional transient conduction, (2) Constant properties, (3) Interfacial solder layer has negligible thickness.

ANALYSIS: (a) From an energy balance on the control volume $V = (\Delta x/2) \cdot \Delta y \cdot 1$.

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = \dot{E}_{\text{st}}$$

$$q_a + q_b + q_c + q_d = \rho c V \frac{T_{4,2}^{p+1} - T_{4,2}^p}{\Delta t}.$$

Note that $q_a = (\Delta T/R''_{t,c}) A_c$ while the remaining q_i are conduction terms,

$$\begin{aligned} \frac{1}{R''_{t,c}} (T_{3,2}^p - T_{4,2}^p) \Delta y + k (\Delta x/2) \frac{(T_{4,3}^p - T_{4,2}^p)}{\Delta y} + k (\Delta y) \frac{(T_{5,2}^p - T_{4,2}^p)}{\Delta x} \\ + k (\Delta x/2) \frac{(T_{4,1}^p - T_{4,2}^p)}{\Delta y} = \rho c [(\Delta x/2) \cdot \Delta y] \frac{T_{4,2}^{p+1} - T_{4,2}^p}{\Delta t}. \end{aligned}$$

Defining $Fo \equiv (k/\rho c) \Delta t / \Delta x^2$ and $Bi_c \equiv \Delta y / R''_{t,c} k$, regroup to obtain

$$T_{4,2}^{p+1} = Fo (T_{4,3}^p + 2T_{5,2}^p + T_{4,1}^p + 2Bi_c T_{3,2}^p) + (1 - 4Fo - 2FoBi_c) T_{4,2}^p. \quad <$$

The stability criterion requires the coefficient of the $T_{4,2}^p$ term be zero or positive,

$$(1 - 4Fo - 2FoBi_c) \geq 0 \quad \text{or} \quad Fo \leq 1/(4 + 2Bi_c) \quad <$$

(b) For $Fo = 0.01$ and $Bi = 0.020\text{m} / (2 \times 10^{-5} \text{m}^2 \cdot \text{K/W} \times 31.3 \text{W/m}\cdot\text{K}) = 31.95$,

$$T_{4,2}^{p+1} = 0.01(1000 + 2 \times 900 + 1000 + 2 \times 31.95 \times 700) \text{K} + (1 - 4 \times 0.01 - 2 \times 0.01 \times 31.95) 1000 \text{K}$$

$$T_{4,2}^{p+1} = 485.30 \text{K} + 321.00 \text{K} = 806.3 \text{K}. \quad <$$

With $Fo = 0.01$, the time step is

$$\Delta t = Fo \Delta x^2 (\rho c/k) = 0.01 (0.020 \text{m})^2 \left(7832 \text{kg/m}^3 \times 1168 \text{J/kg}\cdot\text{K} / 31.3 \text{W/m}\cdot\text{K} \right) = 1.17 \text{s}. \quad <$$

With $Bi = 31.95$ and $Fo = 0.01$, the stability criterion, $Fo \leq 0.015$, is satisfied. <

PROBLEM 5.124

KNOWN: Stainless steel cylinder, 80-mm diameter by 60-mm length, initially at 600 K, suddenly quenched in an oil bath at 300 K with $h = 500 \text{ W/m}^2 \cdot \text{K}$. Use the ready-to-solve model in the *Examples* menu of *FEHT* to obtain the following solutions.

FIND: (a) Calculate the temperatures $T(r, x, t)$ after 3 min: at the cylinder center, $T(0, 0, 3 \text{ min})$, at the center of a circular face, $T(0, L, 3 \text{ min})$, and at the midheight of the side, $T(r_o, 0, 3 \text{ min})$; compare your results with those in the example; (b) Calculate and plot temperature histories at the cylinder center, $T(0, 0, t)$, the mid-height of the side, $T(r_o, 0, t)$, for $0 \leq t \leq 10 \text{ min}$; use the *View/Temperature vs. Time* command; comment on the gradients and what effect they might have on phase transformations and thermal stresses; (c) Using the results for the total integration time of 10 min, use the *View/Temperature Contours* command; describe the major features of the cooling process shown in this display; create and display a 10-isotherm temperature distribution for $t = 3 \text{ min}$; and (d) For the locations of part (a), calculate the temperatures after 3 min if the convection coefficient is doubled ($h = 1000 \text{ W/m}^2 \cdot \text{K}$); for these two conditions, determine how long the cylinder needs to remain in the oil bath to achieve a safe-to touch surface temperature of 316 K. Tabulate and comment on the results of your analysis.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction in r - and x -coordinates, (2) Constant properties.

PROPERTIES: Stainless steel: $\rho = 7900 \text{ kg/m}^3$, $c = 526 \text{ J/kg} \cdot \text{K}$, $k = 17.4 \text{ W/m} \cdot \text{K}$.

ANALYSIS: (a) The *FEHT ready-to-solve* model is accessed through the *Examples* menu and the annotated *Input* page is shown below. The following steps were used to obtain the solution: (1) Use the *Draw/Reduce Mesh* command three times to create the 512-element mesh; (2) In *Run*, click on *Check*, (3) In *Run*, press *Calculate* and hit *OK* to initiate the solver; and (4) Go to the *View* menu, select *Tabular Output* and read the nodal temperatures 4, 1, and 3 at $t = t_o = 180 \text{ s}$. The tabulated results below include those from the n -term series solution used in the *IHT* software.

Continued

PROBLEM 5.124 (Cont.)

(r, x, t_0)	FEHT node	$T(r, x, t_0)$ (K) <i>FEHT</i>	$T(r, x, t_0)$ (K) 1-term series	$T(r, x, t_0)$ (K) n-term series
$0, 0, t_0$	4	402.7	405	402.7
$0, L, t_0$	1	368.7	372	370.5
$r_o, 0, t_0$	3	362.5	365	362.4

The *FEHT* results are in excellent agreement with the *IHT* n-term series solutions for the $x = 0$ plane nodes (4,3), except for the $x = L$ plane node (1).

(b) Using the *View Temperature vs. Time* command, the temperature histories for nodes 4, 1, and 3 are plotted in the graph shown below. There is very small temperature difference between the locations on the surface, (node 1; $0, L$) and (node 3; $r_o, 0$). But, the temperature difference between these surface locations and the cylinder center (node 4; $0, 0$) is large at early times. Such differences wherein locations cool at considerably different rates could cause variations in microstructure and hence, mechanical properties, as well as induce thermal stresses.

Continued

PROBLEM 5.124 (Cont.)

(c) Use the *View|Temperature Contours* command with the shaded band option for the isotherm contours. Selecting the *From Start to Stop* time option, see the display of the contours as the cylinder cools during the quench process. The “movie” shows that cooling initiates at the corner (r_o, L, t) and the isotherms quickly become circular and travel toward the center $(0, 0, t)$. The 10-isotherm distribution for $t = 3$ min is shown below.

(d) Using the *FEHT* model with convection coefficients of 500 and 1000 $\text{W/m}^2 \cdot \text{K}$, the temperatures at $t = t_o = 180$ s for the three locations of part (a) are tabulated below.

	$h = 500 \text{ W/m}^2 \cdot \text{K}$	$h = 1000 \text{ W/m}^2 \cdot \text{K}$
$T(0, 0, t_o), \text{ K}$	402.7	352.8
$T(0, L, t_o), \text{ K}$	368.7	325.8
$T(r_o, 0, t_o), \text{ K}$	362.5	322.1

Note that the effect of doubling the convection coefficient is to reduce the temperature at these locations by about 40°C . The time the cylinder needs to remain in the oil bath to achieve the *safe-to-touch* surface temperature of 316 K can be determined by examining the temperature history of the location (node1; 0, L). For the two convection conditions, the results are tabulated below. Doubling the coefficient reduces the cooling process time by 40 %.

$T(0, L, t_o)$	$h (\text{W/m}^2 \cdot \text{K})$	$t_o (\text{s})$
316	500	370
316	1000	219

PROBLEM 5.125

KNOWN: Flue of square cross-section, initially at a uniform temperature is suddenly exposed to hot flue gases. See Problem 4.55.

FIND: Temperature distribution in the wall 5, 10, 50 and 100 hours after introduction of gases using the *implicit* finite-difference method.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional transient conduction, (2) Constant properties.

PROPERTIES: Flue (given): $k = 0.85 \text{ W/m}\cdot\text{K}$, $\alpha = 5.5 \times 10^{-7} \text{ m}^2/\text{s}$.

ANALYSIS: The network representing the flue cross-sectional area is shown with $\Delta x = \Delta y = 50 \text{ mm}$. Initially all nodes are at $T_i = 25^\circ\text{C}$ when suddenly the interior and exterior surfaces are exposed to convection processes, $(T_{\infty,i}, h_i)$ and $(T_{\infty,o}, h_o)$, respectively. Referring to the network above, note that there are four types of nodes: interior (02, 03, 06, 07, 10, 11, 14, 15, 17, 18, 20); plane surfaces with convection (interior – 01, 05, 09); interior corner with convection (13), plane surfaces with convection (exterior – 04, 08, 12, 16, 19, 21); and, exterior corner with convection. The system of finite-difference equations representing the network is obtained using *IHT Tools Finite-difference equations Two-dimensional Transient*. The *IHT* code is shown in Comment 2 and the results for $t = 5, 10, 50$ and 100 hour are tabulated below.

$$\text{Node 17} \quad (1 + 4\text{Fo})T_{17}^{p+1} - \text{Fo} \left(T_{18}^{p+1} + T_{14}^{p+1} + T_{18}^{p+1} + T_{14}^{p+1} \right) = T_{17}^p$$

$$\text{Node 13} \quad \left[1 + 4\text{Fo} \left[1 + \frac{1}{3} \text{Bi}_i \right] \right] T_{13}^{p+1} - \frac{2}{3} \text{Fo} \left(2T_{14}^{p+1} + T_9 + 2T_{14}^{p+1} + T_9^{p+1} \right) = T_{13}^p + \frac{4}{3} \text{Bi}_i \cdot \text{Fo} \cdot T_{\infty,i}$$

$$\text{Node 12} \quad (1 + 2\text{Fo}(2 + \text{Bi}_o))T_{12}^{p+1} - \text{Fo} \left(2T_{11}^{p+1} + T_{16}^{p+1} + T_8^{p+1} \right) = T_{12}^p + 2\text{Bi}_o \cdot \text{Fo} \cdot T_{\infty,o}$$

$$\text{Node 22} \quad (1 + 4\text{Fo}(1 + \text{Bi}_o))T_{22}^{p+1} - 2\text{Fo} \left(T_{21}^{p+1} + T_{21}^{p+1} \right) = T_{22}^p + 4\text{Bi}_o \cdot \text{Fo} \cdot T_{\infty,o}$$

Numerical values for the relevant parameters are:

$$\text{Fo} = \frac{\alpha \Delta t}{\Delta x^2} = \frac{5.5 \times 10^{-7} \text{ m}^2/\text{s} \times 3600 \text{ s}}{(0.050 \text{ m})^2} = 7.92000$$

$$\text{Bi}_o = \frac{h_o \Delta x}{k} = \frac{5 \text{ W/m}^2 \cdot \text{K} \times 0.050 \text{ m}}{0.85 \text{ W/m}\cdot\text{K}} = 0.29412$$

$$\text{Bi}_i = \frac{h_i \Delta x}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 0.050 \text{ m}}{0.85 \text{ W/m}\cdot\text{K}} = 5.88235$$

The system of FDEs can be represented in matrix notation, $[A][T] = [C]$. The coefficient matrix $[A]$ and terms for the right-hand side matrix $[C]$ are given on the following page.

T21	25	72.43	106.70	120.60	120.60
T22	25	59.47	87.37	98.89	98.89

COMMENTS: (1) Note that the steady-state condition is reached by $t = 5$ hours; this can be seen by comparing the distributions for $t = 50$ and 100 hours. Within 10 hours, the flue is within a few degrees of the steady-state condition.

```

(3) The results for $t = 50$ hour, representing the steady-state condition, are shown below, arranged according to the coordinate system.

x/y (mm)	T _{mn} (C)						
	0	50	100	150	200	250	300
0	181.60	179.50	172.70	160.20	141.80	120.60	98.89
50	229.80	227.30	219.00	202.90	177.50	149.00	
100	282.90	280.80	273.20	172.70	216.20		
150	340.20	339.90	338.20	327.30			

In Problem 4.55, the temperature distribution was determined using the FDEs written for steady-state conditions, but with a finer network, $\Delta x = \Delta y = 25$ mm. By comparison, the results for the coarser network are slightly higher, within a fraction of 1°C , along the mid-section of the flue, but notably higher in the vicinity of inner corner. (For example, node 13 is 2.6°C higher with the coarser mesh.)

PROBLEM 5.126

KNOWN: Electrical heating elements embedded in a ceramic plate as described in Problem 4.73; initially plate is at a uniform temperature and suddenly heaters are energized.

FIND: Time required for the difference between the surface and initial temperatures to reach 95% of the difference for steady-state conditions using the implicit, finite-difference method.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Constant properties, (3) No internal generation except for Node 7, (4) Heating element approximates a line source; wire diameter is negligible.

ANALYSIS: The grid for the symmetry element above consists of 12 nodes. Nodes 1-3 are points on a surface experiencing convection; nodes 4-12 are interior nodes; node 7 is a special case with internal generation and because of symmetry, $q'_{ht} = 25 \text{ W/m}$. Their finite-difference equations are derived as follows

Surface Node 2. From an energy balance on the prescribed control volume with $\Delta x/\Delta y = 3$,

$$\begin{aligned} \dot{E}_{in} = \dot{E}_{st} = q'_a + q'_b + q'_c + q'_d = \rho c V \frac{T_2^{p+1} - T_2^p}{\Delta t} \\ k \frac{\Delta y}{2} \frac{T_1^{p+1} - T_2^{p+1}}{\Delta x} + h \Delta x (T_\infty - T_2^{p+1}) \\ + k \frac{\Delta y}{2} \frac{T_3^{p+1} - T_2^{p+1}}{\Delta x} + k \Delta x \frac{T_5^{p+1} - T_2^{p+1}}{\Delta y} = \rho c \left[\Delta x \frac{\Delta y}{2} \right] \frac{T_2^{p+1} - T_2^p}{\Delta t} \end{aligned}$$

Continued

PROBLEM 5.126 (Cont.)

Divide by k , use the following definitions, and regroup to obtain the finite-difference equations.

$$N \equiv h\Delta x/k = 100 \text{ W/m}^2 \cdot \text{K} \times 0.006\text{m}/2 \text{ W/m} \cdot \text{K} = 0.3000 \quad (1)$$

$$Fo \equiv (k/\rho c) \Delta t/\Delta x \cdot \Delta y = \alpha \Delta t/\Delta x \cdot \Delta y = 1.5 \times 10^{-6} \text{ m}^2/\text{s} \times 1\text{s}/(0.006 \times 0.002) \text{ m}^2 = 0.1250 \quad (2)$$

$$\begin{aligned} \frac{1}{2} \left[\frac{\Delta y}{\Delta x} \right] (T_1^{p+1} - T_2^{p+1}) + N(T_\infty - T_2^{p+1}) + \frac{1}{2} \left[\frac{\Delta y}{\Delta x} \right] (T_3^{p+1} - T_2^{p+1}) \\ + \left[\frac{\Delta x}{\Delta y} \right] (T_5^{p+1} - T_2^{p+1}) = \frac{1}{2Fo} (T_2^{p+1} - T_2^p) \\ \frac{1}{2} \left[\frac{\Delta y}{\Delta x} \right] T_1^{p+1} - \left[\left[\frac{\Delta x}{\Delta y} \right] + N + \left[\frac{\Delta y}{\Delta x} \right] + \frac{1}{2Fo} \right] T_2^{p+1} + \frac{1}{2} \left[\frac{\Delta x}{\Delta y} \right] T_3^{p+1} \\ + \left[\frac{\Delta x}{\Delta y} \right] T_5^{p+1} = -NT_\infty - \frac{1}{2Fo} T_2^p. \end{aligned} \quad (3)$$

Substituting numerical values for Fo and N , and using $T_\infty = 30^\circ\text{C}$ and $\Delta x/\Delta y = 3$, find $0.16667T_1^{p+1} - 7.63333T_2^{p+1} + 0.16667T_3^{p+1} + 3.00000T_5^{p+1} = 9.0000 - 4.0000T_2^p$. (4)

By inspection and use of Eq. (3), the FDEs for Nodes 1 and 3 can be inferred.

Interior Node 7. From an energy balance on the prescribed control volume with $\Delta x/\Delta y = 3$,

$$\dot{E}'_{in} + \dot{E}'_g = \dot{E}'_{st}$$

where $\dot{E}'_g = 2q'_{ht}$ and \dot{E}'_{in} represents the conduction terms $-q'_a + q'_b + q'_c + q'_d$,

$$\begin{aligned} k\Delta y \frac{T_8^{p+1} - T_7^{p+1}}{\Delta x} + k\Delta x \frac{T_4^{p+1} - T_7^{p+1}}{\Delta y} + k\Delta y \frac{T_8^{p+1} - T_7^{p+1}}{\Delta x} \\ + k\Delta x \frac{T_{10}^{p+1} - T_7^{p+1}}{\Delta y} + 2q'_{ht} = \rho c (\Delta x \cdot \Delta y) \frac{T_7^{p+1} - T_7^p}{\Delta t}. \end{aligned}$$

Using the definition of Fo , Eq. (2), and regrouping, find

$$\begin{aligned} \frac{1}{2} \left[\frac{\Delta x}{\Delta y} \right] T_4^{p+1} - \left[\left[\frac{\Delta x}{\Delta y} \right] + \left[\frac{\Delta y}{\Delta x} \right] + \frac{1}{2Fo} \right] T_7^{p+1} \\ + \left[\frac{\Delta y}{\Delta x} \right] T_8^{p+1} + \frac{1}{2} \left[\frac{\Delta x}{\Delta y} \right] T_{10}^{p+1} = -\frac{q'_{ht}}{k} - \frac{1}{2Fo} T_7^p \end{aligned} \quad (5)$$

$$1.50000T_4^{p+1} - 7.33333T_7^{p+1} + 0.33333T_8^{p+1} + 1.50000T_{10}^{p+1} = -12.5000 - 4.0000T_7^p. \quad (6)$$

PROBLEM 5.126 (Cont.)

Recognizing the form of Eq. (5), it is a simple matter to infer the FDE for the remaining interior points for which $\dot{q}_{ht} = 0$. In matrix notation $[A][T] = [C]$, the coefficient matrix $[A]$ and RHS matrix $[C]$ are:

THE COEFFICIENT MATRIX, [A]												[C]

Recall that the problem asks for the time required to reach 95% of the difference for steady-state conditions. This provides information on approximately how long it takes for the plate to come to a steady operating condition. If you worked Problem 4.73, you know the steady-state temperature distribution. Then you can proceed to find the

T_m^P values with increasing time until the *first* node reaches

the required limit. We should not expect the nodes to reach their limit at the same time.

Not knowing the steady-state temperature distribution, use the implicit FDE in matrix form above to step through time $\rightarrow \infty$ to the steady-state solution; that is, proceed to $p \rightarrow$

10,20...100 until the solution matrix $[T]$ does not change. The results of the analysis are tabulated below. Column 1 labeled $T_m(\infty)$ is the steady-state distribution. Column 2,

$T_m(95\%)$, is the 95% limit being sought as per the graph directly above. The third column is the temperature distribution at $t = t_0 = 248s$, $T_m(248s)$; at this elapsed time, Node 1 has reached its limit. Can you explain why this node was the first to reach this limit? Which nodes will be the last to reach their limits?

$T_m(\infty)$	$T_m(95\%)$	$T_m(248s)$

PROBLEM 5.127

KNOWN: Nodal network and operating conditions for a water-cooled plate.

FIND: Transient temperature response.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction.

ANALYSIS: The energy balance method must be applied to each nodal region. Grouping similar regions, the following results are obtained.

Nodes 1 and 5:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2}\right) T_1^{p+1} - \frac{2\alpha\Delta t}{\Delta x^2} T_2^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_6^{p+1} = T_1^p$$

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2}\right) T_5^{p+1} - \frac{2\alpha\Delta t}{\Delta x^2} T_4^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_{10}^{p+1} = T_5^p$$

Nodes 2, 3, 4:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2}\right) T_{m,n}^{p+1} - \frac{\alpha\Delta t}{\Delta x^2} T_{m-1,n}^{p+1} - \frac{\alpha\Delta t}{\Delta x^2} T_{m+1,n}^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_{m,n-1}^{p+1} = T_{m,n}^p$$

Nodes 6 and 14:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2} + \frac{2h\alpha\Delta t}{k\Delta y}\right) T_6^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_1^{p+1} - \frac{2\alpha\Delta t}{\Delta x^2} T_7^{p+1} = \frac{2h\alpha\Delta t}{k\Delta y} T_\infty + T_6^p$$

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2} + \frac{2h\alpha\Delta t}{k\Delta y}\right) T_{14}^{p+1} - \frac{2\alpha\Delta t}{\Delta x^2} T_{15}^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_{19}^{p+1} = \frac{2h\alpha\Delta t}{k\Delta y} T_\infty + T_{14}^p$$

PROBLEM 5.127 (Cont.)

Nodes 7 and 15:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2} + \frac{2h\alpha\Delta t}{k\Delta y}\right) T_7^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_2^{p+1} - \frac{\alpha\Delta t}{\Delta x^2} T_6^{p+1} - \frac{\alpha\Delta t}{k\Delta x^2} T_8^{p+1} = \frac{2h\alpha\Delta t}{k\Delta y} T_\infty + T_7^p$$

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2} + \frac{2h\alpha\Delta t}{k\Delta y}\right) T_{15}^{p+1} - \frac{\alpha\Delta t}{\Delta x^2} T_{14}^{p+1} - \frac{\alpha\Delta t}{\Delta x^2} T_{16}^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_{20}^{p+1} = \frac{2h\alpha\Delta t}{k\Delta y} T_\infty + T_{15}^p$$

Nodes 8 and 16:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2} + \frac{2}{3} \frac{h\alpha\Delta t}{k\Delta x} + \frac{2}{3} \frac{h\alpha\Delta t}{k\Delta y}\right) T_8^{p+1} - \frac{4}{3} \frac{\alpha\Delta t}{\Delta y^2} T_3^{p+1} - \frac{2}{3} \frac{\alpha\Delta t}{\Delta x^2} T_7^{p+1} - \frac{4}{3} \frac{\alpha\Delta t}{\Delta x^2} T_9^{p+1} - \frac{2}{3} \frac{\alpha\Delta t}{\Delta y^2} T_{11}^{p+1} = \frac{2}{3} \frac{h\alpha\Delta t}{k} \left(\frac{1}{\Delta x} + \frac{1}{\Delta y}\right) T_\infty + T_8^p$$

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2} + \frac{2}{3} + \frac{h\alpha\Delta t}{k\Delta x} + \frac{2}{3} \frac{h\alpha\Delta t}{k\Delta y}\right) T_{16}^{p+1} - \frac{2}{3} \frac{\alpha\Delta t}{\Delta y^2} T_{11}^{p+1} - \frac{2}{3} \frac{\alpha\Delta t}{\Delta x^2} T_{15}^{p+1} - \frac{4}{3} \frac{\alpha\Delta t}{\Delta x^2} T_{17}^{p+1} - \frac{4}{3} \frac{\alpha\Delta t}{\Delta y^2} T_{21}^{p+1} = \frac{2}{3} \frac{h\alpha\Delta t}{k} \left(\frac{1}{\Delta x} + \frac{1}{\Delta y}\right) T_\infty + T_{16}^p$$

Node 11:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2} + \frac{2h\alpha\Delta t}{k\Delta x}\right) T_{11}^{p+1} - \frac{\alpha\Delta t}{\Delta y^2} T_8^{p+1} - 2\alpha \frac{\Delta t}{\Delta x^2} T_{12}^{p+1} - \frac{\alpha\Delta t}{\Delta y^2} T_{16}^{p+1} = \frac{2h\alpha\Delta t}{k\Delta x} T_\infty + T_{11}^p$$

Nodes 9, 12, 17, 20, 21, 22:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2}\right) T_{m,n}^{p+1} - \frac{\alpha\Delta t}{\Delta y^2} (T_{m,n+1}^{p+1} + T_{m,n-1}^{p+1}) - \frac{\alpha\Delta t}{\Delta x^2} (T_{m-1,n}^{p+1} + T_{m+1,n}^{p+1}) = T_{m,n}^p$$

Nodes 10, 13, 18, 23:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2}\right) T_{m,n}^{p+1} - \frac{\alpha\Delta t}{\Delta y^2} (T_{m,n+1}^{p+1} + T_{m,n-1}^{p+1}) - \frac{2\alpha\Delta t}{\Delta x^2} T_{m-1,n}^{p+1} = T_{m,n}^p$$

Node 19:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2}\right) T_{19}^{p+1} - \frac{\alpha\Delta t}{\Delta y^2} (T_{14}^{p+1} + T_{24}^{p+1}) - \frac{2\alpha\Delta t}{\Delta x^2} T_{20}^{p+1} = T_{19}^p$$

Nodes 24, 28:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2}\right) T_{24}^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_{19}^{p+1} - \frac{2\alpha\Delta t}{\Delta x^2} T_{25}^{p+1} = \frac{2q_o''\alpha\Delta t}{k\Delta y} + T_{24}^p$$

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2}\right) T_{28}^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_{23}^{p+1} - \frac{2\alpha\Delta t}{\Delta x^2} T_{27}^{p+1} = \frac{2q_o''\alpha\Delta t}{k\Delta y} + T_{28}^p$$

Continued

PROBLEM 5.127 (Cont.)

Nodes 25, 26, 27:

$$\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2}\right) T_{m,n}^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_{m,n+1}^{p+1} - \frac{\alpha\Delta t}{\Delta x^2} (T_{m-1,n}^{p+1} + T_{m+1,n}^{p+1}) = \frac{2q_o''\alpha\Delta t}{k\Delta y} + T_{m,n}^{p+1}$$

The convection heat rate is

$$q'_{\text{conv}} = h \left[(\Delta x/2)(T_6 - T_\infty) + \Delta x(T_7 - T_\infty) + (\Delta x + \Delta y)(T_8 - T_\infty)/2 + \Delta y(T_{11} - T_\infty) + (\Delta x + \Delta y)(T_{16} - T_\infty)/2 + \Delta x(T_{15} - T_\infty) + (\Delta x/2)(T_{14} - T_\infty) \right] = q_{\text{out}}$$

The heat input is

$$q'_{\text{in}} = q_o''(4\Delta x)$$

and, on a percentage basis, the ratio is

$$n \equiv (q'_{\text{conv}} / q'_{\text{in}}) \times 100.$$

COMMENTS: Temperatures at $t = 23$ s are everywhere within 0.13°C of the final steady-state values.

PROBLEM 5.128

KNOWN: Cubic-shaped furnace, with prescribed operating temperature and convection heat transfer on the exterior surfaces.

FIND: Time required for the furnace to cool to a safe working temperature corresponding to an inner wall temperature of 35°C considering convection cooling on (a) the exterior surfaces and (b) on both the exterior and interior surfaces.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction through the furnace walls and (2) Constant properties.

ANALYSIS: Assuming two-dimensional conduction through the walls and taking advantage of symmetry for the cubical shape, the analysis considers the quarter section shown in the schematic above. For part (a), with no cooling on the interior during the cool-down process, the inner surface boundary condition is adiabatic. For part (b), with cooling on both the exterior and interior, the boundary conditions are prescribed by the convection process. The boundaries through the centerline of the wall and the diagonal through the corner are symmetry planes and considered as adiabatic. We have chosen to use the finite-element software *FEHT* as the solution tool.

Using *FEHT*, an outline of the symmetrical wall section is drawn, and the material properties are specified. To determine the initial conditions for the cool-down process, we will first find the temperature distribution for steady-state operation. As such, specify the boundary condition for the inner surface as a constant temperature of 900°C; the other boundaries are as earlier described. In the *Setup* menu, click on *Steady-State*, and then *Run* to obtain the steady-state temperature distribution. This distribution represents the initial temperature distribution, $T_i(x, y, 0)$, for the wall at the onset of the cool-down process.

Next, in the *Setup* menu, click on *Transient*; for the nodes on the inner surface, in the *Specify / Boundary Conditions* menu, deselect the *Temperature* box (900°C) and set the *Flux* box to zero for the adiabatic condition (part (a)); and, in the *Run* command, click on *Continue* (not *Calculate*). Be sure to change the integration time scale from *seconds* to *hours*.

Because of the high ratio of wall section width (nearly 8.5 m) to the thickness (1 m), the conduction heat transfer through the section is nearly one-dimensional. We chose the x,y-section 1 m to the right of the centerline (1 m, y) as the location for examining the temperature-time history, and determining the cool-down time for the inner surface to reach the safe working temperature of 35°C.

Continued

PROBLEM 5.128 (Cont.)

Time-to-cool, Part (a), Adiabatic inner surface. From the above temperature history, the cool-down time, t_a , corresponds to the condition when $T_a(1 \text{ m}, 0, t_a) = 35^\circ\text{C}$. As seen from the history, this location is the last to cool. From the *View / Tabular Output*, find that

$$t_a = 1306 \text{ h} = 54 \text{ days}$$

<

Continued

PROBLEM 5.128 (Cont.)

Time-to-cool, Part (b), Cooled inner surface. From the above temperature history, note that the center portion of the wall, and not the inner surface, is the last to cool. The inner surface cools to 35°C in approximately 175 h or 7 days. However, if the cooling process on the inner surface were discontinued, its temperature would increase and eventually exceed the desired safe working temperature. To assure the safe condition will be met, estimate the cool down time as, t_b , corresponding to the condition when $T_b(1 \text{ m}, 0.75 \text{ m}, t_b) = 35^\circ\text{C}$. From the *View / Tabular Output*, find that

$$t_b = 311 \text{ h} = 13 \text{ days}$$

<

COMMENTS: (1) Assuming the furnace can be approximated by a two-dimensional symmetrical section greatly simplifies our analysis by not having to deal with three-dimensional corner effects. We justify this assumption on the basis that the corners represent a much shorter heat path than the straight wall section. Considering corner effects would reduce the cool-down time estimates; hence, our analysis provides a conservative estimate.

(2) For background information on the *Continue* option, see the *Run* menu in the *FEHT Help* section. Using the *Run | Calculate* command, the steady-state temperature distribution was determined for the normal operating condition of the furnace. Using the *Run | Continue* command (after clicking on *Setup / Transient*), this steady-state distribution automatically becomes the initial temperature distribution for the cool-down transient process. This feature allows for conveniently prescribing a non-uniform initial temperature distribution for a transient analysis (rather than specifying values on a node-by-node basis).

PROBLEM 5.129

KNOWN: Door panel with ribbed cross-section, initially at a uniform temperature of 275°C , is ejected from the hot extrusion press and experiences convection cooling with ambient air at 25°C and a convection coefficient of $10 \text{ W/m}^2\cdot\text{K}$.

FIND: (a) Using the *FEHT View|Temperature vs. Time* command, create a graph with temperature-time histories of selected locations on the panel surface, $T(x,0,t)$. Comment on whether you see noticeable differential cooling in the region above the rib that might explain the appearance defect; and Using the *View|Temperature Contours* command with the shaded-band option for the isotherm contours, select the *From start to stop* time option, and view the temperature contours as the panel cools. Describe the major features of the cooling process you have seen. Use other options of this command to create a 10-isotherm temperature distribution at some time that illustrates important features. How would you re-design the ribbed panel in order to reduce this thermally induced paint defect situation, yet retain the stiffening function required of the ribs?

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction in the panel, (2) Uniform convection coefficient over the upper and lower surfaces of the panel, (3) Constant properties.

PROPERTIES: Door panel material (*given*): $\rho = 1050 \text{ kg/m}^3$, $c = 800 \text{ J/kg}\cdot\text{K}$, $k = 0.5 \text{ W/m}\cdot\text{K}$.

ANALYSIS:

(a) Using the *Draw* command, the shape of the symmetrical element of the panel (darkened region in schematic) was generated and elements formed as shown below. The symmetry lines represent adiabatic surfaces, while the boundary conditions for the exposed web and rib surfaces are characterized by (T_∞, h) .

Continued

PROBLEM 5.129 (Cont.)

After running the calculation for the time period 0 to 400 s with a 1-second time step, the temperature-time histories for three locations were obtained and the graph is shown below.

As expected, the region directly over the rib (0,0) cooled the slowest, while the extreme portion of the web (0, 13 mm) cooled the fastest. The largest temperature differences between these two locations occur during the time period 50 to 150 s. The maximum difference does not exceed 25°C.

Continued

PROBLEM 5.129 (Cont.)

(b) It is possible that the temperature gradients within the web-rib regions – rather than just the upper surface temperature differentials – might be important for understanding the panel's response to cooling. Using the *Temperature Contours* command (with the *From start to stop* option), we saw that the center portion of the web and the end of the rib cooled quickly, but that the region on the rib centerline (0, 3-5 mm), was the hottest region. The isotherms corresponding to $t = 100$ s are shown below. For this condition, the temperature differential is about 21°C .

From our analyses, we have identified two possibilities to consider. First, there is a significant surface temperature distribution across the panel during the cooling process. Second, the web and the extended portion of the rib cool at about the same rate, and with only a modest normal temperature gradient. The last region to cool is at the location where the rib is thickest (0, 3-5 mm). The large temperature gradient along the centerline toward the surface may be the cause of microstructure variations, which could influence the adherence of paint. An obvious re-design consideration is to reduce the thickness of the rib at the web joint, thereby reducing the temperature gradients in that region. This fix comes at the expense of decreasing the spacing between the ribs.

PROBLEM 5S.1

KNOWN: Configuration, initial temperature and charging conditions of a thermal energy storage unit.

FIND: Time required to achieve 75% of maximum possible energy storage and corresponding minimum and maximum temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible radiation exchange with surroundings.

ANALYSIS: For the system, find first

$$Bi = \frac{hL}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 0.025 \text{ m}}{0.7 \text{ W/m} \cdot \text{K}} = 3.57$$

indicating that the lumped capacitance method cannot be used.

Grober chart, Fig. 5S.3: $Q/Q_o = 0.75$

$$\alpha = \frac{k}{\rho c} = \frac{0.7 \text{ W/m} \cdot \text{K}}{1900 \text{ kg/m}^3 \times 800 \text{ J/kg} \cdot \text{K}} = 4.605 \times 10^{-7} \text{ m}^2/\text{s}$$

$$Bi^2 Fo = \frac{h^2 \alpha t}{k^2} = \frac{(100 \text{ W/m}^2 \cdot \text{K})^2 \times (4.605 \times 10^{-7} \text{ m}^2/\text{s}) \times t(\text{s})}{(0.7 \text{ W/m} \cdot \text{K})^2} = 9.4 \times 10^{-3} t$$

Find $Bi^2 Fo \approx 11$, and substituting numerical values

$$t = 11/9.4 \times 10^{-3} = 1170 \text{ s.} \quad <$$

Heisler chart, Fig. 5S.1: T_{\min} is at $x = 0$ and T_{\max} at $x = L$, with

$$Fo = \frac{\alpha t}{L^2} = \frac{4.605 \times 10^{-7} \text{ m}^2/\text{s} \times 1170 \text{ s}}{(0.025 \text{ m})^2} = 0.86 \quad Bi^{-1} = 0.28.$$

From Fig. 5S.1, $\theta_o^* \approx 0.33$. Hence,

$$T_o \approx T_{\infty} + 0.33(T_i - T_{\infty}) = 600^\circ\text{C} + 0.33(-575^\circ\text{C}) = 410^\circ\text{C} = T_{\min}. \quad <$$

From Fig. 5S.2, $\theta/\theta_o \approx 0.33$ at $x = L$, for which

$$T_{x=L} \approx T_{\infty} + 0.33(T_o - T_{\infty}) = 600^\circ\text{C} + 0.33(-190)^\circ\text{C} = 537^\circ\text{C} = T_{\max}. \quad <$$

COMMENTS: Comparing masonry (m) with aluminum (Al), see Problem 5.11, $(\rho c)_{Al} > (\rho c)_m$ and $k_{Al} > k_m$. Hence, the aluminum can store more energy and can be charged (or discharged) more quickly.

PROBLEM 5S.10

KNOWN: Initial temperature of fire clay brick which is cooled by convection.

FIND: Center and corner temperatures after 50 minutes of cooling.

SCHEMATIC:

ASSUMPTIONS: (1) Homogeneous medium with constant properties, (2) Negligible radiation effects.

PROPERTIES: Table A-3, Fire clay brick (900K): $\rho = 2050\text{ kg/m}^3$, $k = 1.0\text{ W/m}\cdot\text{K}$, $c_p = 960\text{ J/kg}\cdot\text{K}$. $\alpha = 0.51 \times 10^{-6}\text{ m}^2/\text{s}$.

ANALYSIS: From Figure 5S.11(h), the center temperature is given by

$$\frac{T(0,0,0,t) - T_\infty}{T_i - T_\infty} = P_1(0,t) \times P_2(0,t) \times P_3(0,t)$$

where P_1 , P_2 and P_3 must be obtained from Figure 5S.1.

$$\begin{aligned} L_1 = 0.03\text{m}: \quad Bi_1 &= \frac{h L_1}{k} = 1.50 & Fo_1 &= \frac{\alpha t}{L_1^2} = 1.70 \\ L_2 = 0.045\text{m}: \quad Bi_2 &= \frac{h L_2}{k} = 2.25 & Fo_2 &= \frac{\alpha t}{L_2^2} = 0.756 \\ L_3 = 0.10\text{m}: \quad Bi_3 &= \frac{h L_3}{k} = 5.0 & Fo_3 &= \frac{\alpha t}{L_3^2} = 0.153 \end{aligned}$$

Hence from Figure 5S.1,

$$P_1(0,t) \approx 0.22 \quad P_2(0,t) \approx 0.50 \quad P_3(0,t) \approx 0.85.$$

Hence,

$$\frac{T(0,0,0,t) - T_\infty}{T_i - T_\infty} \approx 0.22 \times 0.50 \times 0.85 = 0.094$$

and the center temperature is

$$T(0,0,0,t) \approx 0.094(1600 - 313)\text{K} + 313\text{K} = 434\text{K}.$$

<

Continued

PROBLEM 5S.10 (Cont.)

The corner temperature is given by

$$\frac{T(L_1, L_2, L_3, t) - T_\infty}{T_i - T_\infty} = P(L_1, t) \times P(L_2, t) \times P(L_3, t)$$

where

$$P(L_1, t) = \frac{\theta(L_1, t)}{\theta_o} \cdot P_1(0, t), \text{ etc.}$$

and similar forms can be written for L_2 and L_3 . From Figure 5S.2,

$$\frac{\theta(L_1, t)}{\theta_o} \approx 0.55 \quad \frac{\theta(L_2, t)}{\theta_o} \approx 0.43 \quad \frac{\theta(L_3, t)}{\theta_o} \approx 0.25.$$

Hence,

$$\begin{aligned} P(L_1, t) &\approx 0.55 \times 0.22 = 0.12 \\ P(L_2, t) &\approx 0.43 \times 0.50 = 0.22 \\ P(L_3, t) &\approx 0.85 \times 0.25 = 0.21 \end{aligned}$$

and

$$\frac{T(L_1, L_2, L_3, t) - T_\infty}{T_i - T_\infty} \approx 0.12 \times 0.22 \times 0.21 = 0.0056$$

or

$$T(L_1, L_2, L_3, t) \approx 0.0056(1600 - 313)\text{K} + 313\text{K}.$$

The corner temperature is then

$$T(L_1, L_2, L_3, t) \approx 320\text{K}.$$

<

COMMENTS: (1) The foregoing temperatures are overpredicted by ignoring radiation, which is significant during the early portion of the transient.

(2) Note that, if the time required to reach a certain temperature were to be determined, an iterative approach would have to be used. The foregoing procedure would be used to compute the temperature for an assumed value of the time, and the calculation would be repeated until the specified temperature were obtained.

PROBLEM 5S.11

KNOWN: Cylindrical copper pin, 100 mm long \times 50 mm diameter, initially at 20°C; end faces are subjected to intense heating, suddenly raising them to 500°C; at the same time, the cylindrical surface is subjected to a convective heating process (T_∞, h).

FIND: (a) Temperature at center point of cylinder after a time of 8 seconds from sudden application of heat, (b) Consider parameters governing transient diffusion and justify simplifying assumptions that could be applied to this problem.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Constant properties and convection heat transfer coefficient.

PROPERTIES: Table A-1, Copper, pure ($\bar{T} \approx (500 + 20)^\circ \text{C} / 2 \approx 500\text{K}$): $\rho = 8933 \text{ kg/m}^3$, $c = 407$

$\text{J/kg}\cdot\text{K}$, $k = 386 \text{ W/m}\cdot\text{K}$, $\alpha = k/\rho c = 386 \text{ W/m}\cdot\text{K} / 8933 \text{ kg/m}^3 \times 407 \text{ J/kg}\cdot\text{K} = 1.064 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: (1) The pin can be treated as a two-dimensional system comprised of an infinite cylinder whose surface is exposed to a convection process (T_∞, h) and of a plane wall whose surfaces are maintained at a constant temperature (T_e). This configuration corresponds to the short cylinder, Case (i) of Figure 5S.11,

$$\frac{\theta(r, x, t)}{\theta_i} = C(r, t) \times P(x, t). \quad (1)$$

For the infinite cylinder, using Figure 5S.4, with

$$\text{Bi} = \frac{hr_o}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} (25 \times 10^{-3} \text{ m})}{386 \text{ W/m}\cdot\text{K}} = 6.47 \times 10^{-3} \quad \text{and} \quad \text{Fo} = \frac{\alpha t}{r_o^2} = \frac{1.064 \times 10^{-4} \text{ m}^2/\text{s} \times 8 \text{ s}}{(25 \times 10^{-3} \text{ m})^2} = 1.36,$$

$$\text{find} \quad C(0, 8\text{s}) = \left. \frac{\theta(0, 8\text{s})}{\theta_i} \right]_{\text{cyl}} \approx 1. \quad (2)$$

For the infinite plane wall, using Figure 5S.1, with

$$\text{Bi} = \frac{hL}{k} \rightarrow \infty \quad \text{or} \quad \text{Bi}^{-1} \rightarrow 0 \quad \text{and} \quad \text{Fo} = \frac{\alpha t}{L^2} = \frac{1.064 \times 10^{-4} \text{ m}^2/\text{s} \times 8 \text{ s}}{(50 \times 10^{-3} \text{ m})^2} = 0.34, \\ \text{find} \quad P(0, 8\text{s}) = \left. \frac{\theta(0, 8\text{s})}{\theta_i} \right]_{\text{wall}} \approx 0.5. \quad (3)$$

Combining Equations (2) and (3) with Eq. (1), find $\frac{\theta(0, 0, 8\text{s})}{\theta_i} = \frac{T(0, 0, 8\text{s}) - T_\infty}{T_i - T_\infty} \approx 1 \times 0.5 = 0.5$

$$T(0, 0, 8\text{s}) = T_\infty + 0.5(T_i - T_\infty) = 500 + 0.5(20 - 500) = 260^\circ \text{C}. \quad <$$

(b) The parameters controlling transient conduction with convective boundary conditions are the Biot and Fourier numbers. Since $\text{Bi} \ll 0.1$ for the cylindrical shape, we can assume radial gradients are negligible. That is, we need only consider conduction in the x -direction.

PROBLEM 5S.12

KNOWN: Cylindrical-shaped meat roast weighing 2.25 kg, initially at 6°C, is placed in an oven and subjected to convection heating with prescribed (T_∞, h).

FIND: Time required for the center to reach a done temperature of 80°C.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction in x and r directions, (2) Uniform and constant properties, (3) Properties approximated as those of water.

PROPERTIES: Table A-6, Water, liquid ($\bar{T} = (80 + 6)^\circ\text{C}/2 \approx 315\text{K}$): $\rho = 1/v_f = 1/1.009 \times 10^{-3} \text{ m}^3/\text{kg} = 991.1 \text{ kg/m}^3$, $c_{p,f} = 4179 \text{ J/kg}\cdot\text{K}$, $k = 0.634 \text{ W/m}\cdot\text{K}$, $\alpha = k/\rho c_p = 1.531 \times 10^{-7} \text{ m}^2/\text{s}$.

ANALYSIS: The dimensions of the roast are determined from the requirement $r_o = L$ and knowledge of its weight and density,

$$M = \rho V = \rho \cdot 2L \cdot \pi r_o^2 \quad \text{or} \quad r_o = L = \left[\frac{M}{2\pi\rho} \right]^{1/3} = \left[\frac{2.25 \text{ kg}}{2\pi(991.1 \text{ kg/m}^3)} \right]^{1/3} = 0.0712 \text{ m}. \quad (1)$$

The roast corresponds to Case (i), Figure 5S.11, and the temperature distribution may be expressed as the product of one-dimensional solutions,

$$\frac{T(x,r,t) - T_\infty}{T_i - T_\infty} = P(x,t) \times C(r,t),$$

where $P(x,t)$ and $C(r,t)$ are defined by Equations 5S.2 and 5S.3, respectively. For the center of the cylinder,

$$\frac{T(0,0,t) - T_\infty}{T_i - T_\infty} = \frac{(80 - 175)^\circ\text{C}}{(6 - 175)^\circ\text{C}} = 0.56. \quad (2)$$

In terms of the product solutions,

$$\frac{T(0,0,t) - T_\infty}{T_i - T_\infty} = 0.56 = \left[\frac{T(0,t) - T_\infty}{T_i - T_\infty} \right]_{\text{wall}} \times \left[\frac{T(0,t) - T_\infty}{T_i - T_\infty} \right]_{\text{cylinder}} \quad (3)$$

For each of these shapes, we need to find values of θ_o/θ_i such that their product satisfies Equation (3). For both shapes,

$$\text{Bi} = \frac{h r_o}{k} = \frac{hL}{k} = \frac{15 \text{ W/m}^2 \cdot \text{K} \times 0.0712 \text{ m}}{0.634 \text{ W/m}\cdot\text{K}} = 1.68 \quad \text{or} \quad \text{Bi}^{-1} \approx 0.6$$

$$\text{Fo} = \alpha t/r_o^2 = \alpha t/L^2 = 1.53 \times 10^{-7} \text{ m}^2/\text{s} \times t / (0.0712 \text{ m})^2 = 3.020 \times 10^{-5} t.$$

Continued

PROBLEM 5S.12 (Cont.)

A trial-and-error solution is necessary. Begin by assuming a value of Fo ; obtain the respective θ_o/θ_i values from Figures 5S.1 and 5S.4; test whether their product satisfies Equation (3). Two trials are shown as follows:

<i>Trial</i>	Fo	$t(\text{hrs})$	$\theta_o/\theta_i)_{\text{wall}}$	$\theta_o/\theta_i)_{\text{cyl}}$	$\left. \frac{\theta_o}{\theta_i} \right]_{\text{w}} \times \left. \frac{\theta_o}{\theta_i} \right]_{\text{cyl}}$
1	0.4	3.68	0.72	0.50	0.36
2	0.3	2.75	0.78	0.68	0.53

For Trial 2, the product of 0.53 agrees closely with the value of 0.56 from Equation (2). Hence, it will take approximately $2 \frac{3}{4}$ hours to roast the meat.

PROBLEM 5S.13

KNOWN: A long alumina rod, initially at a uniform temperature of 850 K, is suddenly exposed to a cooler fluid.

FIND: Temperature of the rod after 30 s, at an exposed end, $T(0,0,t)$, and at an axial distance 6mm from the end, $T(0, 6 \text{ mm}, t)$.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction in (r,x) directions, (2) Constant properties, (3) Convection coefficient is same on end and cylindrical surfaces.

PROPERTIES: Table A-2, Alumina, polycrystalline aluminum oxide (assume $\bar{T} \approx (850 + 600) \text{ K} / 2 = 725 \text{ K}$): $\rho = 3970 \text{ kg/m}^3$, $c = 1154 \text{ J/kg}\cdot\text{K}$, $k = 12.4 \text{ W/m}\cdot\text{K}$.

ANALYSIS: First, check if system behaves as a lumped capacitance. Find

$$Bi = \frac{hL_c}{k} = \frac{h(r_o/2)}{k} = \frac{500 \text{ W/m}\cdot\text{K} (0.010 \text{ m}/2)}{12.4 \text{ W/m}\cdot\text{K}} = 0.202.$$

Since $Bi > 0.1$, rod does not behave as spacewise isothermal object. Hence, treat rod as a semi-infinite cylinder, the multi-dimensional system Case (f), Figure 5S.11.

The product solution can be written as

$$\theta^*(r,x,t) = \frac{\theta(r,x,t)}{\theta_i} = \frac{\theta(r,t)}{\theta_i} \times \frac{\theta(x,t)}{\theta_i} = C(r^*, t^*) \times S(x^*, t^*)$$

Infinite cylinder, $C(r^, t^*)$.* Using the Heisler charts with $r^* = r = 0$ and

$$Bi^{-1} = \left[\frac{h r_o}{k} \right]^{-1} = \left[\frac{500 \text{ W/m}^2 \cdot \text{K} \times 0.01 \text{ m}}{12.4 \text{ W/m}\cdot\text{K}} \right]^{-1} = 2.48.$$

Evaluate $\alpha = k/\rho c = 2.71 \times 10^{-6} \text{ m}^2/\text{s}$, find $Fo = \alpha t/r_o^2 = 2.71 \times 10^{-6} \text{ m}^2/\text{s} \times 30 \text{ s}/(0.01 \text{ m})^2 = 0.812$. From the Heisler chart, Figure 5S.4, with $Bi^{-1} = 2.48$ and $Fo = 0.812$, read $C(0, t^*) = \theta(0, t)/\theta_i = 0.61$.

Continued

PROBLEM 5S.13 (Cont.)

Semi-infinite medium, $S(x^, t^*)$.* Recognize this as Case (3), Figure 5.7. From Equation 5.60, note that the LHS needs to be transformed as follows,

$$\frac{T - T_i}{T_\infty - T_i} = 1 - \frac{T - T_\infty}{T_i - T_\infty} \quad S(x, t) = \frac{T - T_\infty}{T_i - T_\infty}.$$

Thus,

$$S(x, t) = 1 - \left\{ \operatorname{erfc} \left[\frac{x}{2(\alpha t)^{1/2}} \right] - \left[\exp \left[\frac{hx}{k} + \frac{h^2 \alpha t}{k^2} \right] \right] \left[\operatorname{erfc} \left[\frac{x}{2(\alpha t)^{1/2}} + \frac{h(\alpha t)^{1/2}}{k} \right] \right] \right\}.$$

Evaluating this expression at the surface ($x = 0$) and 6 mm from the exposed end, find

$$S(0, 30s) = 1 - \left\{ \operatorname{erfc}(0) - \left[\exp \left[0 + \frac{(500 \text{ W/m}^2 \cdot \text{K})^2 2.71 \times 10^{-6} \text{ m}^2 / \text{s} \times 30s}{(12.4 \text{ W/m} \cdot \text{K})^2} \right] \right] \left[\operatorname{erfc} \left[0 + \frac{500 \text{ W/m}^2 \cdot \text{K} (2.71 \times 10^{-6} \text{ m}^2 / \text{s} \times 30s)^{1/2}}{12.4 \text{ W/m} \cdot \text{K}} \right] \right] \right\}$$

$$S(0, 30s) = 1 - \{ 1 - [\exp(0.1322)] [\operatorname{erfc}(0.3636)] \} = 0.693.$$

Note that Table B.2 was used to evaluate the complementary error function, $\operatorname{erfc}(w)$.

$$S(6\text{mm}, 30s) = 1 - \left\{ \operatorname{erfc} \left[\frac{0.006\text{m}}{2(2.71 \times 10^{-6} \text{ m}^2 / \text{s} \times 30s)^{1/2}} \right] - \left[\exp \left[\frac{500 \text{ W/m}^2 \cdot \text{K} \times 0.006\text{m}}{12.4 \text{ W/m} \cdot \text{K}} + 0.1322 \right] \right] \left[\operatorname{erfc}(0.3327 + 0.3636) \right] \right\} = 0.835.$$

The product solution can now be evaluated for each location. At (0,0),

$$\theta^*(0, 0, t) = \frac{T(0, 0, 30s) - T_\infty}{T_i - T_\infty} = C(0, t^*) \times S(0, t^*) = 0.61 \times 0.693 = 0.423.$$

Hence, $T(0, 0, 30s) = T_\infty + 0.423(T_i - T_\infty) = 350\text{K} + 0.423(850 - 350)\text{K} = 561 \text{ K.} <$

At (0,6mm),

$$\theta^*(0, 6\text{mm}, t) = C(0, t^*) \times S(6\text{mm}, t^*) = 0.61 \times 0.835 = 0.509$$

$$T(0, 6\text{mm}, 30s) = 604 \text{ K.} <$$

COMMENTS: Note that the temperature at which the properties were evaluated was a good estimate.

PROBLEM 5S.14

KNOWN: Stainless steel cylinder of Example 5S.1, 80-mm diameter by 60-mm length, initially at 600 K, suddenly quenched in an oil bath at 300 K with $h = 500 \text{ W/m}^2 \cdot \text{K}$. Use the *Transient Conduction, Plane Wall and Cylinder* models of *IHT* to obtain the following solutions.

FIND: (a) Calculate the temperatures $T(r, x, t)$ after 3 min: at the cylinder center, $T(0, 0, 3 \text{ min})$, at the center of a circular face, $T(0, L, 3 \text{ min})$, and at the midheight of the side, $T(r_o, 0, 3 \text{ min})$; compare your results with those in the example; (b) Calculate and plot temperature histories at the cylinder center, $T(0, 0, t)$, the mid-height of the side, $T(r_o, 0, t)$, for $0 \leq t \leq 10 \text{ min}$; comment on the gradients and what effect they might have on phase transformations and thermal stresses; and (c) For $0 \leq t \leq 10 \text{ min}$, calculate and plot the temperature histories at the cylinder center, $T(0, 0, t)$, for convection coefficients of 500 and $1000 \text{ W/m}^2 \cdot \text{K}$.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction in r - and x -coordinates, (2) Constant properties.

PROPERTIES: Stainless steel (*Example 5S.1*): $\rho = 7900 \text{ kg/m}^3$, $c = 526 \text{ J/kg} \cdot \text{K}$, $k = 17.4 \text{ W/m} \cdot \text{K}$.

ANALYSIS: The following results were obtained using the *Transient Conduction* models for the *Plane Wall* and *Cylinder* of *IHT*. Salient portions of the code are provided in the Comments.

(a) Following the methodology for a product solution outlined in Example 5S.1, the following results were obtained at $t = t_o = 3 \text{ min}$

(r, x, t)	$P(x, t)$	$C(r, t)$	$T(r, x, t)$ -IHT (K)	$T(r, x, t)$ -Ex (K)
$0, 0, t_o$	0.6357	0.5388	402.7	405
$0, L, t_o$	0.4365	0.5388	370.5	372
$r_o, 0, t_o$	0.6357	0.3273	362.4	365

Continued

PROBLEM 5S.14 (Cont.)

The temperatures from the one-term series calculations of the Example 5S.1 are systematically higher than those resulting from the *IHT* multiple-term series model, which is the more accurate method.

(b) The temperature histories for the center and mid-height of the side locations are shown in the graph below. Note that at early times, the temperature difference between these locations, and hence the gradient, is large. Large differences could cause variations in microstructure and hence, mechanical properties, as well as induce residual thermal stresses.

(c) Effect of doubling the convection coefficient is to increase the quenching rate, but much less than by a factor of two as can be seen in the graph below.

COMMENTS: From *IHT* menu for *Transient Conduction* | *Plane Wall* and *Cylinder*, the models were combined to solve the product solution. Key portions of the code, less the input variables, are copied below.

```
// Plane wall temperature distribution
// The temperature distribution is
T_xtP = T_xt_trans("Plane Wall",xstar,FoP,BiP,Ti,Tinf) // Eq 5.39
// The dimensionless parameters are
xstar = x / L
BiP = h * L / k // Eq 5.9
FoP = alpha * t / L^2 // Eq 5.33
alpha = k / (rho * cp)
// Dimensionless representation, P(x,t)
P_xt = (T_xtP - Tinf) / (Ti - Tinf)

// Cylinder temperature distribution
// The temperature distribution T(r,t) is
T_rtC = T_xt_trans("Cylinder",rstar,FoC,BiC,Ti,Tinf) // Eq 5.47
// The dimensionless parameters are
rstar = r / ro
BiC = h * ro / k
FoC = alpha * t / ro^2
// Dimensionless representation, C(r,t)
C_rt = (T_rtC - Tinf) / (Ti - Tinf)

// Product solution temperature distribution
(T_xrt - Tinf) / (Ti - Tinf) = P_xt * C_rt
```

PROBLEM 5S.2

KNOWN: Car windshield, initially at a uniform temperature of -20°C , is suddenly exposed on its interior surface to the defrost system airstream at 30°C . The ice layer on the exterior surface acts as an insulating layer.

FIND: What airstream convection coefficient would allow the exterior surface to reach 0°C in 60 s?

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in the windshield, (2) Constant properties, (3) Exterior surface is perfectly insulated.

PROPERTIES: Windshield (Given): $\rho = 2200\text{ kg/m}^3$, $c_p = 830\text{ J/kg}\cdot\text{K}$ and $k = 1.2\text{ W/m}\cdot\text{K}$.

ANALYSIS: For the prescribed conditions, from Equations 5.31 and 5.33,

$$\frac{\theta(0, 60\text{s})}{\theta_i} = \frac{\theta_o}{\theta_i} = \frac{T(0, 60\text{s}) - T_{\infty}}{T_i - T_{\infty}} = \frac{(0 - 30)^{\circ}\text{C}}{(-20 - 30)^{\circ}\text{C}} = 0.6$$

$$\text{Fo} = \frac{kt}{\rho c L^2} = \frac{1.2\text{ W/m}\cdot\text{K} \times 60}{2200\text{ kg/m}^3 \times 830\text{ J/kg}\cdot\text{K} \times (0.005\text{ m})^2} = 1.58$$

The single-term series approximation, Eq. 5.41, along with Table 5.1, requires an iterative solution to find an appropriate Biot number. Alternatively, the Heisler charts, Section 5S.1, Figure 5S.1, for the midplane temperature could be used to find

$$\text{Bi}^{-1} = k/hL = 2.5$$

$$h = 1.2\text{ W/m}\cdot\text{K} / 2.5 \times 0.005\text{ m} = 96\text{ W/m}^2\cdot\text{K}$$

<

COMMENTS: Using the *IHT, Transient Conduction, Plane Wall Model*, the convection coefficient can be determined by solving the model with an assumed h and then sweeping over a range of h until the $T(0, 60\text{s})$ condition is satisfied. Since the model is based upon multiple terms of the series, the result of $h = 99\text{ W/m}^2\cdot\text{K}$ is more precise than that found using the chart.

PROBLEM 5S.3

KNOWN: Inlet and outlet temperatures of steel rods heat treated by passage through an oven.

FIND: Rod speed, V .

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction (axial conduction is negligible), (2) Constant properties, (3) Negligible radiation.

PROPERTIES: Table A-1, AISI 1010 Steel ($\bar{T} \approx 600\text{K}$): $k = 48.8 \text{ W/m}\cdot\text{K}$, $\rho = 7832 \text{ kg/m}^3$, $c_p = 559 \text{ J/kg}\cdot\text{K}$, $\alpha = (k/\rho c_p) = 1.11 \times 10^{-5} \text{ m}^2/\text{s}$.

ANALYSIS: The time needed to traverse the rod through the oven may be found from Figure 5S.4.

$$\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = \frac{600 - 750}{50 - 750} = 0.214$$

$$\text{Bi}^{-1} \equiv \frac{k}{hr_o} = \frac{48.8 \text{ W/m}\cdot\text{K}}{125 \text{ W/m}^2 \cdot \text{K} (0.025 \text{ m})} = 15.6.$$

Hence,

$$\text{Fo} = \alpha t / r_o^2 \approx 12.2$$

$$t = 12.2 (0.025 \text{ m})^2 / 1.11 \times 10^{-5} \text{ m}^2 / \text{s} = 687 \text{ s}.$$

The rod velocity is

$$V = \frac{L}{t} = \frac{5 \text{ m}}{687 \text{ s}} = 0.0073 \text{ m/s}.$$

COMMENTS: (1) Since $(h r_o / 2) / k = 0.032$, the lumped capacitance method could have been used. From Equation 5.5 it follows that $t = 675 \text{ s}$.

(2) Radiation effects decrease t and hence increase V , assuming there is net radiant transfer from the oven walls to the rod.

(3) Since $\text{Fo} > 0.2$, the approximate analytical solution may be used. With $\text{Bi} = hr_o/k = 0.0641$, Table 5.1 yields $\zeta_1 = 0.3549$ rad and $C_1 = 1.0158$. Hence from Equation 5.49c

$$\text{Fo} = -\left(\zeta_1^2\right)^{-1} \ln \left[\frac{\theta_o^*}{C_1} \right] = 12.4,$$

which is in good agreement with the graphical result.

PROBLEM 5S.4

KNOWN: Hot dog with prescribed thermophysical properties, initially at 6°C, is immersed in boiling water.

FIND: Time required to bring centerline temperature to 80°C.

SCHEMATIC:

ASSUMPTIONS: (1) Hot dog can be treated as infinite cylinder, (2) Constant properties.

ANALYSIS: The Biot number, based upon Equation 5.10, is

$$Bi \equiv \frac{h L_c}{k} = \frac{h r_o / 2}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} (10 \times 10^{-3} \text{ m} / 2)}{0.52 \text{ W/m} \cdot \text{K}} = 0.96$$

Since $Bi > 0.1$, a lumped capacitance analysis is not appropriate. Using the Heisler chart, Figure 5S.4 with

$$Bi \equiv \frac{h r_o}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 10 \times 10^{-3} \text{ m}}{0.52 \text{ W/m} \cdot \text{K}} = 1.92 \quad \text{or} \quad Bi^{-1} = 0.52$$

$$\text{and} \quad \theta_o^* = \frac{\theta_o}{\theta_i} = \frac{T(0,t) - T_\infty}{T_i - T_\infty} = \frac{(80 - 100)^\circ \text{C}}{(6 - 100)^\circ \text{C}} = 0.21 \quad (1)$$

$$\text{find} \quad Fo = t^* = \frac{\alpha t}{r_o^2} = 0.8 \quad t = \frac{r_o^2}{\alpha} \cdot Fo = \frac{(10 \times 10^{-3} \text{ m})^2}{1.764 \times 10^{-7} \text{ m}^2 / \text{s}} \times 0.8 = 453.5 \text{ s} = 7.6 \text{ min} <$$

$$\text{where} \quad \alpha = k / \rho c = 0.52 \text{ W/m} \cdot \text{K} / 880 \text{ kg/m}^3 \times 3350 \text{ J/kg} \cdot \text{K} = 1.764 \times 10^{-7} \text{ m}^2 / \text{s}.$$

COMMENTS: (1) Note that $L_c = r_o / 2$ when evaluating the Biot number for the lumped capacitance analysis; however, in the Heisler charts, $Bi \equiv h r_o / k$.

(2) The surface temperature of the hot dog follows from use of Figure 5S.5 with $r/r_o = 1$ and $Bi^{-1} = 0.52$; find $\theta(1,t)/\theta_o \approx 0.45$. From Equation (1), note that $\theta_o = 0.21 \theta_i$ giving

$$\theta(1,t) = T(r_o,t) - T_\infty = 0.45 \theta_o = 0.45 (0.21 [T_i - T_\infty]) = 0.45 \times 0.21 [6 - 100]^\circ \text{C} = -8.9^\circ \text{C}$$

$$T(r_o,t) = T_\infty - 8.9^\circ \text{C} = (100 - 8.9)^\circ \text{C} = 91.1^\circ \text{C}$$

(3) Since $Fo \geq 0.2$, the approximate solution for θ^* , Equation 5.49, is valid. From Table 5.1 with $Bi = 1.92$, find that $\zeta_1 = 1.3245$ rad and $C_1 = 1.2334$. Rearranging Equation 5.49 and substituting values,

$$Fo = -\frac{1}{\zeta_1^2} \ln \left(\theta_o^* / C_1 \right) = \frac{1}{(1.3245 \text{ rad})^2} \ln \left[\frac{0.213}{1.2334} \right] = 1.00$$

This result leads to a value of $t = 9.5$ min or 20% higher than that of the graphical method.

PROBLEM 5S.5

KNOWN: Long bar of 70 mm diameter, initially at 90°C, is suddenly immersed in a water bath ($T_\infty = 40^\circ\text{C}$, $h = 20 \text{ W/m}^2 \cdot \text{K}$).

FIND: (a) Time, t_f , that bar should remain in bath in order that, when removed and allowed to equilibrate while isolated from surroundings, it will have a uniform temperature $T(r, \infty) = 55^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties.

PROPERTIES: Bar (given): $\rho = 2600 \text{ kg/m}^3$, $c = 1030 \text{ J/kg} \cdot \text{K}$, $k = 3.50 \text{ W/m} \cdot \text{K}$, $\alpha = k/\rho c = 1.31 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: Determine first whether conditions are space-wise isothermal

$$Bi = \frac{hL_c}{k} = \frac{h(r_o/2)}{k} = \frac{20 \text{ W/m}^2 \cdot \text{K} (0.035 \text{ m}/2)}{3.50 \text{ W/m} \cdot \text{K}} = 0.10$$

and since $Bi \geq 0.1$, a Heisler solution is appropriate.

(a) Consider an overall energy balance on the bar during the time interval $\Delta t = t_f$ (the time the bar is in the bath).

$$E_{\text{in}} - E_{\text{out}} = \Delta E$$

$$0 - Q = E_{\text{final}} - E_{\text{initial}} = Mc(T_f - T_\infty) - Mc(T_i - T_\infty)$$

$$-Q = Mc(T_f - T_\infty) - Q_0$$

$$\frac{Q}{Q_0} = 1 - \frac{T_f - T_\infty}{T_i - T_\infty} = 1 - \frac{(55 - 40)^\circ\text{C}}{(90 - 40)^\circ\text{C}} = 0.70$$

where Q_0 is the initial energy in the bar (relative to T_∞ ; Equation 5.44). With $Bi = hr_o/k = 0.20$ and $Q/Q_0 = 0.70$, use Figure 5S.6 to find $Bi^2 Fo = 0.15$; hence $Fo = 0.15/Bi^2 = 3.75$ and

$$t_f = Fo \cdot r_o^2 / \alpha = 3.75 (0.035 \text{ m})^2 / 1.31 \times 10^{-6} \text{ m}^2/\text{s} = 3507 \text{ s.} \quad <$$

(b) To determine $T(r_o, t_f)$, use Figures 5S.4 and 5S.5 for $\theta(r_o, t)/\theta_i$ ($Fo = 3.75$, $Bi^{-1} = 5.0$) and θ_o/θ_i ($Bi^{-1} = 5.0$, $r/r_o = 1$, respectively, to find

$$T(r_o, t_f) = T_\infty + \frac{\theta(r_o, t)}{\theta_o} \cdot \frac{\theta_o}{\theta_i} \cdot \theta_i = 40^\circ\text{C} + 0.25 \times 0.90 (90 - 40)^\circ\text{C} = 51^\circ\text{C.} \quad <$$

PROBLEM 5S.6

KNOWN: An 80 mm sphere, initially at a uniform elevated temperature, is quenched in an oil bath with prescribed T_∞ , h .

FIND: The center temperature of the sphere, $T(0,t)$ at a certain time when the surface temperature is $T(r_o,t) = 150^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Initial uniform temperature within sphere, (3) Constant properties, (4) $Fo \geq 0.2$.

ANALYSIS: Check first to see if the sphere is spacewise isothermal.

$$Bi_c = \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} \times 0.040 \text{ m}/3}{50 \text{ W/m} \cdot \text{K}} = 0.26.$$

Since $Bi_c > 0.1$, lumped capacitance method is not appropriate. Recognize that when $Fo \geq 0.2$, the time dependence of the temperature at any point within the sphere will be the same as the center. Using the Heisler chart method, Figure 5S.8 provides the relation between $T(r_o,t)$ and $T(0,t)$. Find first the Biot number,

$$Bi = \frac{hr_o}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} \times 0.040 \text{ m}}{50 \text{ W/m} \cdot \text{K}} = 0.80.$$

With $Bi^{-1} = 1/0.80 = 1.25$ and $r/r_o = 1$, read from Figure 5S.8,

$$\frac{\theta}{\theta_o} = \frac{T(r_o,t) - T_\infty}{T(0,t) - T_\infty} = 0.67.$$

It follows that

$$T(0,t) = T_\infty + \frac{1}{0.67} [T(r_o,t) - T_\infty] = 50^\circ\text{C} + \frac{1}{0.67} [150 - 50]^\circ\text{C} = 199^\circ\text{C}. \quad <$$

COMMENTS: (1) There is sufficient information to evaluate Fo ; hence, we require that the time be sufficiently long after the start of quenching for this solution to be appropriate.

(2) The approximate series solution could also be used to obtain $T(0,t)$. For $Bi = 0.80$ from Table 5.1, $\zeta_1 = 1.5044$ rad. Substituting numerical values, $r^* = 1$,

$$\frac{\theta^*}{\theta_o^*} = \frac{T(r_o,t) - T_\infty}{T(0,t) - T_\infty} = \frac{1}{\zeta_1 r^*} \sin(\zeta_1 r^*) = \frac{1}{1.5044} \sin(1.5044 \text{ rad}) = 0.663.$$

It follows that $T(0,t) = 201^\circ\text{C}$.

PROBLEM 5S.7

KNOWN: Diameter and initial temperature of hailstone falling through warm air.

FIND: (a) Time, t_m , required for outer surface to reach melting point, $T(r_o, t_m) = T_m = 0^\circ\text{C}$,
(b) Centerpoint temperature at that time, (c) Energy transferred to the stone.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties.

PROPERTIES: Table A-3, Ice (253K): $\rho = 920 \text{ kg/m}^3$, $k = 2.03 \text{ W/m}\cdot\text{K}$, $c_p = 1945 \text{ J/kg}\cdot\text{K}$;
 $\alpha = k/\rho c_p = 1.13 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: (a) Calculate the lumped capacitance Biot number,

$$\text{Bi} = \frac{h(r_o/3)}{k} = \frac{250 \text{ W/m}^2 \cdot \text{K} (0.0025 \text{ m}/3)}{2.03 \text{ W/m}\cdot\text{K}} = 0.103.$$

Since $\text{Bi} > 0.1$, use the Heisler charts for which

$$\frac{\theta(r_o, t_m)}{\theta_i} = \frac{T(r_o, t_m) - T_\infty}{T_i - T_\infty} = \frac{0 - 5}{-30 - 5} = 0.143$$

$$\text{Bi}^{-1} = \frac{k}{hr_o} = \frac{2.03 \text{ W/m}\cdot\text{K}}{250 \text{ W/m}^2 \cdot \text{K} \times 0.0025 \text{ m}} = 3.25.$$

From Figure 5S.8, find $\frac{\theta(r_o, t_m)}{\theta_o(t_m)} \approx 0.86$.

It follows that $\frac{\theta_o(t_m)}{\theta_i} = \frac{\theta(r_o, t_m)/\theta_i}{\theta(r_o, t_m)/\theta_o(t_m)} \approx \frac{0.143}{0.86} \approx 0.17$.

From Figure 5S.7 find $\text{Fo} \approx 2.1$. Hence,

$$t_m \approx \frac{\text{Fo } r_o^2}{\alpha} = \frac{2.1(0.0025)^2}{1.13 \times 10^{-6} \text{ m}^2/\text{s}} = 12 \text{ s.} \quad <$$

(b) Since $(\theta_o/\theta_i) \approx 0.17$, find

$$T_o - T_\infty \approx 0.17(T_i - T_\infty) \approx 0.17(-30 - 5) \approx -6.0^\circ\text{C}$$

$$T_o(t_m) \approx -1.0^\circ\text{C}. \quad <$$

(c) With $\text{Bi}^2 \text{Fo} = (1/3.25)^2 \times 2.1 = 0.2$, from Figure 5S.9, find $Q/Q_o \approx 0.82$. From Equation 5.44,

$$Q_o = \rho V c_p \theta_i = (920 \text{ kg/m}^3) (\pi/6) (0.005 \text{ m})^3 1945 (\text{J/kg}\cdot\text{K}) (-35 \text{ K}) = -4.10 \text{ J}$$

$$Q = 0.82 Q_o = 0.82(-4.10 \text{ J}) = -3.4 \text{ J.} \quad <$$

PROBLEM 5S.8

KNOWN: Properties, initial temperature, and convection conditions associated with cooling of glass beads.

FIND: (a) Time required to achieve a prescribed center temperature, (b) Effect of convection coefficient on center and surface temperature histories.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in r , (2) Constant properties, (3) Negligible radiation, (4) $Bi \geq 0.2$.

ANALYSIS: (a) With $h = 400\text{ W/m}^2\cdot\text{K}$, $Bi \equiv h(r_o/3)/k = 400\text{ W/m}^2\cdot\text{K}(0.0005\text{ m})/1.4\text{ W/m}\cdot\text{K} = 0.143$ and the lumped capacitance method should not be used. Instead, use the Heisler charts for which

$$\frac{\theta_o}{\theta_i} = \frac{T(0, t) - T_{\infty}}{T_i - T_{\infty}} = \frac{80 - 15}{477 - 15} = 0.141$$

$$Bi^{-1} = \frac{k}{hr_o} = \frac{1.4\text{ W/m}\cdot\text{K}}{400\text{ W/m}^2\cdot\text{K} \times 0.0015\text{ m}} = 2.33.$$

From Figure 5S.7, find $Fo \approx 1.8$.

$$t \approx \frac{Fo r_o^2}{\alpha} = \frac{1.8(0.0015)^2}{\left[1.4\text{ W/m}\cdot\text{K} / (2200\text{ kg/m}^3 \times 800\text{ J/kg}\cdot\text{K})\right]} = 5.1\text{ s.}$$

From Figure 5S.8, $\frac{\theta(r_o, t)}{\theta_o} \approx 0.82$.

Hence, the corresponding surface temperature is

$$T(r_o, t) \approx T_{\infty} + 0.82(T_o - T_{\infty}) = 15^{\circ}\text{C} + 0.82(80^{\circ}\text{C} - 15^{\circ}\text{C}) = 68.3^{\circ}\text{C}$$

(b) The effect of h on the surface and center temperatures was determined using the IHT *Transient Conduction Model* for a *Sphere*.

Continued...

PROBLEM 5S.8 (Cont.)

The cooling rate increases with increasing h , particularly from 100 to 400 W/m²·K. The temperature difference between the center and surface decreases with increasing t and, during the early stages of solidification, with decreasing h .

COMMENTS: Temperature gradients in the glass are largest during the early stages of solidification and increase with increasing h . Since thermal stresses increase with increasing temperature gradients, the propensity to induce defects due to crack formation in the glass increases with increasing h . Hence, there is a value of h above which product quality would suffer and the process should not be operated.

PROBLEM 5S.9

KNOWN: Steel (plain carbon) billet of square cross-section initially at a uniform temperature of 30°C is placed in a soaking oven and subjected to a convection heating process with prescribed temperature and convection coefficient.

FIND: Time required for billet center temperature to reach 600°C.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction in x_1 and x_2 directions, (2) Constant properties, (3) Heat transfer to billet is by convection only.

PROPERTIES: Table A-1, Steel, plain carbon ($T = (30+600)^\circ\text{C}/2 = 588\text{K} \approx 600\text{K}$): $\rho = 7854 \text{ kg/m}^3$, $c_p = 559 \text{ J/kg}\cdot\text{K}$, $k = 48.0 \text{ W/m}\cdot\text{K}$, $\alpha = k/\rho c_p = 1.093 \times 10^{-5} \text{ m}^2/\text{s}$.

ANALYSIS: The billet corresponds to Case (e), Figure 5S.11 (infinite rectangular bar). Hence, the temperature distribution is of the form

$$\theta^*(x_1, x_2, t) = P(x_1, t) \times P(x_2, t)$$

where $P(x, t)$ denotes the distribution corresponding to the plane wall. Because of symmetry in the x_1 and x_2 directions, the P functions are identical. Hence,

$$\frac{\theta(0,0,t)}{\theta_1} = \left[\frac{\theta_o(0,t)}{\theta_1} \right]_{\text{Plane wall}}^2 \quad \text{where} \quad \begin{cases} \theta = T - T_\infty \\ \theta_1 = T_i - T_\infty \\ \theta_o = T(0,t) - T_\infty \end{cases} \quad \text{and } L = 0.15\text{m}.$$

Substituting numerical values, find

$$\frac{\theta_o(0,t)}{\theta_1} = \left[\frac{T(0,0,t) - T_\infty}{T_i - T_\infty} \right]^{1/2} = \left[\frac{(600 - 750)^\circ\text{C}}{(30 - 750)^\circ\text{C}} \right]^{1/2} = 0.46.$$

Consider now the Heisler chart for the plane wall, Figure 5S.1. For the values

$$\theta_o^* = \frac{\theta_o}{\theta_1} \approx 0.46 \quad \text{Bi}^{-1} = \frac{k}{hL} = \frac{48.0 \text{ W/m}\cdot\text{K}}{100 \text{ W/m}^2 \cdot \text{K} \times 0.15\text{m}} = 3.2$$

find

$$t^* = \text{Fo} = \frac{\alpha t}{L^2} \approx 3.2.$$

Hence,

$$t = \frac{3.2 L^2}{\alpha} = \frac{3.2 (0.15 \text{ m})^2}{1.093 \times 10^{-5} \text{ m}^2/\text{s}} = 6587 \text{ s} = 1.83 \text{ h}.$$

<

PROBLEM 6.1

KNOWN: Form of the velocity and temperature profiles for flow over a surface.

FIND: Expressions for the friction and convection coefficients.

SCHEMATIC:

ANALYSIS: The shear stress at the wall is

$$\tau_s = \mu \left. \frac{\partial u}{\partial y} \right|_{y=0} = \mu \left[A + 2By - 3Cy^2 \right]_{y=0} = A\mu.$$

Hence, the friction coefficient has the form,

$$C_f = \frac{\tau_s}{\rho u_\infty^2 / 2} = \frac{2A\mu}{\rho u_\infty^2}$$

$$C_f = \frac{2A\nu}{u_\infty^2}.$$

<

The convection coefficient is

$$h = \frac{-k_f (\partial T / \partial y)_{y=0}}{T_s - T_\infty} = \frac{-k_f [E + 2Fy - 3Gy^2]_{y=0}}{D - T_\infty}$$

$$h = \frac{-k_f E}{D - T_\infty}.$$

<

COMMENTS: It is a simple matter to obtain the important surface parameters from knowledge of the corresponding boundary layer profiles. However, it is rarely a simple matter to determine the form of the profile.

PROBLEM 6.2

KNOWN: Surface temperatures of a steel wall and temperature of water flowing over the wall.

FIND: (a) Convection coefficient, (b) Temperature gradient in wall and in water at wall surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in x , (3) Constant properties.

PROPERTIES: Table A-1, Steel Type AISI 1010 ($70^{\circ}\text{C} = 343\text{K}$), $k_s = 61.7 \text{ W/m}\cdot\text{K}$; Table A-6, Water ($32.5^{\circ}\text{C} = 305\text{K}$), $k_f = 0.62 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) Applying an energy balance to the control surface at $x = 0$, it follows that

$$q''_{x,\text{cond}} - q''_{x,\text{conv}} = 0$$

and using the appropriate rate equations,

$$k_s \frac{T_{s,2} - T_{s,1}}{L} = h(T_{s,1} - T_{\infty}).$$

Hence,

$$h = \frac{k_s}{L} \frac{T_{s,2} - T_{s,1}}{T_{s,1} - T_{\infty}} = \frac{61.7 \text{ W/m}\cdot\text{K}}{0.35\text{m}} \frac{60^{\circ}\text{C}}{15^{\circ}\text{C}} = 705 \text{ W/m}^2\cdot\text{K}.$$

(b) The gradient in the wall at the surface is

$$\left(\frac{dT}{dx}\right)_s = -\frac{T_{s,2} - T_{s,1}}{L} = -\frac{60^{\circ}\text{C}}{0.35\text{m}} = -171.4^{\circ}\text{C/m}.$$

In the water at $x = 0$, the definition of h gives

$$\left(\frac{dT}{dx}\right)_{f,x=0} = -\frac{h}{k_f}(T_{s,1} - T_{\infty})$$

$$\left(\frac{dT}{dx}\right)_{f,x=0} = -\frac{705 \text{ W/m}^2\cdot\text{K}}{0.62 \text{ W/m}\cdot\text{K}}(15^{\circ}\text{C}) = -17,056^{\circ}\text{C/m}.$$

COMMENTS: Note the relative magnitudes of the gradients. Why is there such a large difference?

PROBLEM 6.3

KNOWN: Boundary layer temperature distribution.

FIND: Surface heat flux.

SCHEMATIC:

PROPERTIES: Table A-4, Air ($T_s = 300\text{K}$): $k = 0.0263\text{ W/m}\cdot\text{K}$.

ANALYSIS: Applying Fourier's law at $y = 0$, the heat flux is

$$q_s'' = -k \left. \frac{\partial T}{\partial y} \right|_{y=0} = -k (T_\infty - T_s) \left[Pr \frac{u_\infty}{\nu} \right] \exp \left[-Pr \frac{u_\infty y}{\nu} \right] \bigg|_{y=0}$$

$$q_s'' = -k (T_\infty - T_s) Pr \frac{u_\infty}{\nu}$$

$$q_s'' = -0.0263\text{ W/m}\cdot\text{K} (100\text{K}) 0.7 \times 5000\text{ 1/m}.$$

$$q_s'' = -9205\text{ W/m}^2.$$

<

COMMENTS: (1) Negative flux implies convection heat transfer to the surface.

(2) Note use of k at T_s to evaluate q_s'' from Fourier's law.

PROBLEM 6.4

KNOWN: Variation of h_x with x for laminar flow over a flat plate.

FIND: Ratio of average coefficient, \bar{h}_x , to local coefficient, h_x , at x .

SCHEMATIC:

ANALYSIS: The average value of h_x between 0 and x is

$$\begin{aligned}\bar{h}_x &= \frac{1}{x} \int_0^x h_x dx = \frac{C}{x} \int_0^x x^{-1/2} dx \\ \bar{h}_x &= \frac{C}{x} 2x^{1/2} = 2Cx^{-1/2} \\ \bar{h}_x &= 2h_x.\end{aligned}$$

Hence, $\frac{\bar{h}_x}{h_x} = 2.$

<

COMMENTS: Both the local and average coefficients decrease with increasing distance x from the leading edge, as shown in the sketch below.

PROBLEM 6.5

KNOWN: Variation of local convection coefficient with x for free convection from a vertical heated plate.

FIND: Ratio of average to local convection coefficient.

SCHEMATIC:

ANALYSIS: The average coefficient from 0 to x is

$$\bar{h}_x = \frac{1}{x} \int_0^x h_x dx = \frac{C}{x} \int_0^x x^{-1/4} dx$$

$$\bar{h}_x = \frac{4}{3} \frac{C}{x} x^{3/4} = \frac{4}{3} C x^{-1/4} = \frac{4}{3} h_x.$$

Hence, $\frac{\bar{h}_x}{h_x} = \frac{4}{3}.$

<

The variations with distance of the local and average convection coefficients are shown in the sketch.

COMMENTS: Note that $\bar{h}_x / h_x = 4/3$ is independent of x . Hence the average coefficient for an entire plate of length L is $\bar{h}_L = \frac{4}{3} h_L$, where h_L is the local coefficient at $x = L$. Note also that the average *exceeds* the local. Why?

PROBLEM 6.6

KNOWN: Expression for the local heat transfer coefficient of a circular, hot gas jet at T_∞ directed normal to a circular plate at T_s of radius r_o .

FIND: Heat transfer rate to the plate by convection.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Flow is axisymmetric about the plate, (3) For $h(r)$, a and b are constants and $n \neq -2$.

ANALYSIS: The convective heat transfer rate to the plate follows from Newton's law of cooling

$$q_{\text{conv}} = \int_A dq_{\text{conv}} = \int_A h(r) \cdot dA \cdot (T_\infty - T_s).$$

The local heat transfer coefficient is known to have the form,

$$h(r) = a + br^n$$

and the differential area on the plate surface is

$$dA = 2\pi r \, dr.$$

Hence, the heat rate is

$$\begin{aligned} q_{\text{conv}} &= \int_0^{r_o} (a + br^n) \cdot 2\pi r \, dr \cdot (T_\infty - T_s) \\ q_{\text{conv}} &= 2\pi (T_\infty - T_s) \left[\frac{a}{2} r^2 + \frac{b}{n+2} r^{n+2} \right]_0^{r_o} \\ q_{\text{conv}} &= 2\pi \left[\frac{a}{2} r_o^2 + \frac{b}{n+2} r_o^{n+2} \right] (T_\infty - T_s). \end{aligned}$$

<

COMMENTS: Note the importance of the requirement, $n \neq -2$. Typically, the radius of the jet is much smaller than that of the plate.

PROBLEM 6.7

KNOWN: Distribution of local convection coefficient for obstructed parallel flow over a flat plate.

FIND: Average heat transfer coefficient and ratio of average to local at the trailing edge.

SCHEMATIC:

ANALYSIS: The average convection coefficient is

$$\bar{h}_L = \frac{1}{L} \int_0^L h_x dx = \frac{1}{L} \int_0^L (0.7 + 13.6x - 3.4x^2) dx$$

$$\bar{h}_L = \frac{1}{L} (0.7L + 6.8L^2 - 1.13L^3) = 0.7 + 6.8L - 1.13L^2$$

$$\bar{h}_L = 0.7 + 6.8(3) - 1.13(9) = 10.9 \text{ W/m}^2 \cdot \text{K}.$$

<

The local coefficient at $x = 3\text{ m}$ is

$$h_L = 0.7 + 13.6(3) - 3.4(9) = 10.9 \text{ W/m}^2 \cdot \text{K}.$$

Hence,

$$\bar{h}_L / h_L = 1.0.$$

<

COMMENTS: The result $\bar{h}_L / h_L = 1.0$ is unique to $x = 3\text{ m}$ and is a consequence of the existence of a maximum for $h_x(x)$. The maximum occurs at $x = 2\text{ m}$, where

$$(dh_x / dx) = 0 \text{ and } (d^2h_x / dx^2 < 0.)$$

PROBLEM 6.8

KNOWN: Temperature distribution in boundary layer for air flow over a flat plate.

FIND: Variation of local convection coefficient along the plate and value of average coefficient.

SCHEMATIC:

ANALYSIS: From Eq. 6.5,

$$h = -\frac{k \partial T / \partial y|_{y=0}}{(T_s - T_\infty)} = +\frac{k(70 \times 600x)}{(T_s - T_\infty)}$$

where $T_s = T(x, 0) = 90^\circ\text{C}$. Evaluating k at the arithmetic mean of the freestream and surface temperatures, $\bar{T} = (20 + 90)^\circ\text{C}/2 = 55^\circ\text{C} = 328\text{ K}$, Table A.4 yields $k = 0.0284\text{ W/m}\cdot\text{K}$. Hence, with $T_s - T_\infty = 70^\circ\text{C} = 70\text{ K}$,

$$h = \frac{0.0284\text{ W/m}\cdot\text{K}(42,000x)\text{ K/m}}{70\text{ K}} = 17x \left(\text{W/m}^2\cdot\text{K} \right)$$

<

and the convection coefficient increases linearly with x .

The average coefficient over the range $0 \leq x \leq 5\text{ m}$ is

$$\bar{h} = \frac{1}{L} \int_0^L h dx = \frac{17}{5} \int_0^5 x dx = \frac{17}{5} \frac{x^2}{2} \bigg|_0^5 = 42.5\text{ W/m}^2\cdot\text{K}$$

<

PROBLEM 6.9

KNOWN: Variation of local convection coefficient with distance x from a heated plate with a uniform temperature T_s .

FIND: (a) An expression for the average coefficient \bar{h}_{12} for the section of length $(x_2 - x_1)$ in terms of C , x_1 and x_2 , and (b) An expression for \bar{h}_{12} in terms of x_1 and x_2 , and the average coefficients \bar{h}_1 and \bar{h}_2 , corresponding to lengths x_1 and x_2 , respectively.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar flow over a plate with uniform surface temperature, T_s , and (2) Spatial variation of local coefficient is of the form $h_x = Cx^{-1/2}$, where C is a constant.

ANALYSIS: (a) The heat transfer rate per unit width from a longitudinal section, $x_2 - x_1$, can be expressed as

$$q'_{12} = \bar{h}_{12} (x_2 - x_1) (T_s - T_\infty) \quad (1)$$

where \bar{h}_{12} is the average coefficient for the section of length $(x_2 - x_1)$. The heat rate can also be written in terms of the local coefficient, Eq. (6.11), as

$$q'_{12} = \int_{x_1}^{x_2} h_x dx (T_s - T_\infty) = (T_s - T_\infty) \int_{x_1}^{x_2} h_x dx \quad (2)$$

Combining Eq. (1) and (2),

$$\bar{h}_{12} = \frac{1}{(x_2 - x_1)} \int_{x_1}^{x_2} h_x dx \quad (3)$$

and substituting for the form of the local coefficient, $h_x = Cx^{-1/2}$, find that

$$\bar{h}_{12} = \frac{1}{(x_2 - x_1)} \int_{x_1}^{x_2} Cx^{-1/2} dx = \frac{C}{x_2 - x_1} \left[\frac{x^{1/2}}{1/2} \right]_{x_1}^{x_2} = 2C \frac{x_2^{1/2} - x_1^{1/2}}{x_2 - x_1} \quad (4)$$

(b) The heat rate, given as Eq. (1), can also be expressed as

$$q'_{12} = \bar{h}_2 x_2 (T_s - T_\infty) - \bar{h}_1 x_1 (T_s - T_\infty) \quad (5)$$

which is the difference between the heat rate for the plate over the section $(0 - x_2)$ and over the section $(0 - x_1)$. Combining Eqs. (1) and (5), find,

$$\bar{h}_{12} = \frac{\bar{h}_2 x_2 - \bar{h}_1 x_1}{x_2 - x_1} \quad (6)$$

COMMENTS: (1) Note that, from Eq. 6.6,

$$\bar{h}_x = \frac{1}{x} \int_0^x h_x dx = \frac{1}{x} \int_0^x Cx^{-1/2} dx = 2Cx^{-1/2} \quad (7)$$

or $\bar{h}_x = 2h_x$. Substituting Eq. (7) into Eq. (6), see that the result is the same as Eq. (4).

PROBLEM 6.10

KNOWN: Expression for face-averaged Nusselt numbers on a cylinder of rectangular cross section. Dimensions of the cylinder.

FIND: Average heat transfer coefficient over the entire cylinder. Plausible explanation for variations in the face-averaged heat transfer coefficients.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

PROPERTIES: Table A.4, air (300 K): $k = 0.0263 \text{ W/m}\cdot\text{K}$, $\nu = 1.589 \times 10^{-5} \text{ m}^2/\text{s}$, $\text{Pr} = 0.707$.

ANALYSIS:

For the square cylinder, $c/d = 40 \text{ mm}/30 \text{ mm} = 1.33$

$$\text{Re}_d = \frac{Vd}{\nu} = \frac{10 \text{ m/s} \times 30 \times 10^{-3} \text{ m}}{1.589 \times 10^{-5} \text{ m}^2/\text{s}} = 18,880$$

Therefore, for the front face $C = 0.674$, $m = 1/2$. For the sides, $C = 0.107$, $m = 2/3$ while for the back $C = 0.153$, $m = 2/3$.

Front face:

$$\text{Nu}_{d,f} = 0.674 \times 18,880^{1/2} \times 0.707^{1/3} = 82.44$$

$$\bar{h}_f = \frac{k\text{Nu}_d}{d} = \frac{0.0263 \text{ W/m}\cdot\text{K} \times 82.44}{30 \times 10^{-3} \text{ m}} = 72.27 \text{ W/m}^2 \cdot \text{K}$$

Side faces:

$$\text{Nu}_{d,s} = 0.107 \times 18,880^{2/3} \times 0.707^{1/3} = 67.36$$

$$\bar{h}_s = \frac{k\text{Nu}_{d,s}}{d} = \frac{0.0263 \text{ W/m}\cdot\text{K} \times 67.36}{30 \times 10^{-3} \text{ m}} = 59.05 \text{ W/m}^2 \cdot \text{K}$$

Back face:

$$\text{Nu}_{d,b} = 0.153 \times 18,880^{2/3} \times 0.707^{1/3} = 96.43$$

$$\bar{h}_b = \frac{k\text{Nu}_{d,b}}{d} = \frac{0.0263 \text{ W/m}\cdot\text{K} \times 96.43}{30 \times 10^{-3} \text{ m}} = 84.54 \text{ W/m}^2 \cdot \text{K}$$

Continued...

PROBLEM 6.11

KNOWN: Radial distribution of local convection coefficient for flow normal to a circular disk.

FIND: Expression for average Nusselt number.

SCHEMATIC:

ASSUMPTIONS: Constant properties.

ANALYSIS: The average convection coefficient is

$$\begin{aligned}\bar{h} &= \frac{1}{A_s} \int_{A_s} h dA_s \\ \bar{h} &= \frac{1}{\pi r_o^2} \int_0^{r_o} \frac{k}{D} \text{Nu}_o \left[1 + a \left(\frac{r}{r_o} \right)^n \right] 2\pi r dr \\ \bar{h} &= \frac{k \text{Nu}_o}{r_o^3} \left[\frac{r^2}{2} + \frac{a r^{n+2}}{(n+2)r_o^n} \right]_0^{r_o}\end{aligned}$$

where Nu_o is the Nusselt number at the stagnation point ($r = 0$). Hence,

$$\begin{aligned}\overline{\text{Nu}}_D &= \frac{\bar{h}D}{k} = 2\text{Nu}_o \left[\frac{(r/r_o)^2}{2} + \frac{a}{(n+2)} \left(\frac{r}{r_o} \right)^{n+2} \right]_0^{r_o} \\ \overline{\text{Nu}}_D &= \text{Nu}_o \left[1 + \frac{2a}{(n+2)} \right] \\ \overline{\text{Nu}}_D &= \left[1 + \frac{2a}{(n+2)} \right] 0.814 \text{Re}_D^{1/2} \text{Pr}^{0.36}.\end{aligned}$$

<

COMMENTS: The increase in $h(r)$ with r may be explained in terms of the sharp turn which the boundary layer flow must make around the edge of the disk. The boundary layer accelerates and its thickness decreases as it makes the turn, causing the local convection coefficient to increase.

PROBLEM 6.12

KNOWN: Convection correlation and temperature of an impinging air jet. Dimensions and initial temperature of a heated copper disk. Properties of the air and copper.

FIND: Effect of jet velocity on temperature decay of disk following jet impingement.

SCHEMATIC:

ASSUMPTIONS: (1) Validity of lumped capacitance analysis, (2) Negligible heat transfer from sides and bottom of disk, (3) Constant properties.

ANALYSIS: Performing an energy balance on the disk, it follows that

$$\dot{E}_{st} = \rho V c \frac{dT}{dt} = -A_s (q''_{\text{conv}} + q''_{\text{rad}}). \text{ Hence, with } V = A_s L,$$

$$\frac{dT}{dt} = - \frac{\bar{h}(T - T_{\infty}) + h_r(T - T_{\text{sur}})}{\rho c L}$$

where, $h_r = \epsilon \sigma (T + T_{\text{sur}})(T^2 + T_{\text{sur}}^2)$ and, from the solution to Problem 6.11,

$$\bar{h} = \frac{k}{D} \overline{\text{Nu}}_D = \frac{k}{D} \left(1 + \frac{2a}{n+2} \right) 0.814 \text{Re}_D^{1/2} \text{Pr}^{0.36}$$

With $a = 0.30$ and $n = 2$, it follows that

$$\bar{h} = (k/D) 0.936 \text{Re}_D^{1/2} \text{Pr}^{0.36}$$

where $\text{Re}_D = VD/\nu$. Using the *Lumped Capacitance Model* of IHT, the following temperature histories were determined.

Continued

PROBLEM 6.12 (Cont.)

The temperature decay becomes more pronounced with increasing V , and a final temperature of 400 K is reached at $t = 2760$, 1455 and 976s for $V = 4$, 20 and 50 m/s, respectively.

COMMENTS: The maximum Biot number, $Bi = (\bar{h} + h_r)L/k_{Cu}$, is associated with $V = 50 \text{ m/s}$ (maximum \bar{h} of $169 \text{ W/m}^2\cdot\text{K}$) and $t = 0$ (maximum h_r of $64 \text{ W/m}^2\cdot\text{K}$), in which case the maximum Biot number is $Bi = (233 \text{ W/m}^2\cdot\text{K})(0.025 \text{ m})/(386 \text{ W/m}\cdot\text{K}) = 0.015 < 0.1$. Hence, the lumped capacitance approximation is valid.

PROBLEM 6.13

KNOWN: Local convection coefficient on rotating disk. Radius and surface temperature of disk. Temperature of stagnant air.

FIND: Local heat flux and total heat rate. Nature of boundary layer.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat transfer from back surface and edge of disk.

ANALYSIS: If the local convection coefficient is independent of radius, the local heat flux at every point on the disk is

$$q'' = h(T_s - T_\infty) = 20 \text{ W/m}^2 \cdot \text{K} (50 - 20)^\circ\text{C} = 600 \text{ W/m}^2 \quad <$$

Since h is independent of location, $\bar{h} = h = 20 \text{ W/m}^2 \cdot \text{K}$ and the total power requirement is

$$P_{\text{elec}} = q = \bar{h}A_s(T_s - T_\infty) = \bar{h}\pi r_o^2(T_s - T_\infty)$$

$$P_{\text{elec}} = (20 \text{ W/m}^2 \cdot \text{K}) \pi (0.1 \text{ m})^2 (50 - 20)^\circ\text{C} = 18.9 \text{ W} \quad <$$

If the convection coefficient is independent of radius, the boundary layer must be of uniform thickness δ . Within the boundary layer, air flow is principally in the circumferential direction. The circumferential velocity component u_θ corresponds to the rotational velocity of the disk at the surface ($y = 0$) and increases with increasing r ($u_\theta = \Omega r$). The velocity decreases with increasing distance y from the surface, approaching zero at the outer edge of the boundary layer ($y \rightarrow \delta$).

PROBLEM 6.14

KNOWN: Air flow over a flat plate of known length, location of transition from laminar to turbulent flow, value of the critical Reynolds number.

FIND: (a) Free stream velocity with properties evaluated at $T = 350$ K, (b) Expression for the average convection coefficient, $\bar{h}_{\text{lam}}(x)$, as a function of the distance x from the leading edge in the laminar region, (c) Expression for the average convection coefficient $\bar{h}_{\text{turb}}(x)$, as a function of the distance x from the leading edge in the turbulent region, (d) Compute and plot the local and average convection coefficients over the entire plate length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

PROPERTIES: Table A.4, air ($T = 350$ K): $k = 0.030$ W/m·K, $\nu = 20.92 \times 10^{-6}$ m²/s, $Pr = 0.700$.

ANALYSIS:

(a) Using air properties evaluated at 350 K with $x_c = 0.5$ m,

$$Re_{x,c} = \frac{u_{\infty} x_c}{\nu} = 5 \times 10^5$$

$$u_{\infty} = 5 \times 10^5 \nu / x_c = 5 \times 10^5 \times 20.92 \times 10^{-6} \text{ m}^2/\text{s} / 0.5 \text{ m} = 20.9 \text{ m/s} \quad <$$

(b) From Eq. 6.13, the average coefficient in the laminar region, $0 \leq x \leq x_c$, is

$$\bar{h}_{\text{lam}}(x) = \frac{1}{x} \int_0^x h_{\text{lam}}(x) dx = \frac{1}{x} C_{\text{lam}} \int_0^x x^{-0.5} dx = \frac{1}{x} C_{\text{lam}} x^{0.5} = 2 C_{\text{lam}} x^{-0.5} = 2 h_{\text{lam}}(x) \quad (1) \quad <$$

(c) The average coefficient in the turbulent region, $x_c \leq x \leq L$, is

$$\bar{h}_{\text{turb}}(x) = \frac{1}{x} \left[\int_0^{x_c} h_{\text{lam}}(x) dx + \int_{x_c}^x h_{\text{turb}}(x) dx \right] = \left[C_{\text{lam}} \frac{x^{0.5}}{0.5} \right]_0^{x_c} + C_{\text{turb}} \left[\frac{x^{0.8}}{0.8} \right]_{x_c}^x$$

Continued...

PROBLEM 6.14 (Cont.)

$$\bar{h}_{\text{turb}}(x) = \frac{1}{x} \left[2C_{\text{lam}} x_c^{0.5} + 1.25C_{\text{turb}} \left(x^{0.8} - x_c^{0.8} \right) \right] \quad (2) <$$

(d) The local and average coefficients, Eqs. (1) and (2) are plotted below as a function of x for the range $0 \leq x \leq L$.

PROBLEM 6.15

KNOWN: Air speed and temperature in a wind tunnel.

FIND: (a) Minimum plate length to achieve a Reynolds number of 10^8 , (b) Distance from leading edge at which transition would occur.

SCHEMATIC:

ASSUMPTIONS: (1) Isothermal conditions, $T_s = T_\infty$.

PROPERTIES: Table A-4, Air ($25^\circ\text{C} = 298\text{K}$): $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: (a) The Reynolds number is

$$\text{Re}_x = \frac{\rho u_\infty x}{\mu} = \frac{u_\infty x}{\nu}.$$

To achieve a Reynolds number of 1×10^8 , the minimum plate length is then

$$L_{\min} = \frac{\text{Re}_x \nu}{u_\infty} = \frac{1 \times 10^8 (15.71 \times 10^{-6} \text{ m}^2/\text{s})}{50 \text{ m/s}}$$

$$L_{\min} = 31.4 \text{ m.}$$

<

(b) For a transition Reynolds number of 5×10^5

$$x_c = \frac{\text{Re}_{x,c} \nu}{u_\infty} = \frac{5 \times 10^5 (15.71 \times 10^{-6} \text{ m}^2/\text{s})}{50 \text{ m/s}}$$

$$x_c = 0.157 \text{ m.}$$

<

COMMENTS: Note that

$$\frac{x_c}{L} = \frac{\text{Re}_{x,c}}{\text{Re}_L}$$

This expression may be used to quickly establish the location of transition from knowledge of $\text{Re}_{x,c}$ and Re_L .

PROBLEM 6.16

KNOWN: Transition Reynolds number. Velocity and temperature of atmospheric air, engine oil, and mercury flow over a flat plate.

FIND: Distance from leading edge at which transition occurs for each fluid.

SCHEMATIC:

ASSUMPTIONS: Transition Reynolds number is $\text{Re}_{x,c} = 5 \times 10^5$.

PROPERTIES: For the fluids at $T = 300 \text{ K}$ and 350 K :

Fluid	Table	$\nu (\text{m}^2/\text{s})$	
		$T = 300 \text{ K}$	$T = 350 \text{ K}$
Air (1 atm)	A-4	15.89×10^{-6}	20.92×10^{-6}
Engine Oil	A-5	550×10^{-6}	41.7×10^{-6}
Mercury	A-5	0.1125×10^{-6}	0.0976×10^{-6}

ANALYSIS: The point of transition is

$$x_c = \text{Re}_{x,c} \frac{\nu}{u_\infty} = \frac{5 \times 10^5}{1 \text{ m/s}} \nu.$$

Substituting appropriate viscosities, find

Fluid	$x_c (\text{m})$	
	$T = 300 \text{ K}$	$T = 350 \text{ K}$
Air	7.95	10.5
Oil	275	20.9
Mercury	0.056	0.049

<

COMMENTS: (1) Note the great disparity in transition length for the different fluids. Due to the effect which viscous forces have on attenuating the instabilities which bring about transition, the distance required to achieve transition increases with increasing ν . (2) Note the temperature-dependence of the transition length, in particular for engine oil. (3) As shown in Example 6.4, the variation of the transition location can have a significant effect on the average heat transfer coefficient associated with convection to or from the plate.

PROBLEM 6.17

KNOWN: Pressure dependence of the dynamic viscosity, thermal conductivity and specific heat.

FIND: (a) Variation of the kinematic viscosity and thermal diffusivity with pressure for an incompressible liquid and an ideal gas, (b) Value of the thermal diffusivity of air at 350 K for pressures of 1, 5 and 10 atm, (c) Location where transition occurs for air flow over a flat plate with $T_\infty = 350$ K, $p = 1, 5$ and 10 atm, and $u_\infty = 2$ m/s.

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Transition at $Re_{x,c} = 5 \times 10^5$, (4) Ideal gas behavior.

PROPERTIES: Table A.4, air (350 K): $\mu = 208.2 \times 10^{-7}$ N·s/m², $k = 0.030$ W/m·K, $c_p = 1009$ J/kg·K, $\rho = 0.995$ kg/m³.

ANALYSIS:

(a) For an ideal gas

$$p = \rho RT \text{ or } \rho = p/RT \quad (1)$$

while for an incompressible liquid, $\rho = \text{constant}$ (2)

The kinematic viscosity is $\nu = \mu/\rho$ (3)

Therefore, for an ideal gas

$$\nu = \mu RT/p \text{ or } \nu \propto p^{-1} \quad (4) \quad <$$

and for an incompressible liquid

$$\nu = \mu/\rho \text{ or } \nu \text{ is independent of pressure.} \quad <$$

The thermal diffusivity is

$$\alpha = k/\rho c$$

Therefore, for an ideal gas,

$$\alpha = kRT/pc \text{ or } \alpha \propto p^{-1} \quad (6) \quad <$$

For an incompressible liquid $\alpha = k/\rho c$ or α is independent of pressure <

(b) For $T = 350$ K, $p = 1$ atm, the thermal diffusivity of air is

$$\alpha = \frac{0.030 \text{ W/m} \cdot \text{K}}{0.995 \text{ kg/m}^3 \times 1009 \text{ J/kg} \cdot \text{K}} = 29.9 \times 10^{-6} \text{ m}^2/\text{s} \quad <$$

Using Equation 6, at $p = 5$ atm,

Continued...

PROBLEM 6.17 (Cont.)

$$\alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}/5 = 5.98 \times 10^{-6} \text{ m}^2/\text{s} \quad <$$

At $p = 10 \text{ atm}$,

$$\alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}/10 = 2.99 \times 10^{-6} \text{ m}^2/\text{s} \quad <$$

(c) For transition over a flat plate,

$$\text{Re}_{x,c} = \frac{x_c u_\infty}{\nu} = 5 \times 10^5$$

Therefore

$$x_c = 5 \times 10^5 (\nu/u_\infty)$$

For $T_\infty = 350 \text{ K}$, $p = 1 \text{ atm}$,

$$\nu = \mu/\rho = 208.2 \times 10^{-7} \text{ N} \cdot \text{s}/\text{m}^2 / 0.995 \text{ kg}/\text{m}^3 = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$$

Using Equation 4, at $p = 5 \text{ atm}$

$$\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}/5 = 4.18 \times 10^{-6} \text{ m}^2/\text{s}$$

At $p = 10 \text{ atm}$,

$$\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}/10 = 2.09 \times 10^{-6} \text{ m}^2/\text{s}$$

Therefore, at $p = 1 \text{ atm}$

$$x_c = 5 \times 10^5 \times 20.92 \times 10^{-6} \text{ m}^2/\text{s}/(2 \text{ m}/\text{s}) = 5.23 \text{ m} \quad <$$

At $p = 5 \text{ atm}$,

$$x_c = 5 \times 10^5 \times 4.18 \times 10^{-6} \text{ m}^2/\text{s}/(2 \text{ m}/\text{s}) = 1.05 \text{ m} \quad <$$

At $p = 10 \text{ atm}$

$$x_c = 5 \times 10^5 \times 2.09 \times 10^{-6} \text{ m}^2/\text{s}/(2 \text{ m}/\text{s}) = 0.523 \text{ m} \quad <$$

COMMENT: Note the strong dependence of the transition length upon the pressure for the gas (the transition length is independent of pressure for the incompressible liquid).

PROBLEM 6.18

KNOWN: Characteristic length, surface temperature and average heat flux for an object placed in an airstream of prescribed temperature and velocity.

FIND: Average convection coefficient if characteristic length of object is increased by a factor of five and air velocity is decreased by a factor of five.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

ANALYSIS: For a particular geometry,

$$\overline{\text{Nu}}_L = f(\text{Re}_L, \text{Pr}).$$

The Reynolds numbers for each case are

$$\text{Case 1:} \quad \text{Re}_{L,1} = \frac{V_1 L_1}{\nu_1} = \frac{(100 \text{ m/s}) (1 \text{ m})}{\nu_1} = \frac{100 \text{ m}^2/\text{s}}{\nu_1}$$

$$\text{Case 2:} \quad \text{Re}_{L,2} = \frac{V_2 L_2}{\nu_2} = \frac{(20 \text{ m/s}) (5 \text{ m})}{\nu_2} = \frac{100 \text{ m}^2/\text{s}}{\nu_2}.$$

Hence, with $\nu_1 = \nu_2$, $\text{Re}_{L,1} = \text{Re}_{L,2}$. Since $\text{Pr}_1 = \text{Pr}_2$, it follows that

$$\overline{\text{Nu}}_{L,2} = \overline{\text{Nu}}_{L,1}.$$

Hence,

$$\begin{aligned} \overline{h}_2 L_2 / k_2 &= \overline{h}_1 L_1 / k_1 \\ \overline{h}_2 &= \overline{h}_1 \frac{L_1}{L_2} = 0.2 \overline{h}_1. \end{aligned}$$

For *Case 1*, using the rate equation, the convection coefficient is

$$\begin{aligned} q_1 &= \overline{h}_1 A_1 (T_s - T_\infty)_1 \\ \overline{h}_1 &= \frac{(q_1 / A_1)}{(T_s - T_\infty)_1} = \frac{q_1''}{(T_s - T_\infty)_1} = \frac{20,000 \text{ W/m}^2}{(400 - 300) \text{ K}} = 200 \text{ W/m}^2 \cdot \text{K}. \end{aligned}$$

Hence, it follows that for *Case 2*

$$\overline{h}_2 = 0.2 \times 200 \text{ W/m}^2 \cdot \text{K} = 40 \text{ W/m}^2 \cdot \text{K}.$$

<

COMMENTS: If $\text{Re}_{L,2}$ were *not* equal to $\text{Re}_{L,1}$, it would be necessary to know the specific form of $f(\text{Re}_L, \text{Pr})$ before \overline{h}_2 could be determined.

PROBLEM 6.19

KNOWN: Heat transfer rate from a turbine blade for prescribed operating conditions.

FIND: Heat transfer rate from a larger blade operating under different conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Surface area A is directly proportional to characteristic length L , (4) Negligible radiation, (5) Blade shapes are geometrically similar.

ANALYSIS: For a prescribed geometry,

$$\overline{Nu} = \frac{\bar{h}L}{k} = f(\text{Re}_L, \text{Pr}).$$

The Reynolds numbers for the blades are

$$\text{Re}_{L,1} = (V_1 L_1 / \nu) = 15 / \nu \quad \text{Re}_{L,2} = (V_2 L_2 / \nu) = 15 / \nu.$$

Hence, with constant properties, $\text{Re}_{L,1} = \text{Re}_{L,2}$. Also, $\text{Pr}_1 = \text{Pr}_2$. Therefore,

$$\begin{aligned} \overline{Nu}_2 &= \overline{Nu}_1 \\ (\bar{h}_2 L_2 / k) &= (\bar{h}_1 L_1 / k) \\ \bar{h}_2 &= \frac{L_1}{L_2} \bar{h}_1 = \frac{L_1}{L_2} \frac{q_1}{A_1 (T_{s,1} - T_\infty)}. \end{aligned}$$

Hence, the heat rate for the *second blade* is

$$\begin{aligned} q_2 &= \bar{h}_2 A_2 (T_{s,2} - T_\infty) = \frac{L_1}{L_2} \frac{A_2}{A_1} \frac{(T_{s,2} - T_\infty)}{(T_{s,1} - T_\infty)} q_1 \\ q_2 &= \frac{T_{s,2} - T_\infty}{T_{s,1} - T_\infty} q_1 = \frac{(400 - 35)}{(300 - 35)} (1500 \text{ W}) \end{aligned}$$

$$q_2 = 2066 \text{ W}.$$

<

COMMENTS: The slight variation of ν from Case 1 to Case 2 would cause $\text{Re}_{L,2}$ to differ from $\text{Re}_{L,1}$. However, for the prescribed conditions, this non-constant property effect is small.

PROBLEM 6.20

KNOWN: Experimental measurements of the heat transfer coefficient for a square bar in cross flow.

FIND: (a) \bar{h} for the condition when $L = 1\text{m}$ and $V = 15\text{m/s}$, (b) \bar{h} for the condition when $L = 1\text{m}$ and $V = 30\text{m/s}$, (c) Effect of defining a side as the characteristic length.

SCHEMATIC:

ASSUMPTIONS: (1) Functional form $\overline{\text{Nu}} = C\text{Re}^m\text{Pr}^n$ applies with C , m , n being constants, (2) Constant properties.

ANALYSIS: (a) For the experiments and the condition $L = 1\text{m}$ and $V = 15\text{m/s}$, it follows that Pr as well as C , m , and n are constants. Hence

$$\bar{h}L \propto (VL)^m.$$

Using the experimental results, find m . Substituting values

$$\frac{\bar{h}_1 L_1}{\bar{h}_2 L_2} = \left[\frac{V_1 L_1}{V_2 L_2} \right]^m \quad \frac{50 \times 0.5}{40 \times 0.5} = \left[\frac{20 \times 0.5}{15 \times 0.5} \right]^m$$

giving $m = 0.782$. It follows then for $L = 1\text{m}$ and $V = 15\text{m/s}$,

$$\bar{h} = \bar{h}_1 \frac{L_1}{L} \left[\frac{V \cdot L}{V_1 \cdot L_1} \right]^m = 50 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times \frac{0.5}{1.0} \left[\frac{15 \times 1.0}{20 \times 0.5} \right]^{0.782} = 34.3 \text{W/m}^2 \cdot \text{K}. \quad <$$

(b) For the condition $L = 1\text{m}$ and $V = 30\text{m/s}$, find

$$\bar{h} = \bar{h}_1 \frac{L_1}{L} \left[\frac{V \cdot L}{V_1 \cdot L_1} \right]^m = 50 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times \frac{0.5}{1.0} \left[\frac{30 \times 1.0}{20 \times 0.5} \right]^{0.782} = 59.0 \text{W/m}^2 \cdot \text{K}. \quad <$$

(c) If the characteristic length were chosen as a side rather than the diagonal, the value of C would change. However, the coefficients m and n would not change.

COMMENTS: The foregoing Nusselt number relation is used frequently in heat transfer analysis, providing appropriate scaling for the effects of length, velocity, and fluid properties on the heat transfer coefficient.

PROBLEM 6.21

KNOWN: Local Nusselt number correlation for flow over a roughened surface.

FIND: Ratio of average heat transfer coefficient to local coefficient.

SCHEMATIC:

ANALYSIS: The local convection coefficient is obtained from the prescribed correlation,

$$h_x = Nu_x \frac{k}{x} = 0.04 \frac{k}{x} Re_x^{0.9} Pr^{1/3}$$

$$h_x = 0.04 k \left[\frac{V}{\nu} \right]^{0.9} Pr^{1/3} \frac{x^{0.9}}{x} \equiv C_1 x^{-0.1}.$$

To determine the average heat transfer coefficient for the length zero to x ,

$$\bar{h}_x \equiv \frac{1}{x} \int_0^x h_x dx = \frac{1}{x} C_1 \int_0^x x^{-0.1} dx$$

$$\bar{h}_x = \frac{C_1}{x} \frac{x^{0.9}}{0.9} = 1.11 C_1 x^{-0.1}.$$

Hence, the ratio of the average to local coefficient is

$$\frac{\bar{h}_x}{h_x} = \frac{1.11 C_1 x^{-0.1}}{C_1 x^{-0.1}} = 1.11.$$

<

COMMENTS: Note that \bar{Nu}_x / Nu_x is also equal to 1.11. Note, however, that

$$\bar{Nu}_x \neq \frac{1}{x} \int_0^x Nu_x dx.$$

PROBLEM 6.22

KNOWN: Freestream velocity and average convection heat transfer associated with fluid flow over a surface of prescribed characteristic length.

FIND: Values of \overline{Nu}_L , Re_L , Pr , \bar{j}_H for (a) air, (b) engine oil, (c) mercury, (d) water.

SCHEMATIC:

PROPERTIES: For the fluids at 300K:

Fluid	Table	$\nu(m^2/s)$	$k(W/m \cdot K)$	$\alpha(m^2/s)$	Pr
Air	A.4	15.89×10^{-6}	0.0263	22.5×10^{-7}	0.71
Engine Oil	A.5	550×10^{-6}	0.145	0.859×10^{-7}	6400
Mercury	A.5	0.113×10^{-6}	8.54	45.30×10^{-7}	0.025
Water	A.6	0.858×10^{-6}	0.613	1.47×10^{-7}	5.83

ANALYSIS: The appropriate relations required are

$$\overline{Nu}_L = \frac{\bar{h}L}{k} \quad Re_L = \frac{VL}{\nu} \quad Pr = \frac{\nu}{\alpha} \quad j_H = \bar{St}Pr^{2/3} \quad \bar{St} = \frac{\overline{Nu}_L}{Re_L Pr}$$

Fluid	\overline{Nu}_L	Re_L	Pr	\bar{j}_H	<
Air	3802	6.29×10^4	0.71	0.068	
Engine Oil	690	1.82×10^3	6403	0.0204	
Mercury	11.7	8.85×10^6	0.025	4.52×10^{-6}	
Water	163	1.17×10^6	5.84	7.74×10^{-5}	

COMMENTS: Note the wide range of Pr associated with the fluids.

PROBLEM 6.23

KNOWN: Variation of h_x with x for flow over a flat plate.

FIND: Ratio of average Nusselt number for the entire plate to the local Nusselt number at $x = L$.

SCHEMATIC:

ANALYSIS: The expressions for the local and average Nusselt numbers are

$$Nu_L = \frac{h_L L}{k} = \frac{(CL^{-1/2})L}{k} = \frac{CL^{1/2}}{k}$$

$$\overline{Nu}_L = \frac{\overline{h}_L L}{k}$$

where

$$\overline{h}_L = \frac{1}{L} \int_0^L h_x dx = \frac{C}{L} \int_0^L x^{-1/2} dx = \frac{2C}{L} L^{1/2} = 2 CL^{-1/2}.$$

Hence,

$$\overline{Nu}_L = \frac{2 CL^{-1/2} (L)}{k} = \frac{2 CL^{1/2}}{k}$$

and

$$\frac{\overline{Nu}_L}{Nu_L} = 2.$$

COMMENTS: Note the manner in which \overline{Nu}_L is defined in terms of \overline{h}_L . Also note that

$$\overline{Nu}_L \neq \frac{1}{L} \int_0^L Nu_x dx.$$

PROBLEM 6.24

KNOWN: Laminar boundary layer flow of air at 20°C and 1 atm having $\delta_t = 1.13 \delta$.

FIND: Ratio δ / δ_t when fluid is ethylene glycol for same conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar flow.

PROPERTIES: Table A-4, Air (293K, 1 atm): $Pr = 0.709$; Table A-5, Ethylene glycol (293K): $Pr = 211$.

ANALYSIS: The Prandtl number strongly influences relative growth of the velocity, δ , and thermal, δ_t , boundary layers. For laminar flow, the approximate relationship is given by

$$Pr^n \approx \frac{\delta}{\delta_t}$$

where n is a positive coefficient. Substituting the values for air

$$(0.709)^n = \frac{1}{1.13}$$

find that $n = 0.355$. Hence, for ethylene glycol it follows that

$$\frac{\delta}{\delta_t} = Pr^{0.355} = 211^{0.355} = 6.69.$$

<

COMMENTS: (1) For laminar flow, generally we find $n = 0.33$. In which case, $\delta / \delta_t = 5.85$.

(2) Recognize the physical importance of $\nu > \alpha$, which gives large values of the Prandtl number, and causes $\delta > \delta_t$.

PROBLEM 6.25

KNOWN: Air, water, engine oil or mercury at 300K in laminar, parallel flow over a flat plate.

FIND: Sketch of velocity and thermal boundary layer thickness.

ASSUMPTIONS: (1) Laminar flow.

PROPERTIES: For the fluids at 300K:

Fluid	Table	Pr
Air	A.4	0.71
Water	A.6	5.83
Engine Oil	A.5	6400
Mercury	A.5	0.025

ANALYSIS: For laminar, boundary layer flow over a flat plate.

$$\frac{\delta}{\delta_t} \sim \text{Pr}^n$$

where $n > 0$. Hence, the boundary layers appear as shown below.

Air:

Water:

Engine Oil:

Mercury:

COMMENTS: Although Pr strongly influences relative boundary layer development in laminar flow, its influence is weak for turbulent flow.

PROBLEM 6.26

KNOWN: Expression for the local heat transfer coefficient of air at prescribed velocity and temperature flowing over electronic elements on a circuit board and heat dissipation rate for a 4×4 mm chip located 120mm from the leading edge.

FIND: Surface temperature of the chip surface, T_s .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Power dissipated within chip is lost by convection across the upper surface only, (3) Chip surface is isothermal, (4) The average heat transfer coefficient for the chip surface is equivalent to the local value at $x = L$, (5) Negligible radiation.

PROPERTIES: Table A-4, Air (assume $T_s = 45^\circ\text{C}$, $T_f = (45 + 25)/2 = 35^\circ\text{C} = 308\text{K}$, 1atm): $\nu = 16.69 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 26.9 \times 10^{-3} \text{ W/m}\cdot\text{K}$, $Pr = 0.703$.

ANALYSIS: From an energy balance on the chip (see above),

$$q_{\text{conv}} = \dot{E}_g = 30 \text{ W}. \quad (1)$$

Newton's law of cooling for the upper chip surface can be written as

$$T_s = T_\infty + q_{\text{conv}} / \bar{h} A_{\text{chip}} \quad (2)$$

where $A_{\text{chip}} = \ell^2$. Assume that the *average* heat transfer coefficient (\bar{h}) over the chip surface is equivalent to the *local* coefficient evaluated at $x = L$. That is, $\bar{h}_{\text{chip}} \approx h_x(L)$ where the local coefficient can be evaluated from the special correlation for this situation,

$$Nu_x = \frac{h_x x}{k} = 0.04 \left[\frac{Vx}{\nu} \right]^{0.85} Pr^{1/3}$$

and substituting numerical values with $x = L$, find

$$h_x = 0.04 \frac{k}{L} \left[\frac{VL}{\nu} \right]^{0.85} Pr^{1/3}$$

$$h_x = 0.04 \left[\frac{0.0269 \text{ W/m}\cdot\text{K}}{0.120 \text{ m}} \right] \left[\frac{10 \text{ m/s} \times 0.120 \text{ m}}{16.69 \times 10^{-6} \text{ m}^2/\text{s}} \right]^{0.85} (0.703)^{1/3} = 107 \text{ W/m}^2 \cdot \text{K}.$$

The surface temperature of the chip is from Eq. (2),

$$T_s = 25^\circ\text{C} + 30 \times 10^{-3} \text{ W} / \left[107 \text{ W/m}^2 \cdot \text{K} \times (0.004 \text{ m})^2 \right] = 42.5^\circ\text{C}. \quad <$$

COMMENTS: (1) Note that the estimated value for T_f used to evaluate the air properties was reasonable. (2) Alternatively, we could have evaluated \bar{h}_{chip} by performing the integration of the local value, $h(x)$.

PROBLEM 6.27

KNOWN: Expression for the local heat transfer coefficient of air at prescribed velocity and temperature flowing over electronic elements on a circuit board and heat dissipation rate for a 4×4 mm chip located 120 mm from the leading edge. Atmospheric pressure in Mexico City.

FIND: (a) Surface temperature of chip, (b) Air velocity required for chip temperature to be the same at sea level.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Power dissipated in chip is lost by convection across the upper surface only, (3) Chip surface is isothermal, (4) The average heat transfer coefficient for the chip surface is equivalent to the local value at $x = L$, (5) Negligible radiation, (6) Ideal gas behavior.

PROPERTIES: Table A.4, air ($p = 1$ atm, assume $T_s = 45^\circ\text{C}$, $T_f = (45^\circ\text{C} + 25^\circ\text{C})/2 = 35^\circ\text{C}$): $k = 0.0269$ W/m·K, $\nu = 16.69 \times 10^{-6}$ m²/s, $Pr = 0.706$.

ANALYSIS:

(a) From an energy balance on the chip (see above),

$$q_{\text{conv}} = \dot{E}_g = 30\text{W}. \quad (1)$$

Newton's law of cooling for the upper chip surface can be written as

$$T_s = T_\infty + q_{\text{conv}} / \bar{h} A_{\text{chip}} \quad (2)$$

where $A_{\text{chip}} = \ell^2$. From Assumption 4, $\bar{h}_{\text{chip}} \approx h_x(L)$ where the local coefficient can be evaluated from the correlation provided in Problem 6.35.

$$Nu_x = \frac{h_x x}{k} = 0.04 \left[\frac{Vx}{\nu} \right]^{0.85} Pr^{1/3} \quad (3)$$

The kinematic viscosity is

$$\nu = \frac{\mu}{\rho} \quad (4)$$

while for an ideal gas,

$$\rho = \frac{p}{RT} \quad (5)$$

Combining Equations 4 and 5 yields

$$\nu \propto p^{-1} \quad (6)$$

Continued...

PROBLEM 6.27 (Cont.)

The Prandtl number is

$$\text{Pr} = \frac{\nu}{\alpha} = \frac{\mu \rho c}{\rho k} = \frac{\mu c}{k} \quad (7)$$

which is independent of pressure.

Therefore, at sea level ($p = 1 \text{ atm}$)

$$k = 0.0269 \text{ W/m} \cdot \text{K}, \quad \nu = 16.69 \times 10^{-6} \text{ m}^2/\text{s}, \quad \text{Pr} = 0.706$$

$$h_x = 0.04 \frac{k}{L} \left[\frac{VL}{\nu} \right]^{0.85} \text{Pr}^{1/3}$$

$$h_x = 0.04 \left[\frac{0.0269 \text{ W/m} \cdot \text{K}}{0.120 \text{ m}} \right] \left[\frac{10 \text{ m/s} \times 0.120 \text{ m}}{16.69 \times 10^{-6} \text{ m}^2/\text{s}} \right]^{0.85} (0.706)^{1/3} = 107 \text{ W/m}^2 \cdot \text{K}$$

$$T_s = 25^\circ\text{C} + \frac{30 \times 10^{-3} \text{ W}}{107 \text{ W/m}^2 \cdot \text{K} \times (0.004 \text{ m})^2} = 42.5^\circ\text{C}$$

In Mexico City ($p = 76.5 \text{ kPa}$)

$$\nu = 16.69 \times 10^{-6} \text{ m}^2/\text{s} \times \left[\frac{101.3 \text{ kPa}}{76.5 \text{ kPa}} \right] = 22.10 \times 10^{-6} \text{ m}^2/\text{s}$$

$$k = 0.0269 \text{ W/m} \cdot \text{K}, \quad \text{Pr} = 0.706$$

$$h_x = 0.04 \left[\frac{0.0269 \text{ W/m} \cdot \text{K}}{0.120 \text{ m}} \right] \left[\frac{10 \text{ m/s} \times 0.120 \text{ m}}{22.10 \times 10^{-6} \text{ m}^2/\text{s}} \right]^{0.85} (0.706)^{1/3} = 84.5 \text{ W/m}^2 \cdot \text{K}$$

$$T_s = 25^\circ\text{C} + \frac{30 \times 10^{-3} \text{ W}}{84.5 \text{ W/m}^2 \cdot \text{K} \times (0.004 \text{ m})^2} = 47.2^\circ\text{C} \quad <$$

(b) For the same chip temperature, it is required that $h_x = 107 \text{ W/m}^2 \cdot \text{K}$. Therefore

$$h_x = 107 \text{ W/m}^2 \cdot \text{K} = 0.04 \left[\frac{0.0269 \text{ W/m} \cdot \text{K}}{0.120 \text{ m}} \right] \left[\frac{V \times 0.120 \text{ m}}{22.10 \times 10^{-6} \text{ m}^2/\text{s}} \right]^{0.85} (0.706)^{1/3}$$

From which we may find $V = 13.2 \text{ m/s}$ <

COMMENTS: (1) In Part (a), the chip surface temperature increased from 42.4°C to 47.2°C . This is considered to be significant and the electronics packaging engineer needs to consider the effect of large changes in atmospheric pressure on the efficacy of the electronics cooling scheme. (2) Careful consideration needs to be given to the effect changes in the atmospheric pressure on the kinematic viscosity and, in turn, on changes in transition lengths which might dramatically affect local convective heat transfer coefficients.

PROBLEM 6.28

KNOWN: Location and dimensions of computer chip on a circuit board. Form of the convection correlation. Maximum allowable chip temperature and surface emissivity. Temperature of cooling air and surroundings.

FIND: Effect of air velocity on maximum power dissipation, first without and then with consideration of radiation effects.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible temperature variations in chip, (3) Heat transfer exclusively from the top surface of the chip, (4) The local heat transfer coefficient at $x = L$ provides a good approximation to the average heat transfer coefficient for the chip surface.

PROPERTIES: Table A.4, air ($\bar{T} = (T_\infty + T_c)/2 = 328 \text{ K}$): $\nu = 18.71 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0284 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.703$.

ANALYSIS: Performing an energy balance for a control surface about the chip, we obtain $P_c = q_{\text{conv}} + q_{\text{rad}}$, where $q_{\text{conv}} = \bar{h}A_s(T_c - T_\infty)$, $q_{\text{rad}} = h_r A_s(T_c - T_{\text{sur}})$, and $h_r = \varepsilon \sigma (T_c + T_{\text{sur}})(T_c^2 + T_{\text{sur}}^2)$. With $\bar{h} \approx h_L$, the convection coefficient may be determined from the correlation provided in Problem 6.26 ($\text{Nu}_L = 0.04 \text{Re}_L^{0.85} \text{Pr}^{1/3}$). Hence,

$$P_c = \ell^2 \left[0.04(k/L) \text{Re}_L^{0.85} \text{Pr}^{1/3} (T_c - T_\infty) + \varepsilon \sigma (T_c + T_{\text{sur}})(T_c^2 + T_{\text{sur}}^2)(T_c - T_{\text{sur}}) \right]$$

where $\text{Re}_L = VL/\nu$. Computing the right side of this expression for $\varepsilon = 0$ and $\varepsilon = 0.85$, we obtain the following results.

Since h_L increases as $V^{0.85}$, the chip power must increase with V in the same manner. Radiation exchange increases P_c by a fixed, but small (6 mW) amount. While h_L varies from 14.5 to 223 $\text{W/m}^2\cdot\text{K}$ over the prescribed velocity range, $h_r = 6.5 \text{ W/m}^2\cdot\text{K}$ is a constant, independent of V .

COMMENTS: Alternatively, \bar{h} could have been evaluated by integrating h_x over the range $118 \leq x \leq 122 \text{ mm}$ to obtain the appropriate average. However, the value would be extremely close to $h_{x=L}$.

PROBLEM 6.29

KNOWN: Form of Nusselt number for flow of air or a dielectric liquid over components of a circuit card.

FIND: Ratios of time constants associated with intermittent heating and cooling. Fluid that provides faster thermal response.

PROPERTIES: Prescribed. Air: $k = 0.026 \text{ W/m}\cdot\text{K}$, $\nu = 2 \times 10^{-5} \text{ m}^2/\text{s}$, $\text{Pr} = 0.71$. Dielectric liquid: $k = 0.064 \text{ W/m}\cdot\text{K}$, $\nu = 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 25$.

ANALYSIS: From Eq. 5.7, the thermal time constant is

$$\tau_t = \frac{\rho \forall c}{h A_s}$$

Since the only variable that changes with the fluid is the convection coefficient, where

$$\bar{h} = \frac{k}{L} \overline{\text{Nu}}_L = \frac{k}{L} C \text{Re}_L^m \text{Pr}^n = \frac{k}{L} C \left(\frac{VL}{\nu} \right)^m \text{Pr}^n$$

the desired ratio reduces to

$$\frac{\tau_{t,\text{air(a)}}}{\tau_{t,\text{dielectric(d)}}} = \frac{\bar{h}_d}{\bar{h}_a} = \frac{k_d}{k_a} \left(\frac{\nu_a}{\nu_d} \right)^m \left(\frac{\text{Pr}_d}{\text{Pr}_a} \right)^n$$
$$\frac{\tau_{t,a}}{\tau_{t,d}} = \frac{0.064}{0.026} \left(\frac{2 \times 10^{-5}}{10^{-6}} \right)^{0.8} \left(\frac{25}{0.71} \right)^{0.33} = 88.6$$

Since its time constant is nearly two orders of magnitude smaller than that of the air, the dielectric liquid is clearly the fluid of choice. <

COMMENTS: The accelerated testing procedure suggested by this problem is commonly used to test the durability of electronic packages.

PROBLEM 6.30

KNOWN: Form of the Nusselt number correlation for forced convection and fluid properties.

FIND: Expression for figure of merit F_F and values for air, water and a dielectric liquid.

PROPERTIES: Prescribed. Air: $k = 0.026 \text{ W/m}\cdot\text{K}$, $\nu = 1.6 \times 10^{-5} \text{ m}^2/\text{s}$, $\text{Pr} = 0.71$. Water: $k = 0.600 \text{ W/m}\cdot\text{K}$, $\nu = 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 5.0$. Dielectric liquid: $k = 0.064 \text{ W/m}\cdot\text{K}$, $\nu = 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 25$

ANALYSIS: With $\text{Nu}_L \sim \text{Re}_L^m \text{Pr}^n$, the convection coefficient may be expressed as

$$h \sim \frac{k}{L} \left(\frac{VL}{\nu} \right)^m \text{Pr}^n \sim \frac{V^m}{L^{1-m}} \left(\frac{k \text{Pr}^n}{\nu^m} \right)$$

The figure of merit is therefore

$$F_F = \frac{k \text{Pr}^n}{\nu^m} \quad <$$

and for the three fluids, with $m = 0.80$ and $n = 0.33$,

$$F_F \left(\text{W} \cdot \text{s}^{0.8} / \text{m}^{2.6} \cdot \text{K} \right) \quad \begin{array}{c} \text{Air} \\ 167 \end{array} \quad \begin{array}{c} \text{Water} \\ 64,400 \end{array} \quad \begin{array}{c} \text{Dielectric} \\ 11,700 \end{array} \quad <$$

Water is clearly the superior heat transfer fluid, while air is the least effective.

COMMENTS: The figure of merit indicates that heat transfer is enhanced by fluids of large k , large Pr and small ν .

PROBLEM 6.31

KNOWN: Form of the Nusselt number correlation for forced convection and fluid properties. Properties of xenon and He-Xe mixture. Temperature and pressure. Expression for specific heat for monatomic gases.

FIND: Figures of merit for air, pure helium, pure xenon, and He-Xe mixture containing 0.75 mole fraction of helium.

PROPERTIES: Table A-4, Air (300 K): $k = 0.0263 \text{ W/m}\cdot\text{K}$, $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 0.707$. Table A-4, Helium (300 K): $k = 0.152 \text{ W/m}\cdot\text{K}$, $\nu = 122 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 0.680$. Pure xenon (given): $k = 0.006 \text{ W/m}\cdot\text{K}$, $\mu = 24.14 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$. He-Xe mixture (given): $k = 0.0713 \text{ W/m}\cdot\text{K}$, $\mu = 25.95 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$.

ANALYSIS: With $\text{Nu}_L \sim \text{Re}_L^m \text{Pr}^n$, the convection coefficient may be expressed as

$$h \sim \frac{k}{L} \left(\frac{VL}{\nu} \right)^m \text{Pr}^n \sim \frac{V^m}{L^{1-m}} \left(\frac{k \text{Pr}^n}{\nu^m} \right)$$

The figure of merit is therefore

$$F_F = \frac{k \text{Pr}^n}{\nu^m} \quad (1)$$

For xenon and the He-Xe mixture, we must find the density and specific heat. Proceeding for pure xenon:

$$\rho = \frac{P\mathcal{M}}{\mathcal{R}T} = \frac{1 \text{ atm} \times 131.29 \text{ kg/kmol}}{8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm} / \text{kmol} \cdot \text{K} \times 300 \text{ K}} = 5.33 \text{ kg/m}^3$$

$$c_p = \frac{5}{2} \frac{\mathcal{R}}{\mathcal{M}} = \frac{5}{2} \frac{8.315 \times 10^3 \text{ J/kmol} \cdot \text{K}}{131.29 \text{ kg/kmol}} = 158 \text{ J/kg}$$

Thus $\nu = \mu/\rho = 24.14 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 / 5.33 \text{ kg/m}^3 = 4.53 \times 10^{-6} \text{ m}^2/\text{s}$ and $\text{Pr} = \mu c_p / k = 24.14 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 158 \text{ J/kg} / 0.006 \text{ W/m}\cdot\text{K} = 0.636$.

For the He-Xe mixture, the molecular weight of the mixture can be found from

$$\mathcal{M}_{\text{mix}} = 0.75 \text{ kmol He/kmol} \times 4.0 \text{ kg/kmol He} + 0.25 \text{ kmol Xe/kmol} \times 131.29 \text{ kg/kmol Xe} = 35.82 \text{ kg/kmol}$$

from which we can calculate $\rho = 1.46 \text{ kg/m}^3$, $c_p = 580 \text{ J/kg}\cdot\text{K}$, $\nu = \mu/\rho = 25.95 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 / 1.46 \text{ kg/m}^3 = 1.78 \times 10^{-5} \text{ m}^2/\text{s}$, and $\text{Pr} = \mu c_p / k = 25.95 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times 580 \text{ J/kg} / 0.0713 \text{ W/m}\cdot\text{K} = 0.211$.

Finally, for the four fluids, with $m = 0.85$ and $n = 0.33$, we can calculate the figure of merit from Equation (1):

	$F_F (\text{W}\cdot\text{s}^{0.85}/\text{m}^{2.7}\cdot\text{K})$	<
Air	281	
Helium	284	
Xenon	180	
He-Xe	465	

COMMENTS: The effectiveness of the He-Xe mixture is much higher than that of pure He, pure Xe, or air. By blending He and Xe, the high thermal conductivity of helium and the high density of xenon are both exploited in a manner that leads to a high figure of merit.

PROBLEM 6.32

KNOWN: Ambient, interior and dewpoint temperatures. Vehicle speed and dimensions of windshield. Heat transfer correlation for external flow.

FIND: Minimum value of convection coefficient needed to prevent condensation on interior surface of windshield.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional heat transfer, (3) Constant properties.

PROPERTIES: Table A-3, glass: $k_g = 1.4 \text{ W/m}\cdot\text{K}$. Prescribed, air: $k = 0.023 \text{ W/m}\cdot\text{K}$, $\nu = 12.5 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 0.70$.

ANALYSIS: From the prescribed thermal circuit, conservation of energy yields

$$\frac{T_{\infty,i} - T_{s,i}}{1/\bar{h}_i} = \frac{T_{s,i} - T_{\infty,o}}{t/k_g + 1/\bar{h}_o}$$

where \bar{h}_o may be obtained from the correlation

$$\text{Nu}_L = \frac{\bar{h}_o L}{k} = 0.030 \text{Re}_L^{0.8} \text{Pr}^{1/3}$$

With $V = (70 \text{ mph} \times 1585 \text{ m/mile})/3600 \text{ s/h} = 30.8 \text{ m/s}$, $\text{Re}_D = (30.8 \text{ m/s} \times 0.800 \text{ m})/12.5 \times 10^{-6} \text{ m}^2/\text{s} = 1.97 \times 10^6$ and

$$\bar{h}_o = \frac{0.023 \text{ W/m}\cdot\text{K}}{0.800 \text{ m}} 0.030 (1.97 \times 10^6)^{0.8} (0.70)^{1/3} = 83.1 \text{ W/m}^2 \cdot \text{K}$$

From the energy balance, with $T_{s,i} = T_{dp} = 10^\circ\text{C}$

$$\bar{h}_i = \frac{(T_{s,i} - T_{\infty,o})}{(T_{\infty,i} - T_{s,i})} \left(\frac{t}{k_g} + \frac{1}{\bar{h}_o} \right)^{-1}$$

$$\bar{h}_i = \frac{(10 + 15)^\circ\text{C}}{(50 - 10)^\circ\text{C}} \left(\frac{0.006 \text{ m}}{1.4 \text{ W/m}\cdot\text{K}} + \frac{1}{83.1 \text{ W/m}^2 \cdot \text{K}} \right)^{-1}$$

$$\bar{h}_i = 38.3 \text{ W/m}^2 \cdot \text{K}$$

<

COMMENTS: The output of the fan in the automobile's heater/defroster system must maintain a velocity for flow over the inner surface that is large enough to provide the foregoing value of \bar{h}_i . In addition, the output of the heater must be sufficient to maintain the prescribed value of $T_{\infty,i}$ at this velocity.

PROBLEM 6.33

KNOWN: Characteristic length of a microscale chemical detector, free stream velocity and temperature, hydrogen wind tunnel pressure and free stream velocity.

FIND: Model length scale and hydrogen temperature needed for similarity.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible microscale or nanoscale effects, (4) Ideal gas behavior.

PROPERTIES: Table A.4, air ($T = 25^\circ\text{C}$): $\text{Pr}_s = 0.707$, $\nu_s = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$, hydrogen (250 K) $\text{Pr} = 0.707$, $\nu = 81.4 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: For similarity we require $\text{Re}_m = \text{Re}_s$ and $\text{Pr}_m = \text{Pr}_s$. For the sensor,

$$\text{Re}_s = \frac{V_s L_s}{\nu_s} = \frac{10 \text{ m/s} \times 80 \times 10^{-6} \text{ m}}{1.571 \times 10^{-5} \text{ m}^2/\text{s}} = 50.93$$

$$\text{Pr}_s = 0.707$$

For the model, $\text{Pr}_m = \text{Pr}_s = 0.707$.

From Table A.4, we note $\text{Pr}_s = 0.707$, $\nu = 81.4 \times 10^{-6} \text{ m}^2/\text{s}$ at $T_\infty = 250 \text{ K}$ and $p = 1 \text{ atm}$. <

The value of the Prandtl number is independent of pressure for an ideal gas. The kinematic viscosity is pressure-dependent. Hence,

$$\nu(\text{at } 0.5 \text{ atm}) = \frac{\mu}{\rho(\text{at } 0.5 \text{ atm})} = \frac{\mu}{\rho(\text{at } 1.0 \text{ atm})} \times \frac{\rho(\text{at } 1.0 \text{ atm})}{\rho(\text{at } 0.5 \text{ atm})}$$

For an ideal gas,

$$\nu(\text{at } 0.5 \text{ atm}) = \nu(\text{at } 1.0 \text{ atm}) \times \frac{1.0 \text{ atm}}{0.5 \text{ atm}} = 2\nu(\text{at } 1.0 \text{ atm})$$

Therefore,

$$\nu_m = 81.4 \times 10^{-6} \text{ m}^2/\text{s} \times 2 = 163 \times 10^{-6} \text{ m}^2/\text{s}$$

For similarity,

Continued...

PROBLEM 6.33 (Cont.)

$$\text{Re}_m = \text{Re}_s = 50.93 = \frac{V_m L_m}{\nu_m} = \frac{0.5 \text{ m/s} \times L_m}{163 \times 10^{-6} \text{ m}^2/\text{s}}$$

or $L_m = 16.6 \times 10^{-3} \text{ m} = 16.6 \text{ mm}$

<

COMMENTS: (1) From Section 2.2.1, we know that the mean free path of air at room conditions is approximately 80 nm. Since L_s is three orders of magnitude greater than the mean free path, the air may be treated as a continuum. (2) Hydrogen can leak from enclosures easily. By keeping the wind tunnel pressure below atmospheric, we avoid possible leakage of flammable hydrogen into the lab. Also, if leaks occur, air must enter the wind tunnel. It is much easier to seal against air leaks than hydrogen leaks. (3) $\text{Pr}_m = 0.707$ at 100 K also. However, the operation of the hydrogen wind tunnel at such a low temperature would be much more difficult than at 250 K.

PROBLEM 6.34

KNOWN: Drag force and air flow conditions associated with a flat plate.

FIND: Rate of heat transfer from the plate.

SCHEMATIC:

ASSUMPTIONS: (1) Chilton-Colburn analogy is applicable.

PROPERTIES: Table A-4, Air (70°C , 1 atm): $\rho = 1.018\text{ kg/m}^3$, $c_p = 1009\text{ J/kg}\cdot\text{K}$, $\text{Pr} = 0.70$, $\nu = 20.22 \times 10^{-6}\text{ m}^2/\text{s}$.

ANALYSIS: The rate of heat transfer from the plate is

$$q = 2\bar{h}(L^2)(T_s - T_\infty)$$

where \bar{h} may be obtained from the Chilton-Colburn analogy,

$$\frac{\bar{h}}{\rho u_\infty c_p} = \frac{\bar{C}_f}{2} = \text{St} \text{Pr}^{2/3} = \frac{\bar{h}}{\rho u_\infty c_p} \text{Pr}^{2/3}$$

$$\frac{\bar{C}_f}{2} = \frac{1}{2} \frac{\bar{\tau}_s}{\rho u_\infty^2 / 2} = \frac{1}{2} \frac{(0.075\text{ N}/2)/(0.2\text{ m})^2}{1.018\text{ kg/m}^3 (40\text{ m/s})^2 / 2} = 5.76 \times 10^{-4}.$$

Hence,

$$\bar{h} = \frac{C_f}{2} \rho u_\infty c_p \text{Pr}^{-2/3}$$

$$\bar{h} = 5.76 \times 10^{-4} (1.018\text{ kg/m}^3) 40\text{ m/s} (1009\text{ J/kg}\cdot\text{K}) (0.70)^{-2/3}$$

$$\bar{h} = 30\text{ W/m}^2 \cdot \text{K}.$$

The heat rate is

$$q = 2(30\text{ W/m}^2 \cdot \text{K})(0.2\text{ m})^2 (120 - 20)^\circ\text{C}$$

$$q = 240\text{ W}.$$

<

COMMENTS: Although the flow is laminar over the entire surface ($\text{Re}_L = u_\infty L / \nu = 40\text{ m/s} \times 0.2\text{ m} / 20.22 \times 10^{-6}\text{ m}^2/\text{s} = 4.0 \times 10^5$), the pressure gradient is zero and the Chilton-Colburn analogy is applicable to *average*, as well as *local*, surface conditions. Note that the only contribution to the drag force is made by the surface shear stress.

PROBLEM 6.35

KNOWN: Air flow conditions and drag force associated with a heater of prescribed surface temperature and area.

FIND: Required heater power.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Reynolds analogy is applicable, (3) Bottom surface is adiabatic.

PROPERTIES: Table A-4, Air ($T_f = 350\text{K}$, 1 atm): $\rho = 0.995\text{ kg/m}^3$, $c_p = 1009\text{ J/kg}\cdot\text{K}$, $\text{Pr} = 0.700$.

ANALYSIS: The average shear stress and friction coefficient are

$$\bar{\tau}_s = \frac{F_D}{A} = \frac{0.25\text{ N}}{0.25\text{ m}^2} = 1\text{ N/m}^2$$

$$\bar{C}_f = \frac{\bar{\tau}_s}{\rho u_\infty^2 / 2} = \frac{1\text{ N/m}^2}{0.995\text{ kg/m}^3 (15\text{ m/s})^2 / 2} = 8.93 \times 10^{-3}.$$

From the Reynolds analogy,

$$\bar{St} = \frac{\bar{h}}{\rho u_\infty c_p} = \frac{\bar{C}_f}{2} \text{Pr}^{-2/3}.$$

Solving for \bar{h} and substituting numerical values, find

$$\bar{h} = 0.995\text{ kg/m}^3 (15\text{ m/s}) 1009\text{ J/kg}\cdot\text{K} \left(8.93 \times 10^{-3} / 2 \right) (0.7)^{-2/3}$$

$$\bar{h} = 85\text{ W/m}^2 \cdot \text{K}.$$

Hence, the heat rate is

$$q = \bar{h} A (T_s - T_\infty) = 85\text{ W/m}^2 \cdot \text{K} \left(0.25\text{ m}^2 \right) (140 - 15)^\circ\text{C}$$

$$q = 2.66\text{ kW}.$$

<

COMMENTS: Due to bottom heat losses, which have been assumed negligible, the actual power requirement would exceed 2.66 kW.

PROBLEM 6.36

KNOWN: Heat transfer correlation associated with parallel flow over a rough flat plate. Velocity and temperature of air flow over the plate.

FIND: Surface shear stress 1 m from the leading edge.

SCHEMATIC:

ASSUMPTIONS: (1) Modified Reynolds analogy is applicable, (2) Constant properties.

PROPERTIES: Table A-4, Air (300K, 1atm): $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 0.71$, $\rho = 1.16 \text{ kg/m}^3$.

ANALYSIS: Applying the Chilton-Colburn analogy

$$\frac{C_f}{2} = \text{St}_x \text{Pr}^{2/3} = \frac{\text{Nu}_x}{\text{Re}_x \text{Pr}} \text{Pr}^{2/3} = \frac{0.04 \text{Re}_x^{0.9} \text{Pr}^{1/3}}{\text{Re}_x \text{Pr}} \text{Pr}^{2/3}$$

$$\frac{C_f}{2} = 0.04 \text{Re}_x^{-0.1}$$

where

$$\text{Re}_x = \frac{u_\infty x}{\nu} = \frac{50 \text{ m/s} \times 1 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 3.15 \times 10^6.$$

Hence, the friction coefficient is

$$C_f = 0.08 \left(3.15 \times 10^6 \right)^{-0.1} = 0.0179 = \tau_s / \left(\rho u_\infty^2 / 2 \right)$$

and the surface shear stress is

$$\tau_s = C_f \left(\rho u_\infty^2 / 2 \right) = 0.0179 \times 1.16 \text{ kg/m}^3 (50 \text{ m/s})^2 / 2$$

$$\tau_s = 25.96 \text{ kg/m} \cdot \text{s}^2 = 25.96 \text{ N/m}^2.$$

<

COMMENTS: Note that turbulent flow will exist at the designated location.

PROBLEM 6.37

KNOWN: Dimensions and temperature of a thin, rough plate. Velocity of air flow parallel to plate (at an angle of 45° to a side). Heat transfer rate from plate to air.

FIND: Drag force on plate.

SCHEMATIC:

ASSUMPTIONS: (1) The modified Reynolds analogy holds, (2) Constant properties.

PROPERTIES: Table A-4, Air (50°C = 323 K): $c_p = 1008 \text{ J/kg}\cdot\text{K}$, $\text{Pr} = 0.704$.

ANALYSIS: The modified Reynolds analogy, Equation 6.70, combined with the definition of the Stanton number, Equation 6.67, yields

$$C_f/2 = (\text{Nu}/\text{Re})\text{Pr}^{-1/3} \quad (1)$$

The drag force is related to the friction coefficient according to

$$F_D = \tau_s A_s = C_f \cdot \rho u_\infty^2 A_s / 2 \quad (2)$$

Combining Equations (1) and (2)

$$F_D = \frac{\text{Nu}}{\text{Re}} \text{Pr}^{-1/3} \rho u_\infty^2 A_s$$

Substituting the definitions of Nu and Re, we find

$$F_D = \frac{h L_c}{k} \frac{v}{u_\infty L_c} \text{Pr}^{-1/3} \rho u_\infty^2 A_s = \frac{h}{c_p} \frac{v}{\alpha} \text{Pr}^{-1/3} u_\infty A_s = \frac{h}{c_p} \text{Pr}^{2/3} u_\infty A_s$$

Where L_c is a characteristic length used to define Nu and Re. With $h A_s = q / \Delta T$ we have

$$F_D = \frac{q u_\infty \text{Pr}^{2/3}}{c_p \Delta T} = \frac{2000 \text{ W} \times 30 \text{ m/s} \times (0.704)^{2/3}}{1008 \text{ J/kg} \cdot \text{K} \times 60 \text{ K}} = 0.785 \text{ N} \quad <$$

COMMENTS: (1) Heat transfer or friction coefficient correlations for this simple configuration apparently do not exist. (2) Experiments to measure the drag force would be relatively simple to implement and measured drag forces could be used to determine the heat transfer coefficients using the Reynolds analogy. (3) The solution demonstrates advantages associated with working the problem symbolically and only introducing numbers at the end. First, the length scale in Nu and Re did not have to be defined because it cancelled out. Second, the properties k , v , and ρ also cancelled out.

PROBLEM 6.38

KNOWN: Nominal operating conditions of aircraft and characteristic length and average friction coefficient of wing.

FIND: Average heat flux needed to maintain prescribed surface temperature of wing.

SCHEMATIC:

ASSUMPTIONS: (1) Applicability of modified Reynolds analogy, (2) Constant properties.

PROPERTIES: Prescribed, Air: $\nu = 16.3 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.022 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.72$.

ANALYSIS: The average heat flux that must be maintained over the surface of the air foil is $\bar{q}'' = \bar{h}(T_s - T_\infty)$, where the average convection coefficient may be obtained from the modified Reynolds analogy.

$$\frac{\bar{C}_f}{2} = \text{St} \text{Pr}^{2/3} = \frac{\bar{\text{Nu}}_L}{\text{Re}_L \text{Pr}} \text{Pr}^{2/3} = \frac{\bar{\text{Nu}}_L}{\text{Re}_L \text{Pr}^{1/3}}$$

Hence, with $\text{Re}_L = VL/\nu = 100 \text{ m/s}(2\text{ m})/16.3 \times 10^{-6} \text{ m}^2/\text{s} = 1.23 \times 10^7$,

$$\bar{\text{Nu}}_L = \frac{0.0025}{2} (1.23 \times 10^7) (0.72)^{1/3} = 13,780$$

$$\bar{h} = \frac{k}{L} \bar{\text{Nu}}_L = \frac{0.022 \text{ W/m}\cdot\text{K}}{2\text{ m}} (13,780) = 152 \text{ W/m}^2 \cdot \text{K}$$

$$\bar{q}'' = 152 \text{ W/m}^2 \cdot \text{K} [5 - (-23)]^\circ\text{C} = 4260 \text{ W/m}^2 \quad <$$

COMMENTS: If the flow is turbulent over the entire airfoil, the modified Reynolds analogy provides a good measure of the relationship between surface friction and heat transfer. The relation becomes more approximate with increasing laminar boundary layer development on the surface and increasing values of the magnitude of the pressure gradient.

PROBLEM 6.39

KNOWN: Average frictional shear stress of $\bar{\tau}_s = 0.0625 \text{ N/m}^2$ on upper surface of circuit board with densely packed integrated circuits (ICs)

FIND: Allowable power dissipation from the upper surface of the board if the average surface temperature of the ICs must not exceed a rise of 25°C above ambient air temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) The modified Reynolds analogy is applicable, (3) Negligible heat transfer from bottom side of the circuit board, and (4) Thermophysical properties required for the analysis evaluated at 300 K ,

PROPERTIES: Table A-4, Air ($T_f = 300 \text{ K}$, 1 atm): $\rho = 1.161 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg}\cdot\text{K}$, $\text{Pr} = 0.707$.

ANALYSIS: The power dissipation from the circuit board can be calculated from the convection rate equation assuming an excess temperature $(T_s - T_\infty) = 25^\circ\text{C}$.

$$q = \bar{h} A_s (T_s - T_\infty) \quad (1)$$

The average convection coefficient can be estimated from the Reynolds analogy and the measured average frictional shear stress $\bar{\tau}_s$.

$$\frac{\bar{C}_f}{2} = \bar{\text{St}} \text{Pr}^{2/3} \quad \bar{C}_f = \frac{\bar{\tau}_s}{\rho V^2 / 2} \quad \bar{\text{St}} = \frac{\bar{h}}{\rho V c_p} \quad (2,3,4)$$

With $V = u_\infty$ and substituting numerical values, find \bar{h} .

$$\frac{\bar{\tau}_s}{\rho V^2} = \frac{\bar{h}}{\rho V c_p} \text{Pr}^{2/3}$$

$$\bar{h} = \frac{\bar{\tau}_s c_p}{V} \text{Pr}^{-2/3}$$

$$\bar{h} = \frac{0.0625 \text{ N/m}^2 \times 1007 \text{ J/kg}\cdot\text{K}}{2 \text{ m/s}} (0.707)^{-2/3} = 39.7 \text{ W/m}^2 \cdot \text{K}$$

Substituting this result into Eq. (1), the allowable power dissipation is

$$q = 39.7 \text{ W/m}^2 \cdot \text{K} \times (0.120 \times 0.120) \text{ m}^2 \times 25 \text{ K} = 14.3 \text{ W} \quad <$$

COMMENTS: For this analysis using the modified or Chilton-Colburn analogy, we found $C_f = 0.0269$ and $\text{St} = 0.0170$. Using the Reynolds analogy, the results are slightly different with

$$\bar{h} = 31.5 \text{ W/m}^2 \cdot \text{K} \quad \text{and} \quad q = 11.3 \text{ W}.$$

PROBLEM 6.40

KNOWN: Evaporation rate of water from a lake.

FIND: The convection mass transfer coefficient, \bar{h}_m .

SCHEMATIC:

ASSUMPTIONS: (1) Equilibrium at water vapor-liquid surface, (2) Isothermal conditions, (3) Perfect gas behavior of water vapor, (4) Air at standard atmospheric pressure.

PROPERTIES: Table A-6, Saturated water vapor (300K): $p_{A,\text{sat}} = 0.03531 \text{ bar}$, $\rho_{A,\text{sat}} = 1/v_g = 0.02556 \text{ kg/m}^3$.

ANALYSIS: The convection mass transfer (evaporation) rate equation can be written in the form

$$\bar{h}_m = \frac{n''_A}{(\rho_{A,s} - \rho_{A,\infty})}$$

where

$$\rho_{A,s} = \rho_{A,\text{sat}}$$

the saturation density at the temperature of the water and

$$\rho_{A,\infty} = \phi \rho_{A,\text{sat}}$$

which follows from the definition of the relative humidity, $\phi = p_A/p_{A,\text{sat}}$ and perfect gas behavior. Hence,

$$\bar{h}_m = \frac{n''_A}{\rho_{A,\text{sat}}(1 - \phi)}$$

and substituting numerical values, find

$$\bar{h}_m = \frac{0.1 \text{ kg/m}^2 \cdot \text{h} \times 1/3600 \text{ s/h}}{0.02556 \text{ kg/m}^3 (1 - 0.3)} = 1.55 \times 10^{-3} \text{ m/s.}$$

<

COMMENTS: (1) From knowledge of $p_{A,\text{sat}}$, the perfect gas law could be used to obtain the saturation density.

$$\rho_{A,\text{sat}} = \frac{p_{A,\text{sat}} \mathcal{M}_A}{\mathcal{R}T} = \frac{0.03531 \text{ bar} \times 18 \text{ kg/kmol}}{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} (300\text{K})} = 0.02548 \text{ kg/m}^3.$$

This value is within 0.3% of that obtained from Table A-6.

(2) Note that psychrometric charts could also be used to obtain $\rho_{A,\text{sat}}$ and $\rho_{A,\infty}$.

PROBLEM 6.41

KNOWN: Evaporation rate from pan of water of prescribed diameter. Water temperature. Air temperature and relative humidity.

FIND: (a) Convection mass transfer coefficient, (b) Evaporation rate for increased relative humidity, (c) Evaporation rate for increased temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Water vapor is saturated at liquid interface and may be approximated as a perfect gas.

PROPERTIES: Table A-6, Saturated water vapor ($T_s = 296\text{K}$): $\rho_{A,\text{sat}} = v_g^{-1} = (49.4 \text{ m}^3/\text{kg})^{-1} = 0.0202 \text{ kg/m}^3$; ($T_s = 320 \text{ K}$): $\rho_{A,\text{sat}} = v_g^{-1} = (13.98 \text{ m}^3/\text{kg})^{-1} = 0.0715 \text{ kg/m}^3$.

ANALYSIS: (a) Since evaporation is a convection mass transfer process, the rate equation has the form $\dot{m}_{\text{evap}} = \bar{h}_m A (\rho_{A,s} - \rho_{A,\infty})$ and the mass transfer coefficient is

$$\bar{h}_m = \frac{\dot{m}_{\text{evap}}}{(\pi D^2/4)(\rho_{A,s} - \rho_{A,\infty})} = \frac{1.5 \times 10^{-5} \text{ kg/s}}{(\pi/4)(0.23 \text{ m})^2 0.0202 \text{ kg/m}^3} = 0.0179 \text{ m/s} <$$

with $T_s = T_\infty = 23^\circ\text{C}$ and $\phi_\infty = 0$.

(b) If the relative humidity of the ambient air is increased to 50%, the ratio of the evaporation rates is

$$\frac{\dot{m}_{\text{evap}}(\phi_\infty = 0.5)}{\dot{m}_{\text{evap}}(\phi_\infty = 0)} = \frac{\bar{h}_m A [\rho_{A,s}(T_s) - \phi_\infty \rho_{A,s}(T_\infty)]}{\bar{h}_m A \rho_{A,s}(T_s)} = 1 - \phi_\infty \frac{\rho_{A,s}(T_\infty)}{\rho_{A,s}(T_s)}.$$

$$\text{Hence, } \dot{m}_{\text{evap}}(\phi_\infty = 0.5) = 1.5 \times 10^{-5} \text{ kg/s} \left[1 - 0.5 \frac{0.0202 \text{ kg/m}^3}{0.0202 \text{ kg/m}^3} \right] = 0.75 \times 10^{-5} \text{ kg/s}.$$

(c) If the temperature of the ambient air is increased from 23°C to 47°C , with $\phi_\infty = 0$ for both cases, the ratio of the evaporation rates is

$$\frac{\dot{m}_{\text{evap}}(T_s = T_\infty = 47^\circ\text{C})}{\dot{m}_{\text{evap}}(T_s = T_\infty = 23^\circ\text{C})} = \frac{\bar{h}_m A \rho_{A,s}(47^\circ\text{C})}{\bar{h}_m A \rho_{A,s}(23^\circ\text{C})} = \frac{\rho_{A,s}(47^\circ\text{C})}{\rho_{A,s}(23^\circ\text{C})}.$$

$$\text{Hence, } \dot{m}_{\text{evap}}(T_s = T_\infty = 47^\circ\text{C}) = 1.5 \times 10^{-5} \text{ kg/s} \frac{0.0715 \text{ kg/m}^3}{0.0202 \text{ kg/m}^3} = 5.31 \times 10^{-5} \text{ kg/s}. <$$

COMMENTS: Note the highly nonlinear dependence of the evaporation rate on the water temperature. For a 24°C rise in T_s , \dot{m}_{evap} increases by 350%.

PROBLEM 6.42

KNOWN: Water temperature and air temperature and relative humidity. Surface recession rate.

FIND: Mass evaporation rate per unit area. Convection mass transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Water vapor may be approximated as a perfect gas, (2) No water inflow; outflow is only due to evaporation.

PROPERTIES: Table A-6, Saturated water: Vapor (305K), $\rho_g = v_g^{-1} = 0.0336 \text{ kg/m}^3$; Liquid (305K), $\rho_f = v_f^{-1} = 995 \text{ kg/m}^3$.

ANALYSIS: Applying conservation of species to a control volume about the water,

$$\begin{aligned} -\dot{M}_{A,\text{out}} &= \dot{M}_{A,\text{st}} \\ -\dot{m}_{\text{evap}}'' A &= \frac{d}{dt}(\rho_f V) = \frac{d}{dt}(\rho_f A H) = \rho_f A \frac{dH}{dt}. \end{aligned}$$

Substituting numerical values, find

$$\dot{m}_{\text{evap}}'' = -\rho_f \frac{dH}{dt} = -995 \text{ kg/m}^3 \left(-10^{-4} \text{ m/h} \right) \left(1/3600 \text{ s/h} \right)$$

$$\dot{m}_{\text{evap}}'' = 2.76 \times 10^{-5} \text{ kg/s} \cdot \text{m}^2.$$

Because evaporation is a convection mass transfer process, it also follows that

$$\dot{m}_{\text{evap}}'' = n_A''$$

or in terms of the rate equation,

$$\begin{aligned} \dot{m}_{\text{evap}}'' &= h_m (\rho_{A,s} - \rho_{A,\infty}) = h_m [\rho_{A,\text{sat}}(T_s) - \phi_{\infty} \rho_{A,\text{sat}}(T_{\infty})] \\ \dot{m}_{\text{evap}}'' &= h_m \rho_{A,\text{sat}}(305\text{K}) (1 - \phi_{\infty}), \end{aligned}$$

and solving for the convection mass transfer coefficient,

$$h_m = \frac{\dot{m}_{\text{evap}}''}{\rho_{A,\text{sat}}(305\text{K}) (1 - \phi_{\infty})} = \frac{2.76 \times 10^{-5} \text{ kg/s} \cdot \text{m}^2}{0.0336 \text{ kg/m}^3 (1 - 0.4)}$$

$$h_m = 1.37 \times 10^{-3} \text{ m/s}.$$

COMMENTS: Conservation of species has been applied in exactly the same way as a conservation of energy. Note the sign convention.

PROBLEM 6.43

KNOWN: CO₂ concentration in air and at the surface of a green leaf. Convection mass transfer coefficient.

FIND: Rate of photosynthesis per unit area of leaf.

SCHEMATIC:

ANALYSIS: Assuming that the CO₂ (species A) is consumed as a reactant in photosynthesis at the same rate that it is transferred across the atmospheric boundary layer, the rate of photosynthesis per unit leaf surface area is given by the rate equation,

$$n''_A = h_m (\rho_{A, \infty} - \rho_{A, s}).$$

Substituting numerical values, find

$$n''_A = 10^{-2} \text{ m/s} (6 \times 10^{-4} - 5 \times 10^{-4}) \text{ kg/m}^3$$

$$n''_A = 10^{-6} \text{ kg/s} \cdot \text{m}^2.$$

<

COMMENTS: (1) It is recognized that CO₂ transport is from the air to the leaf, and $(\rho_{A, s} - \rho_{A, \infty})$ in the rate equation has been replaced by $(\rho_{A, \infty} - \rho_{A, s})$.

(2) The atmospheric concentration of CO₂ is known to be increasing by approximately 0.3% per year. This increase in $\rho_{A, \infty}$ will have the effect of increasing the photosynthesis rate and hence plant biomass production.

PROBLEM 6.44

KNOWN: Species concentration profile, $C_A(y)$, in a boundary layer at a particular location for flow over a surface.

FIND: Expression for the mass transfer coefficient, h_m , in terms of the profile constants, $C_{A,\infty}$ and D_{AB} . Expression for the molar convection flux, N_A'' .

SCHEMATIC:

ASSUMPTIONS: (1) Parameters D , E , and F are constants at any location x , (2) D_{AB} , the mass diffusion coefficient of A through B , is known.

ANALYSIS: The convection mass transfer coefficient is defined in terms of the concentration gradient at the wall,

$$h_m(x) = -D_{AB} \frac{\partial C_A / \partial y|_{y=0}}{(C_{A,s} - C_{A,\infty})}.$$

The gradient at the surface follows from the profile, $C_A(y)$,

$$\left. \frac{\partial C_A}{\partial y} \right|_{y=0} = \left. \frac{\partial}{\partial y} (Dy^2 + Ey + F) \right|_{y=0} = +E.$$

Hence,

$$h_m(x) = -\frac{D_{AB}E}{(C_{A,s} - C_{A,\infty})} = \frac{-D_{AB}E}{(F - C_{A,\infty})}. \quad <$$

The molar flux follows from the rate equation,

$$N_A'' = h_m(C_{A,s} - C_{A,\infty}) = \frac{-D_{AB}E}{(C_{A,s} - C_{A,\infty})} \cdot (C_{A,s} - C_{A,\infty}).$$

$$N_A'' = -D_{AB}E. \quad <$$

COMMENTS: It is important to recognize that the influence of species B is present in the property D_{AB} . Otherwise, all the parameters relate to species A .

PROBLEM 6.45

KNOWN: Cross flow of gas X over object with prescribed characteristic length L, Reynolds number, and average heat transfer coefficient. Thermophysical properties of gas X, liquid Y, and vapor Y.

FIND: Average mass transfer coefficient for same object when impregnated with liquid Y and subjected to same flow conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Vapor Y behaves as perfect gas

PROPERTIES:	(Given)	$\nu (\text{m}^2/\text{s})$	$k (\text{W/m} \cdot \text{K})$	$\alpha (\text{m}^2/\text{s})$
Gas X		21×10^{-6}	0.030	29×10^{-6}
Liquid Y		3.75×10^{-7}	0.665	1.65×10^{-7}
Vapor Y		4.25×10^{-5}	0.023	4.55×10^{-5}
Mixture of gas X - vapor Y: $Sc = 0.72$				

ANALYSIS: The heat-mass transfer analogy may be written as

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = f(Re_L, Pr) \quad \overline{Sh}_L = \frac{\bar{h}_{m,L} L}{D_{AB}} = f(Re_L, Sc)$$

The flow conditions are the same for both situations. Check values of Pr and Sc. For Pr, the properties are those for gas X (B).

$$Pr = \frac{\nu_B}{\alpha_B} = \frac{21 \times 10^{-6} \text{ m}^2/\text{s}}{29 \times 10^{-6} \text{ m}^2/\text{s}} = 0.72$$

while $Sc = 0.72$ for the gas X (B) - vapor Y (A) mixture. It follows for this situation

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = \overline{Sh}_L = \frac{\bar{h}_{m,L} L}{D_{AB}} \quad \text{or} \quad \bar{h}_{m,L} = \bar{h}_L \frac{D_{AB}}{k}$$

Recognizing that

$$D_{AB} = \nu_B / Sc = 21.6 \times 10^{-6} \text{ m}^2/\text{s} / (0.72) = 30.0 \times 10^{-6} \text{ m}^2/\text{s}$$

and substituting numerical values, find

$$\bar{h}_{m,L} = 25 \text{ W/m}^2 \cdot \text{K} \times \frac{30.0 \times 10^{-6} \text{ m}^2/\text{s}}{0.030 \text{ W/m} \cdot \text{K}} = 0.0250 \text{ m/s.} \quad <$$

COMMENTS: Note that none of the thermophysical properties of liquid or vapor Y are required for the solution. Only the gas X properties and the Schmidt number (gas X - vapor Y) are required.

PROBLEM 6.46

KNOWN: Free stream velocity and average convection mass transfer coefficient for fluid flow over a surface of prescribed characteristic length.

FIND: Values of \overline{Sh}_L , Re_L , Sc and \overline{j}_m for (a) air flow over water, (b) air flow over naphthalene, and (c) warm glycerol over ice.

SCHEMATIC:

PROPERTIES: For the fluids at 300K:

Table	Fluid(s)	$\nu(m^2/s) \times 10^{-6}$	$D_{AB}(m^2/s)$
A-4	Air	15.89	-
A-5	Glycerin	634	-
A-8	Water vapor - Air	-	0.26×10^{-4}
A-8	Naphthalene - Air	-	0.62×10^{-5}
A-8	Water - Glycerol	-	0.94×10^{-9}

ANALYSIS: (a) *Water (vapor) - Air:*

$$\overline{Sh}_L = \frac{\overline{h}_m L}{D_{AB}} = \frac{(0.01 \text{ m/s}) 1 \text{ m}}{0.26 \times 10^{-4} \text{ m}^2/\text{s}} = 385$$

$$Re_L = \frac{VL}{\nu} = \frac{(1 \text{ m/s}) 1 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 6.29 \times 10^4$$

$$Sc = \frac{\nu}{D_{AB}} = \frac{0.16 \times 10^{-6} \text{ m}^2/\text{s}}{0.26 \times 10^{-6} \text{ m}^2/\text{s}} = 0.62$$

$$\overline{j}_m = St_m Sc^{2/3} = \frac{\overline{h}_m}{V} Sc^{2/3} = \frac{0.01 \text{ m/s}}{1 \text{ m/s}} (0.62)^{2/3} = 0.0073. \quad <$$

(b) *Naphthalene (vapor) - Air:*

$$\overline{Sh}_L = 1613 \quad Re_L = 6.29 \times 10^4 \quad Sc = 2.56 \quad \overline{j}_m = 0.0187. \quad <$$

(c) *Water (liquid) - Glycerol:*

$$\overline{Sh}_L = 1.06 \times 10^7 \quad Re_L = 1577 \quad Sc = 6.74 \times 10^5 \quad \overline{j}_m = 76.9. \quad <$$

COMMENTS: Note the association of ν with the freestream fluid B.

PROBLEM 6.47

KNOWN: Characteristic length, surface temperature, average heat flux and airstream conditions associated with an object of irregular shape.

FIND: Whether similar behavior exists for alternative conditions, and average convection coefficient for similar cases.

SCHEMATIC:

Case:	1	2	3	4	5
L, m	1	2	2	2	2
$V, \text{m/s}$	100	50	50	50	250
p, atm	1	1	0.2	1	0.2
T_∞, K	275	275	275	300	300
T_s, K	325	325	325	300	300

$q'', \text{W/m}^2$	12,000	-	-	-	-
$\bar{h}, \text{W/m}^2 \cdot \text{K}$	240	-	-	-	-
$D_{AB} \times 10^{-4}, \text{m}^2/\text{s}$	-	-	-	1.12	1.12

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable; that is, $f(\text{Re}_L, \text{Pr}) = f(\text{Re}_L, \text{Sc})$, see Eqs. 6.50 and 6.54.

PROPERTIES: Table A-4, Air (300K, 1 atm): $\nu_1 = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr}_1 = 0.71$, $k_1 = 0.0263 \text{ W/m} \cdot \text{K}$.

ANALYSIS: For Case 1, $h = q''/(T_s - T_\infty) = 12,000 \text{ W/m}^2/50 \text{ K} = 240 \text{ W/m}^2 \cdot \text{K}$.

$\text{Re}_{L,1} = V_1 L_1 / \nu_1 = (100 \text{ m/s} \times 1 \text{ m}) / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 6.29 \times 10^6$ and $\text{Pr}_1 = 0.71$.

Case 2: $\text{Re}_{L,2} = \frac{V_2 L_2}{\nu_2} = \frac{50 \text{ m/s} \times 2 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 6.29 \times 10^6$, $\text{Pr}_2 = 0.71$.

From Eq. 6.50 it follows that Case 2 is analogous to Case 1. Hence $\overline{\text{Nu}}_2 = \overline{\text{Nu}}_1$ and

$$\bar{h}_2 = \frac{\bar{h}_1 L_1}{k_1} \frac{k_2}{L_2} = \bar{h}_1 \frac{L_1}{L_2} = 240 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \frac{1 \text{ m}}{2 \text{ m}} = 120 \text{ W/m}^2 \cdot \text{K}. \quad <$$

Case 3: With $p = 0.2 \text{ atm}$, $\nu_3 = 79.45 \times 10^{-6} \text{ m}^2/\text{s}$ and $\text{Re}_{L,3} = \frac{V_3 L_3}{\nu_3} = \frac{50 \text{ m/s} \times 2 \text{ m}}{79.45 \times 10^{-6} \text{ m}^2/\text{s}} = 1.26 \times 10^6$, $\text{Pr}_3 = 0.71$.

Since $\text{Re}_{L,3} \neq \text{Re}_{L,1}$, Case 3 is not analogous to Case 1. <

Case 4: $\text{Re}_{L,4} = \text{Re}_{L,1}$, $\text{Sc}_4 = \frac{\nu_4}{D_{AB,4}} = \frac{15.89 \times 10^{-6} \text{ m}^2/\text{s}}{1.12 \times 10^{-4} \text{ m}^2/\text{s}} = 0.142 \neq \text{Pr}_1$.

Hence, Case 4 is not analogous to Case 1. <

Case 5: $\text{Re}_{L,5} = \frac{V_5 L_5}{\nu_5} = \frac{250 \text{ m/s} \times 2 \text{ m}}{79.45 \times 10^{-6} \text{ m}^2/\text{s}} = 6.29 \times 10^6 = \text{Re}_{L,1}$

$$\text{Sc}_5 = \frac{\nu_5}{D_{AB,5}} = \frac{79.45 \times 10^{-6} \text{ m}^2/\text{s}}{1.12 \times 10^{-4} \text{ m}^2/\text{s}} = 0.71 = \text{Pr}_1.$$

Hence, conditions are analogous to Case 1, and with $\overline{\text{Sh}}_5 = \overline{\text{Nu}}_1$,

$$h_{m,5} = h_1 \frac{L_1}{L_5} \frac{D_{AB,5}}{k_1} = 240 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times \frac{1 \text{ m}}{2 \text{ m}} \times \frac{1.12 \times 10^{-4} \text{ m}^2/\text{s}}{0.0263 \text{ W/m} \cdot \text{K}} = 0.51 \text{ m/s}. \quad <$$

COMMENTS: Note that Pr , k and Sc are independent of pressure, while ν and D_{AB} vary inversely with pressure.

PROBLEM 6.48

KNOWN: Surface temperature and heat loss from a runner's body on a cool, spring day. Surface temperature and ambient air-conditions for a warm summer day.

FIND: (a) Water loss on summer day, (b) Total heat loss on summer day.

SCHEMATIC:

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable. Hence, from Eqs. 6.50 and 6.54, $f(\text{Re}_L, \text{Pr})$ is of same form as $f(\text{Re}_L, \text{Sc})$, (2) Negligible surface evaporation for Case 1, (3) Constant properties, (4) Water vapor is saturated for Case 2 surface and may be approximated as a perfect gas.

PROPERTIES: Air (given): $\nu = 1.6 \times 10^{-5} \text{ m}^2/\text{s}$, $k = 0.026 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.70$; Water vapor - air (given): $D_{AB} = 2.3 \times 10^{-5} \text{ m}^2/\text{s}$; Table A-6, Saturated water vapor ($T_\infty = 303\text{K}$):

$$\rho_{A,\text{sat}} = \nu_g^{-1} = 0.030 \text{ kg/m}^3; (T_s = 308\text{K}): \rho_{A,\text{sat}} = \nu_g^{-1} = 0.039 \text{ kg/m}^3, h_{fg} = 2419 \text{ kJ/kg}.$$

ANALYSIS: (a) With $\text{Re}_{L,2} = \text{Re}_{L,1}$ and $\text{Sc} = \nu/D_{AB} = 1.6 \times 10^{-5} \text{ m}^2/\text{s} / 2.3 \times 10^{-5} \text{ m}^2/\text{s} = 0.70 = \text{Pr}$, it follows that $\overline{\text{Sh}}_L = \overline{\text{Nu}}_L$. Hence

$$\begin{aligned} \bar{h}_m L / D_{AB} &= \bar{h} L / k \\ \bar{h}_m &= \bar{h} \frac{D_{AB}}{k} = \frac{q_1}{A_s (T_s - T_\infty)_1} \frac{D_{AB}}{k} = \frac{500 \text{ W}}{A_s (20\text{K})} \frac{2.3 \times 10^{-5} \text{ m}^2/\text{s}}{0.026 \text{ W/m}\cdot\text{K}} = \left[\frac{0.0221}{A_s} \right] \text{ m/s}. \end{aligned}$$

Hence, from the rate equation, with A_s as the wetted surface

$$n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) = \left[\frac{0.0221}{A_s} \right] \frac{\text{m}}{\text{s}} A_s [\rho_{A,\text{sat}}(T_{s,2}) - \phi_\infty \rho_{A,\text{sat}}(T_{\infty,2})]$$

$$n_A = 0.0221 \text{ m}^3/\text{s} (0.039 - 0.6 \times 0.030) \text{ kg/m}^3 = 4.64 \times 10^{-4} \text{ kg/s}. \quad <$$

(b) The total heat loss for Case 2 is comprised of sensible and latent contributions, where

$$q_2 = q_{\text{sen}} + q_{\text{lat}} = \bar{h} A_s (T_{s,2} - T_{\infty,2}) + n_A h_{fg}.$$

Hence, with $\bar{h} A_s = q_1 / (T_{s,1} - T_{\infty,1}) = 25 \text{ W/K}$,

$$q_2 = 25 \text{ W/K} (35 - 30)^\circ\text{C} + 4.64 \times 10^{-4} \text{ kg/s} \times 2.419 \times 10^6 \text{ J/kg}$$

$$q_2 = 125 \text{ W} + 1122 \text{ W} = 1247 \text{ W}. \quad <$$

COMMENTS: Note the significance of the evaporative cooling effect.

PROBLEM 6.49

KNOWN: Heat transfer results for an irregularly shaped object.

FIND: (a) The concentration, C_A , and partial pressure, p_A , of vapor in an airstream for a drying process of an object of similar shape, (b) Average mass transfer flux, n''_A ($\text{kg/s} \cdot \text{m}^2$).

SCHEMATIC:

Case 1: Heat Transfer

Case 2: Mass Transfer

ASSUMPTIONS: (1) Heat-mass transfer analogy applies, (b) Perfect gas behavior.

PROPERTIES: Table A-4, Air (323K, 1 atm): $\nu = 18.20 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 0.703$, $k = 28.0 \times 10^{-3} \text{ W/m} \cdot \text{K}$; Plastic vapor (given): $\mathcal{M}_A = 82 \text{ kg/kmol}$, $p_{\text{sat}}(50^\circ\text{C}) = 0.0323 \text{ atm}$, $D_{AB} = 2.6 \times 10^{-5} \text{ m}^2/\text{s}$.

ANALYSIS: (a) Calculate Reynolds numbers

$$\text{Re}_1 = \frac{V_1 L_1}{\nu} = \frac{120 \text{ m/s} \times 1 \text{ m}}{18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 6.59 \times 10^6$$

$$\text{Re}_2 = \frac{60 \text{ m/s} \times 2 \text{ m}}{18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 6.59 \times 10^6.$$

Note that

$$\text{Pr}_1 = 0.703 \quad \text{Sc}_2 = \frac{\nu}{D_{AB}} = \frac{18.2 \times 10^{-6} \text{ m}^2/\text{s}}{2.6 \times 10^{-5} \text{ m}^2/\text{s}} = 0.700.$$

Since $\text{Re}_1 = \text{Re}_2$ and $\text{Pr}_1 = \text{Sc}_2$, the dimensionless solutions to the energy and species equations are identical. That is, from Eqs. 6.47 and 6.51,

$$T^*(x^*, y^*) = C_A^*(x^*, y^*)$$

$$\frac{T - T_s}{T_\infty - T_s} = \frac{C_A - C_{A,s}}{C_{A,\infty} - C_{A,s}} \quad (1)$$

where T^* and C_A^* are defined by Eqs. 6.33 and 6.34, respectively. Now, determine

$$C_{A,s} = \frac{p_{A,\text{sat}}}{\mathcal{R}T} = \left(0.0323 \text{ atm} / 8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \times (273 + 50) \text{ K} \right)$$

$$C_{A,s} = 1.219 \times 10^{-3} \text{ kmol/kg}.$$

Continued

PROBLEM 6.49 (Cont.)

Substituting numerical values in Eq. (1),

$$C_A = C_{A,s} + (C_{A,\infty} - C_{A,s}) \frac{T - T_s}{T_\infty - T_s}$$

$$C_A = 1.219 \times 10^{-3} \text{ kmol/m}^3 + (0 - 1.219 \times 10^{-3}) \text{ kmol/m}^3 \frac{(80 - 100)^\circ \text{C}}{(0 - 100)^\circ \text{C}}$$

$$C_A = 0.975 \times 10^{-3} \text{ kmol/m}^3.$$

<

The vapor pressure is then

$$p_A = C_A \mathcal{R}T = 0.0258 \text{ atm.}$$

<

(b) For case 1, $q'' = 2000 \text{ W/m}^2$. The rate equations are

$$q'' = \bar{h}(T_s - T_\infty) \quad (2)$$

$$n''_A = \bar{h}_m(C_{A,s} - C_{A,\infty})\mathcal{M}_A. \quad (3)$$

From the analogy

$$\overline{\text{Nu}}_L = \overline{\text{Sh}}_L \quad \rightarrow \quad \frac{\bar{h} L_1}{k} = \frac{\bar{h}_m L_2}{D_{AB}} \quad \text{or} \quad \frac{\bar{h}}{\bar{h}_m} = \frac{L_2}{L_1} \frac{k}{D_{AB}}. \quad (4)$$

Combining Eqs. (2) - (4),

$$n''_A = q'' \frac{\bar{h}_m}{\bar{h}} \frac{(C_{A,s} - C_{A,\infty})\mathcal{M}_A}{(T_s - T_\infty)} = q'' \frac{L_1 D_{AB}}{L_2 k} \frac{(C_{A,s} - C_{A,\infty})\mathcal{M}_A}{(T_s - T_\infty)}$$

which numerically gives

$$n''_A = 2000 \text{ W/m}^2 \frac{1 \text{ m} (2.6 \times 10^{-5} \text{ m}^2/\text{s})}{2 \text{ m} (28 \times 10^{-3} \text{ W/m} \cdot \text{K})} \frac{(1.219 \times 10^{-3} - 0) \text{ kmol/m}^3 (82 \text{ kg/kmol})}{(100 - 0) \text{ K}}$$

$$n''_A = 9.28 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2.$$

<

COMMENTS: Recognize that the analogy between heat and mass transfer applies when the conservation equations and boundary conditions are of the same form.

PROBLEM 6.50

KNOWN: Convection heat transfer correlation for flow over a contoured surface.

FIND: (a) Evaporation rate from a water film on the surface, (b) Steady-state film temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (b) Constant properties, (c) Negligible radiation, (d) Heat and mass transfer analogy is applicable.

PROPERTIES: Table A-4, Air (300K, 1 atm): $k = 0.0263 \text{ W/m}\cdot\text{K}$, $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 0.707$; Table A-6, Water ($T_s \approx 280\text{K}$): $\nu_g = 130.4 \text{ m}^3/\text{kg}$, $h_{fg} = 2485 \text{ kJ/kg}$; Table A-8, Water-air ($T \approx 298\text{K}$): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: (a) The mass evaporation rate is

$$\dot{m}_{\text{evap}} = n_A = \bar{h}_m A [\rho_{A,\text{sat}}(T_s) - \phi_{\infty} \rho_{A,\text{sat}}(T_{\infty})] = \bar{h}_m A \rho_{A,\text{sat}}(T_s).$$

From the heat and mass transfer analogy: $\bar{\text{Sh}}_L = 0.43 \text{Re}_L^{0.58} \text{Sc}^{0.4}$

$$\text{Re}_L = \frac{VL}{\nu} = \frac{(10 \text{ m/s}) 1 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 6.29 \times 10^5 \quad \text{Sc} = \frac{\nu}{D_{AB}} = \frac{15.89 \times 10^{-6} \text{ m}^2/\text{s}}{26 \times 10^{-6} \text{ m}^2/\text{s}} = 0.61$$

$$\bar{\text{Sh}}_L = 0.43 (6.29 \times 10^5)^{0.58} (0.61)^{0.4} = 814$$

$$\bar{h}_m = \frac{D_{AB}}{L} \bar{\text{Sh}}_L = \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{1 \text{ m}} (814) = 0.0212 \text{ m/s}$$

$$\rho_{A,\text{sat}}(T_s) = \nu_g(T_s)^{-1} = 0.0077 \text{ kg/m}^3.$$

$$\text{Hence, } \dot{m}_{\text{evap}} = 0.0212 \text{ m/s} \times 1 \text{ m}^2 \times 0.0077 \text{ kg/m}^3 = 1.63 \times 10^{-4} \text{ kg/s.} \quad <$$

(b) From a surface energy balance, $q''_{\text{conv}} = q''_{\text{evap}}$, or

$$\bar{h}_L (T_{\infty} - T_s) = \dot{m}_{\text{evap}}'' h_{fg} \quad T_s = T_{\infty} - \frac{(\dot{m}_{\text{evap}}'' h_{fg})}{\bar{h}_L}.$$

$$\text{With } \bar{\text{Nu}}_L = 0.43 (6.29 \times 10^5)^{0.58} (0.707)^{0.4} = 864$$

$$\bar{h}_L = \frac{k}{L} \bar{\text{Nu}}_L = \frac{0.0263 \text{ W/m}\cdot\text{K}}{1 \text{ m}} 864 = 22.7 \text{ W/m}^2 \cdot \text{K}.$$

$$\text{Hence, } T_s = 300\text{K} - \frac{1.63 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2 (2.485 \times 10^6 \text{ J/kg})}{22.7 \text{ W/m}^2 \cdot \text{K}} = 282.2\text{K.} \quad <$$

COMMENTS: The saturated vapor density, $\rho_{A,\text{sat}}$, is strongly temperature dependent, and if the initial guess of T_s needed for its evaluation differed from the above result by more than a few degrees, the density would have to be evaluated at the new temperature and the calculations repeated.

PROBLEM 6.51

KNOWN: Dimensions of rectangular naphthalene rod. Velocity and temperature of air flow. Molecular weight and saturation pressure of naphthalene.

FIND: Mass loss after 30 minutes.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Mass loss is small, so dimensions remain unchanged, (3) Viscosity of air-naphthalene mixture is approximately that of air.

PROPERTIES: Table A-4, Air (300 K): $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$. Table A-8, Naphthalene in air, (300 K): $D_{AB} = 0.62 \times 10^{-5} \text{ m}^2/\text{s}$, $Sc = \nu/D_{AB} = 2.56$.

ANALYSIS: We will use the heat and mass transfer analogy, with the Nusselt number correlation known from Problem 6.10 to be of the form

$$Nu_d = C Re_d^m Pr^{1/3}$$

Then invoking Equation 6.59,

$$Sh_d = C Re_d^m Sc^{1/3} = h_m d / D_{AB}$$

Now $Re_d = Vd/\nu = 10 \text{ m/s} \times 0.03 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 18,880$. We find the values of C and m from Problem 6.10 with $c/d = 0.33$, for the front, sides, and back of the rod:

	C	m	Sh_d	$h_m(\text{m/s})$
front	0.674	1/2	126.7	0.0262
sides	0.153	2/3	148.5	0.0307
back	0.174	2/3	168.8	0.0349

The average mass transfer coefficient is

$$\begin{aligned} \bar{h}_m &= (h_{m,\text{front}}d + 2h_{m,\text{side}}c + h_{m,\text{back}}d)/(2d + 2c) \\ &= \frac{0.0262 \text{ m/s} \times 0.03 \text{ m} + 2 \times 0.0307 \text{ m/s} \times 0.01 \text{ m} + 0.0349 \text{ m/s} \times 0.03 \text{ m}}{2 \times 0.03 \text{ m} + 2 \times 0.01 \text{ m}} \\ &= 0.0306 \text{ m/s} \end{aligned}$$

Then the mass loss can be found from

$$\Delta m = n_A \Delta t = \bar{h}_m A_{\text{tot}} (\rho_{A,s} - \rho_{A,\infty}) \Delta t$$

Continued...

PROBLEM 6.51 (Cont.)

Here $\rho_{A,\infty} = 0$ and $\rho_{A,s}$ can be found from the saturation pressure, using the ideal gas law:

$$\begin{aligned}\rho_{A,s} &= \frac{\rho_{A,\text{sat}}}{R_i T_s} = \frac{\rho_{A,\text{sat}} \mathcal{M}_A}{\mathcal{R} T_s} \\ &= \frac{1.33 \times 10^{-4} \text{ bar} \times 128.16 \text{ kg/kmol}}{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} \times 300 \text{ K}} \\ &= 6.83 \times 10^{-4} \text{ kg/m}^3\end{aligned}$$

Thus, finally,

$$\begin{aligned}\Delta m &= 0.0306 \text{ m/s} \times (2 \times 0.03 \text{ m} + 2 \times 0.01 \text{ m}) \times 0.5 \text{ m} \\ &\quad \times (6.83 \times 10^{-4} - 0) \text{ kg/m}^3 \times 30 \text{ min} \times 60 \text{ s/min} \\ &= 1.50 \times 10^{-3} \text{ kg}\end{aligned}$$

<

COMMENTS: The average depth of surface recession is given by $\delta = \overline{h_m}(\rho_{A,s} - \rho_{A,\infty})\Delta t/\rho_{A,\text{sol}}$ where $\rho_{A,\text{sol}}$ is the density of solid naphthalene, $\rho_{A,\text{sol}} = 1025 \text{ kg/m}^3$. Thus $\delta = 37 \text{ }\mu\text{m}$ and the assumption that the dimensions remain unchanged is good.

PROBLEM 6.52

KNOWN: Surface area and temperature of a coated turbine blade. Temperature and pressure of air flow over the blade. Molecular weight and saturation vapor pressure of the naphthalene coating. Duration of air flow and corresponding mass loss of naphthalene due to sublimation.

FIND: Average convection heat transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Applicability of heat and mass transfer analogy, (2) Negligible change in A_s due to mass loss, (3) Naphthalene vapor behaves as an ideal gas, (4) Solid/vapor equilibrium at surface of coating, (5) Negligible vapor density in freestream of air flow.

PROPERTIES: Table A-4, Air ($T = 300\text{K}$): $\rho = 1.161 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg}\cdot\text{K}$, $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$. Table A-8, Naphthalene vapor/air ($T = 300\text{K}$): $D_{AB} = 0.62 \times 10^{-5} \text{ m}^2/\text{s}$.

ANALYSIS: From the rate equation for convection mass transfer, the average convection mass transfer coefficient may be expressed as

$$\bar{h}_m = \frac{n_A}{A_s (\rho_{A,s} - \rho_{A,\infty})} = \frac{\Delta m / \Delta t}{A_s \rho_{A,s}}$$

where

$$\rho_{A,s} = \rho_{A,\text{sat}}(T_s) = \frac{\mathcal{M}_A p_{A,\text{sat}}}{\mathcal{R} T_s} = \frac{(128.16 \text{ kg/kmol}) (1.33 \times 10^{-4} \text{ bar})}{0.08314 \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} (300\text{K})} = 6.83 \times 10^{-4} \text{ kg/m}^3$$

Hence,

$$\bar{h}_m = \frac{0.008 \text{ kg} / (30 \text{ min} \times 60 \text{ s/min})}{0.05 \text{ m}^2 (6.83 \times 10^{-4} \text{ kg/m}^3)} = 0.13 \text{ m/s}$$

Using the heat and mass transfer analogy with $n = 1/3$, we then obtain

$$\begin{aligned} \bar{h} &= \bar{h}_m \rho c_p \text{Le}^{2/3} = \bar{h}_m \rho c_p \left(\frac{\alpha}{D_{AB}} \right)^{2/3} = 0.130 \text{ m/s} (1.161 \text{ kg/m}^3) \times \\ &1007 \text{ J/kg} \cdot \text{K} \left(22.5 \times 10^{-6} / 0.62 \times 10^{-5} \right)^{2/3} = 359 \text{ W/m}^2 \cdot \text{K} \end{aligned} \quad <$$

COMMENTS: The naphthalene sublimation technique has been used extensively to determine convection coefficients associated with complex flows and geometries.

PROBLEM 6.53

KNOWN: Half-scale naphthalene model of human head. Velocity and temperature of air flow while skiing. Temperature of air in wind tunnel. Depth of recession after 120 min for three locations. Density of solid naphthalene.

FIND: (a) Required wind tunnel velocity, (b) Heat transfer coefficients for full-scale head in skiing conditions, (c) Explain if uncovered regions would have same heat transfer coefficient when headgear is in place.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Pr and Sc are raised to the one-third power in the heat and mass transfer correlations, (3) The properties of the air-naphthalene mixture are approximately those of air, (4) Properties can be evaluated at T_∞ under the skiing conditions.

PROPERTIES: Table A-4, Air ($-13^\circ\text{C} = 260 \text{ K}$): $\nu = 12.33 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 23.1 \times 10^{-3} \text{ W/m}\cdot\text{K}$. Air (300 K): $\rho = 1.161 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg}\cdot\text{K}$, $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 26.3 \times 10^{-3} \text{ W/m}\cdot\text{K}$, $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$. Table A-8, Naphthalene in air, (300 K): $D_{AB} = 0.62 \times 10^{-5} \text{ m}^2/\text{s}$.

ANALYSIS: (a) In order for the results of the wind tunnel test to be directly applicable to the skiing conditions, the Reynolds numbers must be the same:

$$\text{Re}_s = \text{Re}_w \quad V_s L_s / \nu_s = V_w L_w / \nu_w$$

$$V_w = V_s \frac{L_s}{L_w} \frac{\nu_w}{\nu_s} = 10 \text{ m/s} \times 2 \times \frac{15.89 \times 10^{-6} \text{ m}^2/\text{s}}{12.33 \times 10^{-6} \text{ m}^2/\text{s}} = 25.8 \text{ m/s} \quad <$$

(b) The mass flux and mass transfer coefficient can be found from knowledge of the recession depth:

$$n''_A = \rho_{A,\text{sol}} \delta / \Delta t$$

$$h_m = n''_A / (\rho_{A,s} - \rho_{A,\infty}) = \rho_{A,\text{sol}} \delta / (\rho_{A,s} - \rho_{A,\infty}) \Delta t$$

where $\rho_{A,\infty} = 0$ and $\rho_{A,s}$ can be found from the saturation pressure and molecular weight (see Problem 6.51) using the ideal gas law.

$$\rho_{A,s} = \frac{\rho_{A,\text{sat}} \mathcal{M}_A}{\mathcal{R} T_s} = \frac{1.33 \times 10^{-4} \text{ bars} \times 128.16 \text{ kg/kmol}}{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} \times 300 \text{ K}} = 6.83 \times 10^{-4} \text{ kg/m}^3 \quad <$$

Continued...

PROBLEM 6.53 (Cont.)

Thus, with $\delta_1 = 0.1$ mm,

$$h_{m,1} = 1025 \text{ kg/m}^3 \times 10^{-4} \text{ m} / (6.83 \times 10^{-4} \text{ kg/m}^3 \times 120 \text{ min} \times 60 \text{ s/min}) = 2.08 \times 10^{-2} \text{ m/s}$$

Similarly for the other two locations,

$$h_{m,2} = 6.67 \times 10^{-2} \text{ m/s}, \quad h_{m,3} = 1.33 \times 10^{-1} \text{ m/s}$$

The heat transfer coefficients can then be found from the heat and mass transfer analogy as stated in Equation 6.60.

$$h = h_m \rho c_p \text{Le}^{1-n}$$

where $n = 1/3$ and

$$\text{Le} = \alpha / D_{AB} = (22.5 \times 10^{-6} \text{ m}^2/\text{s}) / (0.62 \times 10^{-5} \text{ m}^2/\text{s}) = 3.63$$

Thus at location 1,

$$h_1 = 2.08 \times 10^{-2} \text{ m/s} \times 1.161 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \times (3.63)^{2/3} = 57.4 \text{ W/m}^2 \cdot \text{K}$$

And for the other two locations,

$$h_2 = 184 \text{ W/m}^2 \cdot \text{K}, \quad h_3 = 368 \text{ W/m}^2 \cdot \text{K}$$

These values are for the half-scale model. Since the Reynolds number is the same in the wind tunnel as in the skiing conditions, the local Nusselt numbers are also the same (see Equation 6.49), thus

$$\begin{aligned} \text{Nu}_s &= \text{Nu}_w & h_s L_s / k_s &= h_w L_w / k_w \\ h_s &= h_w \frac{L_w}{L_s} \frac{k_s}{k_w} = h_w \times 1/2 \times \frac{23.1 \times 10^{-3} \text{ W/m} \cdot \text{K}}{26.3 \times 10^{-3} \text{ W/m} \cdot \text{K}} \end{aligned}$$

Thus

$$h_{s1} = h_{w1} \times 0.439 = 57.4 \text{ W/m}^2 \cdot \text{K} \times 0.439 = 25.2 \text{ W/m}^2 \cdot \text{K} \quad <$$

And similarly

$$h_{s,2} = 80.8 \text{ W/m}^2 \cdot \text{K}, \quad h_{s,3} = 162 \text{ W/m}^2 \cdot \text{K} \quad <$$

(c) When the headgear is in place, it will change the geometry of the surface and therefore change the heat transfer coefficients. The regions that are left uncovered will be recessed relative to the rest of the surface. This will probably reduce the local velocity near the surface slightly and reduce the local heat transfer coefficient.

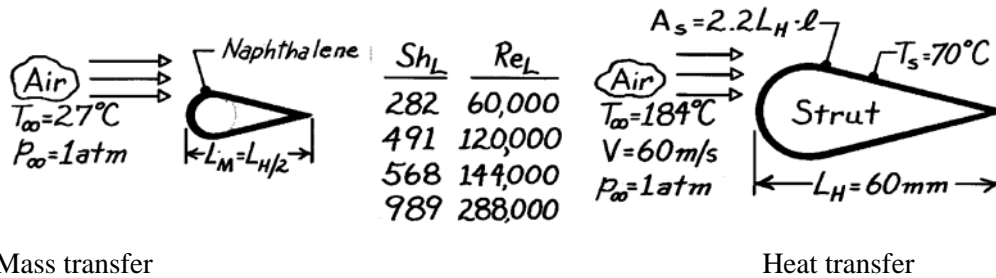

COMMENTS: (1) The properties should be evaluated at the “film temperature,” $T_f = (T_s + T_\infty)/2$. In the wind tunnel the conditions are isothermal, but in the ski conditions they are not. However the surface temperature is unknown and cannot be found without a more complex analysis of heat transfer in the body and the headgear (when present). (2) Heat loss is not the only consideration when designing winter clothing. Comfort is also important and exposed areas could be uncomfortably cold, even though areas with small heat transfer coefficients will be warmer than those with larger coefficients.

PROBLEM 6.54

KNOWN: Mass transfer experimental results on a half-sized model representing an engine strut.

FIND: (a) The coefficients C and m of the correlation $\overline{Sh}_L = C Re_L^m Sc^{1/3}$ for the mass transfer results, (b) Average heat transfer coefficient, \bar{h} , for the full-sized strut with prescribed operating conditions, (c) Change in total heat rate if characteristic length L_H is doubled.

SCHEMATIC:

Mass transfer

Heat transfer

ASSUMPTIONS: Analogy exists between heat and mass transfer.

PROPERTIES: Table A-4, Air ($\bar{T} = (T_\infty + T_s)/2 = 400\text{K}$, 1 atm): $\nu = 26.41 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0338 \text{ W/m}\cdot\text{K}$, $Pr = 0.690$; ($\bar{T} = 300\text{K}$): $\nu_B = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$; Table A-8, Naphthalene-air (300K, 1 atm): $D_{AB} = 0.62 \times 10^{-5} \text{ m}^2/\text{s}$, $Sc = \nu_B / D_{AB} = 15.89 \times 10^{-6} \text{ m}^2/\text{s} / 0.62 \times 10^{-5} \text{ m}^2/\text{s} = 2.56$.

ANALYSIS: (a) The correlation for the mass transfer experimental results is of the form $\overline{Sh}_L = C Re_L^m Sc^{1/3}$. The constants C, m may be evaluated from two data sets of \overline{Sh}_L and Re_L ; choosing the middle sets (2,3):

$$\frac{(\overline{Sh}_L)_2}{(\overline{Sh}_L)_3} = \frac{(Re_L)_2^m}{(Re_L)_3^m} \text{ or } m = \frac{\log [(\overline{Sh}_L)_2 / (\overline{Sh}_L)_3]}{\log [(Re_L)_2 / (Re_L)_3]} = \frac{\log [491/568]}{\log [120,000/144,000]} = 0.80. \quad <$$

$$\text{Then, using set 2, find } C = \frac{(\overline{Sh}_L)_2}{Re_L^m Sc^{1/3}} = \frac{491}{(120,000)^{0.8} 2.56^{1/3}} = 0.031. \quad <$$

(b) For the heat transfer analysis of the strut, the correlation will be of the form

$\overline{Nu}_L = \bar{h}_L \cdot L_H / k = 0.031 Re_L^{0.8} Pr^{1/3}$ where $Re_L = V L_H / \nu$ and the constants C, m were determined in Part (a). Substituting numerical values,

$$\bar{h}_L = \overline{Nu}_L \cdot \frac{k}{L_H} = 0.031 \left[\frac{60 \text{ m/s} \times 0.06 \text{ m}}{26.41 \times 10^{-6} \text{ m}^2/\text{s}} \right]^{0.8} 0.690^{1/3} \frac{0.0338 \text{ W/m}\cdot\text{K}}{0.06 \text{ m}} = 198 \text{ W/m}^2 \cdot \text{K}. \quad <$$

(c) The total heat rate for the strut of characteristic length L_H is $q = \bar{h} A_s (T_s - T_\infty)$, where $A_s = 2.2 L_H \cdot l$ and

$$\bar{h} \sim \overline{Nu}_L \cdot L_H^{-1} \sim Re_L^{0.8} \cdot L_H^{-1} \sim L_H^{0.8} \cdot L_H^{-1} \sim L_H^{-0.2} \quad A_s \sim L_H$$

Hence, $q \sim \bar{h} \cdot A_s \sim (L_H^{-0.2}) (L_H) \sim L_H^{0.8}$. If the characteristic length were doubled, the heat rate

would be increased by a factor of $(2)^{0.8} = 1.74$. <

PROBLEM 6.55

KNOWN: Boundary layer temperature distribution for flow of dry air over water film.

FIND: Evaporative mass flux and whether net energy transfer is to or from the water.

SCHEMATIC:

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Water is well insulated from below.

PROPERTIES: Table A-4, Air ($T_s = 300\text{K}$, 1 atm): $k = 0.0263\text{ W/m}\cdot\text{K}$; Table A-6, Water vapor ($T_s = 300\text{K}$): $\rho_{A,s} = v_g^{-1} = 0.0256\text{ kg/m}^3$, $h_{fg} = 2.438 \times 10^6\text{ J/kg}$; Table A-8, Air-water vapor ($T_s = 300\text{K}$): $D_{AB} = 0.26 \times 10^{-4}\text{ m}^2/\text{s}$.

ANALYSIS: From the heat and mass transfer analogy,

$$\frac{\rho_A - \rho_{A,s}}{\rho_{A,\infty} - \rho_{A,s}} = 1 - \exp\left[-Sc \frac{u_\infty y}{\nu}\right].$$

Using Fick's law at the surface ($y = 0$), the species flux is

$$\begin{aligned} n_A'' &= -D_{AB} \left. \frac{\partial \rho_A}{\partial y} \right|_{y=0} = +\rho_{A,s} D_{AB} Sc \frac{u_\infty}{\nu} \\ n_A'' &= 0.0256\text{ kg/m}^3 \times 0.26 \times 10^{-4}\text{ m}^2/\text{s} \times (0.6) 5000\text{ m}^{-1} = 2.00 \times 10^{-3}\text{ kg/s}\cdot\text{m}^2. \end{aligned}$$

The net heat flux to the water has the form

$$q_{\text{net}}'' = q_{\text{conv}}'' - q_{\text{evap}}'' = +k \left. \frac{\partial T}{\partial y} \right|_{y=0} - n_A'' h_{fg} = k(T_\infty - T_s) Pr \frac{u_\infty}{\nu} - n_A'' h_{fg}$$

and substituting numerical values, find

$$\begin{aligned} q_{\text{net}}'' &= 0.0263 \frac{\text{W}}{\text{m}\cdot\text{K}} (100\text{K}) 0.7 \times 5000\text{ m}^{-1} - 2 \times 10^{-3} \frac{\text{kg}}{\text{s}\cdot\text{m}^2} \times 2.438 \times 10^6\text{ J/kg} \\ q_{\text{net}}'' &= 9205\text{ W/m}^2 - 4876\text{ W/m}^2 = 4329\text{ W/m}^2. \end{aligned}$$

Since $q_{\text{net}}'' > 0$, the net heat transfer is to the water. <

COMMENTS: Note use of properties (D_{AB} and k) evaluated at T_s to determine surface fluxes.

PROBLEM 6.56

KNOWN: Distribution of local convection heat transfer coefficient for obstructed flow over a flat plate with surface and air temperatures of 310K and 290K, respectively.

FIND: Average convection mass transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: Heat and mass transfer analogy is applicable.

PROPERTIES: Table A-4, Air ($T_f = (T_s + T_\infty)/2 = (310 + 290)K/2 = 300K$, 1 atm):

$k = 0.0263 \text{ W/m} \cdot \text{K}$, $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.707$. Table A-8, Air-naphthalene (300K, 1 atm): $D_{AB} = 0.62 \times 10^{-5} \text{ m}^2/\text{s}$, $Sc = \nu/D_{AB} = 2.56$.

ANALYSIS: The average heat transfer coefficient is

$$\bar{h}_L = \frac{1}{L} \int_0^L h_x dx = \frac{1}{L} \int_0^L (0.7 + 13.6x - 3.4x^2) dx$$

$$\bar{h}_L = 0.7 + 6.8L - 1.13L^2 = 10.9 \text{ W/m}^2 \cdot \text{K}.$$

Applying the heat and mass transfer analogy with $n = 1/3$, Equation 6.59 yields

$$\frac{\bar{Nu}_L}{Pr^{1/3}} = \frac{\bar{Sh}_L}{Sc^{1/3}}$$

Hence,

$$\frac{\bar{h}_{m,L} L}{D_{AB}} = \frac{\bar{h}_L L}{k} \frac{Sc^{1/3}}{Pr^{1/3}}$$

$$\bar{h}_{m,L} = \bar{h}_L \frac{D_{AB}}{k} \frac{Sc^{1/3}}{Pr^{1/3}} = 10.9 \text{ W/m}^2 \cdot \text{K} \frac{0.62 \times 10^{-5} \text{ m}^2/\text{s}}{0.0263 \text{ W/m} \cdot \text{K}} \left(\frac{2.56}{0.707} \right)^{1/3}$$

$$\bar{h}_{m,L} = 0.00395 \text{ m/s.} \quad <$$

COMMENTS: The naphthalene sublimation method provides a useful tool for determining local convection coefficients.

PROBLEM 6.57

KNOWN: Radial distribution of local Sherwood number for uniform flow normal to a circular disk.

FIND: (a) Expression for average Nusselt number. (b) Heat rate for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Applicability of heat and mass transfer analogy.

PROPERTIES: Table A-4, Air ($\bar{T} = 75^\circ\text{C} = 348\text{ K}$): $k = 0.0299\text{ W/m}\cdot\text{K}$, $Pr = 0.70$.

ANALYSIS: (a) From the heat and mass transfer analogy, Equation 6.57,

$$\frac{\overline{Nu}_D}{Pr^{0.36}} = \frac{\overline{Sh}_D}{Sc^{0.36}}$$

where

$$\begin{aligned} \overline{Sh}_D &= \frac{1}{A_s} \int_{A_s} Sh_D(r) dA_s = \frac{Sh_o}{\pi r_o^2} 2\pi \int_0^{r_o} [1 + a(r/r_o)^n] r dr \\ \overline{Sh}_D &= \frac{2Sh_o}{r_o^2} \left[\frac{r^2}{2} + \frac{a r^{n+2}}{(n+2)r_o^n} \right]_0^{r_o} = Sh_o [1 + 2a/(n+2)] \end{aligned}$$

Hence,

$$\overline{Nu}_D = 0.814 [1 + 2a/(n+2)] Re_D^{1/2} Pr^{0.36}.$$

(b) The heat rate for these conditions is

$$\begin{aligned} q &= \bar{h}A(T_s - T_\infty) = 0.814 [1 + 2a/(n+2)] \frac{k}{D} Re_D^{1/2} Pr^{0.36} \left(\frac{\pi D^2}{4} \right) (T_s - T_\infty) \\ q &= 0.814 (1 + 2.4/7.5) 0.0299\text{ W/m}\cdot\text{K} (\pi 0.02\text{ m}/4) (5 \times 10^4)^{1/2} (0.7)^{0.36} (100^\circ\text{C}) \\ q &= 9.92\text{ W}. \end{aligned}$$

COMMENTS: The increase in $h(r)$ with r may be explained in terms of the sharp turn which the boundary layer flow must make around the edge of the disk. The boundary layer accelerates and its thickness decreases as it makes the turn, causing the local convection coefficient to increase.

PROBLEM 6.58

KNOWN: Convection heat transfer correlation for wetted surface of a sand grouse. Initial water content of surface. Velocity of bird and ambient air conditions.

FIND: Flight distance for depletion of 50% of initial water content.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as a perfect gas, (3) Constant properties, (4) Applicability of heat and mass transfer analogy.

PROPERTIES: Air (given): $\nu = 16.7 \times 10^{-6} \text{ m}^2/\text{s}$; Air-water vapor (given):

$D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$; Table A-6, Water vapor ($T_s = 305 \text{ K}$): $\nu_g = 29.74 \text{ m}^3/\text{kg}$; ($T_s = 310 \text{ K}$), $\nu_g = 22.93 \text{ m}^3/\text{kg}$.

ANALYSIS: The maximum flight distance is

$$X_{\max} = V t_{\max}$$

where the time to deplete 50% of the initial water content ΔM is

$$t_{\max} = \frac{\Delta M}{\dot{m}_{\text{evap}}} = \frac{\Delta M}{\bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty})}$$

The mass transfer coefficient is

$$\begin{aligned} \bar{h}_m &= \bar{\text{Sh}}_L \frac{D_{AB}}{L} = 0.034 \text{Re}_L^{4/5} \text{Sc}^{1/3} \frac{D_{AB}}{L} \\ \text{Sc} &= \nu/D_{AB} = 0.642, \quad L = (A_s)^{1/2} = 0.2 \text{ m} \\ \text{Re}_L &= \frac{VL}{\nu} = \frac{30 \text{ m/s} \times 0.2 \text{ m}}{16.7 \times 10^{-6} \text{ m}^2/\text{s}} = 3.59 \times 10^5 \\ \bar{h}_m &= 0.034 (3.59 \times 10^5)^{4/5} (0.642)^{1/3} (0.26 \times 10^{-4} \text{ m}^2/\text{s}/0.2 \text{ m}) = 0.106 \text{ m/s}. \end{aligned}$$

Hence,

$$t_{\max} = \frac{0.025 \text{ kg}}{0.106 \text{ m/s} (0.04 \text{ m}^2) \left[(29.74)^{-1} - 0.25(22.93)^{-1} \right] \text{ kg/m}^3} = 259 \text{ s}$$

$$X_{\max} = 30 \text{ m/s} (259 \text{ s}) = 7785 \text{ m} = 7.78 \text{ km.} \quad <$$

COMMENTS: Evaporative heat loss is balanced by convection heat transfer from air.

Hence, $T_s < T_{\infty}$.

PROBLEM 6.59

KNOWN: Water-soaked paper towel experiences simultaneous heat and mass transfer while subjected to parallel flow of air, irradiation from a radiant lamp bank, and radiation exchange with surroundings. Average convection coefficient estimated as $\bar{h} = 28.7 \text{ W/m}^2 \cdot \text{K}$.

FIND: (a) Rate at which water evaporates from the towel, n_A (kg/s), and (b) The net rate of radiation transfer, q_{rad} (W), to the towel. Determine the irradiation G (W/m^2).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as an ideal gas, (3) Constant properties, (4) Towel experiences radiation exchange with the large surroundings as well as irradiation from the lamps, (5) Negligible heat transfer from the bottom side of the towel, and (6) Applicability of the heat-mass transfer analogy.

PROPERTIES: Table A.4, Air ($T_f = 300 \text{ K}$): $\rho = 1.1614 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg} \cdot \text{K}$, $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$; Table A.6, Water (310 K): $\rho_{A,s} = \rho_g = 1/v_g = 1/22.93 = 0.0436 \text{ kg/m}^3$, $h_{fg} = 2414 \text{ kJ/kg}$. Table A.8, Water-Air ($T \approx 300 \text{ K}$): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: (a) The evaporation rate from the towel is

$$n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty})$$

where \bar{h}_m can be determined from the heat-mass transfer analogy, Eq. 6.60, with $n = 1/3$,

$$\frac{h}{h_m} = \rho c_p \text{Le}^{2/3} = \rho c_p \left(\frac{\alpha}{D_{AB}} \right)^{2/3} = 1.1614 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \left(\frac{22.5 \times 10^{-6}}{0.26 \times 10^{-4}} \right)^{2/3} = 1476 \text{ J/m}^3 \cdot \text{K}$$

$$h_m = 28.7 \text{ W/m}^2 \cdot \text{K} / 1476 \text{ J/m}^3 \cdot \text{K} = 0.0194 \text{ m/s}$$

The evaporation rate is

$$n_A = 0.0194 \text{ m/s} \times (0.0925 \times 0.0925) \text{ m}^2 (0.0436 - 0) \text{ kg/m}^3 = 7.25 \times 10^{-6} \text{ kg/s} \quad <$$

(b) Performing an energy balance on the towel considering processes of evaporation, convection and radiation, find

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = q_{\text{conv}} - q_{\text{evap}} + q_{\text{rad}} = 0$$

$$\bar{h} A_s (T_{\infty} - T_s) - n_A h_{fg} + q_{\text{rad}} = 0$$

$$q_{\text{rad}} = 7.25 \times 10^{-6} \text{ kg/s} \times 2414 \times 10^3 \text{ J/kg} - 28.7 \text{ W/m}^2 (0.0925 \text{ m})^2 (290 - 310) \text{ K}$$

$$q_{\text{rad}} = 17.5 \text{ W} + 4.91 \text{ W} = 22.4 \text{ W} \quad <$$

Continued...

PROBLEM 6.59 (Cont.)

The net radiation heat transfer to the towel is comprised of the absorbed irradiation and the net exchange between the surroundings and the towel,

$$q_{\text{rad}} = \alpha G A_s + \varepsilon A_s \sigma (T_{\text{sur}}^4 - T_s^4)$$

$$22.4 \text{ W} = 0.96 G (0.0925 \text{ m})^2 + 0.96 \times (0.0925 \text{ m})^2 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300^4 - 310^4) \text{ K}^4$$

Solving, find the irradiation from the lamps,

$$G = 2791 \text{ W/m}^2.$$

<

COMMENTS: (1) From the energy balance in Part (b), note that the heat rate by convection is considerably smaller than that by evaporation.

(2) As we'll learn in Chapter 12, the lamp irradiation found in Part (c) is approximately 2 times that of solar irradiation to the earth's surface.

PROBLEM 6.60

KNOWN: Thin layer of water on concrete surface experiences evaporation, convection with ambient air, and radiation exchange with the sky. Average convection coefficient estimated as $\bar{h} = 53 \text{ W/m}^2\cdot\text{K}$.

FIND: (a) Heat fluxes associated with convection, q''_{conv} , evaporation, q''_{evap} , and radiation exchange with the sky, q''_{rad} , (b) Use results to explain why the concrete is wet instead of dry, and (c) Direction of heat flow and the heat flux by conduction into or out of the concrete.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as an ideal gas, (3) Constant properties, (4) Water surface is small compare to large, isothermal surroundings (sky), and (4) Applicability of the heat-mass transfer analogy.

PROPERTIES: Table A.4, Air ($T_f = (T_\infty + T_s)/2 = 282.5 \text{ K}$): $\rho = 1.243 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg}\cdot\text{K}$, $\alpha = 2.019 \times 10^5 \text{ m}^2/\text{s}$; Table A.8, Water-air ($T_f = 282.5 \text{ K}$): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ($282.5/298$)^{3/2} = $0.24 \times 10^{-4} \text{ m}^2/\text{s}$; Table A.6, Water ($T_s = 275 \text{ K}$): $\rho_{A,s} = \rho_g = 1/v_g = 1/181.7 = 0.0055 \text{ kg/m}^3$, $h_{fg} = 2497 \text{ kJ/kg}$; Table A.6, Water ($T_\infty = 290 \text{ K}$): $\rho_{A,\infty} = 1/69.7 = 0.0143 \text{ kg/m}^3$.

ANALYSIS: (a) The heat fluxes associated with the processes shown on the schematic are

Convection:

$$q''_{\text{conv}} = \bar{h}(T_\infty - T_s) = 53 \text{ W/m}^2 \cdot \text{K} (290 - 275) \text{ K} = +795 \text{ W/m}^2 \quad <$$

Radiation Exchange:

$$q''_{\text{rad}} = \epsilon \sigma (T_s^4 - T_{\text{sky}}^4) = 0.96 \times 5.76 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (275^4 - 240^4) \text{ K}^4 = +131 \text{ W/m}^2 \quad <$$

Evaporation:

$$q''_{\text{evap}} = n''_A h_{fg} = -2.255 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2 \times 2497 \times 10^3 \text{ J/kg} = -563.1 \text{ W/m}^2 \quad <$$

where the evaporation rate *from* the surface is

$$n''_A = \bar{h}_m (\rho_{A,s} - \rho_{A,\infty}) = 0.050 \text{ m/s} (0.0055 - 0.7 \times 0.0143) \text{ kg/m}^3 = -2.255 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2$$

Continued...

PROBLEM 6.60 (Cont.)

and where the mass transfer coefficient is evaluated from the heat-mass transfer analogy, Eq. 6.60, with $n = 1/3$,

$$\frac{\bar{h}}{\bar{h}_m} = \rho c_p Le^{2/3} = \rho c_p \left(\frac{\alpha}{D_{AB}} \right)^{2/3} = 1.243 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \left(\frac{2.019 \times 10^{-5}}{0.26 \times 10^{-4}} \right)^{2/3}$$

$$\frac{\bar{h}}{\bar{h}_m} = 1058 \text{ J/m}^3 \cdot \text{K}$$

$$\bar{h}_m = 53 \text{ W/m}^2 \cdot \text{K} / 1058 \text{ J/m}^3 \cdot \text{K} = 0.050 \text{ m/s}$$

(b) From the foregoing evaporation calculations, note that water vapor from the air is condensing on the liquid water layer. That is, vapor is being transported to the surface, explaining why the concrete surface is wet, even without rain.

(c) From an overall energy balance on the water film considering conduction in the concrete as shown in the schematic,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$$

$$q''_{\text{conv}} - q''_{\text{evap}} - q''_{\text{rad}} - q''_{\text{cond}} = 0$$

$$q''_{\text{cond}} = q''_{\text{conv}} - q''_{\text{evap}} - q''_{\text{rad}}$$

$$q''_{\text{cond}} = 1795 \text{ W/m}^2 - (-563.1 \text{ W/m}^2) - (+131 \text{ W/m}^2) = 1227 \text{ W/m}^2 \quad <$$

The heat flux by conduction is *into* the concrete.

PROBLEM 6.61

KNOWN: Heater power required to maintain wetted (water) plate at 27°C, and average convection coefficient for specified dry air temperature, case (a).

FIND: Heater power required to maintain the plate at 37°C for the same dry air temperature if the convection coefficients remain unchanged, case (b).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Convection coefficients unchanged for different plate temperatures, (3) Air stream is dry at atmospheric pressure, and (4) Negligible heat transfer from the bottom side of the plate.

PROPERTIES: Table A-6, Water ($T_{s,a} = 27^\circ\text{C} = 300\text{ K}$): $\rho_{A,s} = 1/v_g = 0.02556\text{ kg/m}^3$, $h_{fg} = 2.438 \times 10^6\text{ J/kg}$; Water ($T_{s,b} = 37^\circ\text{C} = 310\text{ K}$): $\rho_{A,s} = 1/v_g = 0.04361\text{ kg/m}^3$, $h_{fg} = 2.414 \times 10^6\text{ J/kg}$.

ANALYSIS: For case (a) with $T_s = 27^\circ\text{C}$ and $P_e = 432\text{ W}$, perform an energy balance on the plate to determine the mass transfer coefficient h_m .

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$P_{e,a} - (q''_{evap} + q''_{cv})A_s = 0$$

Substituting the rate equations and appropriate properties,

$$P_{e,a} - \left[\bar{h}_m (\rho_{A,s} - \rho_{A,\infty}) h_{fg} + \bar{h} (T_{s,a} - T_\infty) \right] A_s = 0$$

$$432\text{ W} - \left[\bar{h}_m (0.02556\text{ kg/m}^3 - 0) \times 2.438 \times 10^6\text{ J/kg} + 20\text{ W/m}^2 \cdot \text{K} (27 - 32)\text{ K} \right] \times 0.2\text{ m}^2 = 0$$

where $\rho_{A,s}$ and h_{fg} are evaluated at $T_s = 27^\circ\text{C} = 300\text{ K}$. Find,

$$\bar{h}_m = 0.0363\text{ m/s}$$

For case (b), with $T_s = 37^\circ\text{C}$ and the same values for \bar{h} and \bar{h}_m , perform an energy balance to determine the heater power required to maintain this condition.

$$P_{e,b} - \left[\bar{h}_m (\rho_{A,s} - 0) h_{fg} + \bar{h} (T_{s,b} - T_\infty) \right] A_s = 0$$

$$P_{e,b} - \left[0.0363\text{ m/s} (0.04361 - 0)\text{ kg/m}^3 \times 2.414 \times 10^6\text{ J/kg} + 20\text{ W/m}^2 \cdot \text{K} (37 - 32)\text{ K} \right] \times 0.2\text{ m}^2 = 0$$

$$P_{e,b} = 784\text{ W}$$

where $\rho_{A,s}$ and h_{fg} are evaluated at $T_s = 37^\circ\text{C} = 310\text{ K}$.

<

PROBLEM 6.62

KNOWN: Dry air at 32°C flows over a wetted plate of width 1 m maintained at a surface temperature of 27°C by an embedded heater supplying 432 W.

FIND: (a) The evaporation rate of water from the plate, n_A (kg/h) and (b) The plate temperature T_s when all the water is evaporated, but the heater power remains the same.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as an ideal gas, (3) Constant properties, and (4) Applicability of the heat-mass transfer analogy.

PROPERTIES: Table A.4, Air ($T_f = (32 + 27)^\circ\text{C}/2 = 302.5\text{ K}$): $\rho = 1.153\text{ kg/m}^3$, $c_p = 1007\text{ J/kg}\cdot\text{K}$, $\alpha = 2.287 \times 10^{-5}\text{ m}^2/\text{s}$; Table A.8, Water-air ($T_f \approx 300\text{ K}$): $D_{AB} = 0.26 \times 10^{-4}\text{ m}^2/\text{s}$; Table A.6, Water ($T_s = 27^\circ\text{C} = 300\text{ K}$): $\rho_{A,s} = 1/v_g = 1/39.13 = 0.0256\text{ kg/m}^3$, $h_{fg} = 2438\text{ kJ/kg}$.

ANALYSIS: (a) Perform an energy balance on the wetted plate to obtain the evaporation rate, n_A .

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= 0 & P_e + q_{\text{conv}} - q_{\text{evap}} &= 0 \\ P_e + \bar{h}A_s(T_\infty - T_s) - n_A h_{fg} &= 0 \end{aligned} \quad (1)$$

In order to find \bar{h} , invoke the heat-mass transfer analogy, Eq. (6.60) with $n = 1/3$,

$$\frac{\bar{h}}{\bar{h}_m} = \rho c_p L e^{2/3} = \rho c_p \left(\frac{\alpha}{D_{AB}} \right)^{2/3} = 1.153\text{ kg/m}^3 \times 1007\text{ J/kg}\cdot\text{K} \left(\frac{2.287 \times 10^{-5}}{0.26 \times 10^{-4}} \right)^{2/3} = 1066\text{ J/m}^3 \cdot \text{K} \quad (2)$$

The evaporation rate equation

$$n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty})$$

Substituting Eqs. (2) and (3) into Eq. (1), find \bar{h}_m

$$P_e + (1066\text{ J/m}^3 \cdot \text{K} \bar{h}_m) A_s (T_\infty - T_s) - \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg} = 0 \quad (4)$$

$$432\text{ W} + \left[1066\text{ J/m}^3 \cdot \text{K} (32 - 27)\text{ K} - (0.0256 - 0)\text{ kg/m}^3 \times 2438 \times 10^3\text{ J/kg} \right] (0.200 \times 1)\text{ m}^2 \cdot \bar{h}_m = 0$$

$$432 + [5330 - 62,413] \times 0.20 \bar{h}_m = 0$$

$$\bar{h}_m = 0.0378\text{ m/s}$$

Using Eq. (3), find

$$n_A = 0.0378\text{ m/s} (0.200 \times 1)\text{ m}^2 (0.0256 - 0)\text{ kg/m}^3 = 1.94 \times 10^{-4}\text{ kg/s} = 0.70\text{ kg/h} \quad <$$

(b) When the plate is dry, all the power must be removed by convection,

$$P_e = q_{\text{conv}} = \bar{h} A_s (T_s - T_\infty)$$

Assuming \bar{h} is the same as for conditions with the wetted plate,

$$T_s = T_\infty + P_e / (\bar{h} A_s) = T_\infty + P_e / (1066 \bar{h}_m) A_s$$

$$T_s = 32^\circ\text{C} + 432\text{ W} / (1066 \times 0.0378\text{ W/m}^2 \cdot \text{K} \times 0.200\text{ m}^2) = 85.6^\circ\text{C} \quad <$$

PROBLEM 6.63

KNOWN: Surface temperature of a 20-mm diameter sphere is 32°C when dissipating 2.51 W in a dry air stream at 22°C.

FIND: Power required by the imbedded heater to maintain the sphere at 32°C if its outer surface has a thin porous covering saturated with water for the same dry air temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat and mass transfer analogy is applicable, (3) Heat transfer convection coefficient is the same for the dry and wet condition, and (3) Properties of air and the diffusion coefficient of the air-water vapor mixture evaluated at 300 K.

PROPERTIES: Table A-4, Air (300 K, 1 atm): $\rho = 1.1614 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg}\cdot\text{K}$, $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$; Table A-8, Water-air mixture (300 K, 1 atm): $D_{A-B} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$; Table A-4, Water (305 K, 1 atm): $\rho_{A,s} = 1/v_g = 0.03362 \text{ kg/m}^3$, $h_{fg} = 2.426 \times 10^6 \text{ J/kg}$.

ANALYSIS: For the *dry case (d)*, perform an energy balance on the sphere and calculate the heat transfer convection coefficient.

$$\dot{E}_{in} - \dot{E}_{out} = P_{e,d} - q_{cv} = 0 \quad P_{e,d} - \bar{h} A_s (T_s - T_\infty) = 0$$

$$2.51 \text{ W} - \bar{h} \pi (0.020 \text{ m})^2 \times (32 - 22) \text{ K} = 0 \quad \bar{h} = 200 \text{ W/m}^2 \cdot \text{K}$$

Use the heat-mass analogy, Eq. (6.60) with $n = 1/3$, to determine \bar{h}_m .

$$\frac{\bar{h}}{\bar{h}_m} = \rho c_p \left(\frac{\alpha}{D_{AB}} \right)^{2/3}$$

$$\frac{200 \text{ W/m}^2 \cdot \text{K}}{\bar{h}_m} = 1.1614 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \left(\frac{22.5 \times 10^{-6} \text{ m}^2/\text{s}}{0.26 \times 10^{-4} \text{ m}^2/\text{s}} \right)^{2/3}$$

$$\bar{h}_m = 0.188 \text{ m/s}$$

For the *wet case (w)*, perform an energy balance on the wetted sphere using values for \bar{h} and \bar{h}_m to determine the power required to maintain the same surface temperature.

$$\dot{E}_{in} - \dot{E}_{out} = P_{e,w} - q_{cv} - q_{evap} = 0$$

$$P_{e,w} - \left[\bar{h} (T_s - T_\infty) + \bar{h}_m (\rho_{A,s} - \rho_{A,\infty}) h_{fg} \right] A_s = 0$$

$$P_{e,w} - \left[200 \text{ W/m}^2 \cdot \text{K} (32 - 22) \text{ K} + 0.188 \text{ m/s} (0.03362 - 0) \text{ kg/m}^3 \times 2.426 \times 10^6 \text{ J/kg} \right] \pi (0.020 \text{ m})^2 = 0$$

$$P_{e,w} = 21.8 \text{ W}$$

<

COMMENTS: Note that $\rho_{A,s}$ and h_{fg} for the mass transfer rate equation are evaluated at $T_s = 32^\circ\text{C} = 305 \text{ K}$, not 300 K. The effect of evaporation is to require nearly 8.5 times more power to maintain the same surface temperature.

PROBLEM 6.64

KNOWN: Operating temperature, ambient air conditions and make-up water requirements for a hot tub.

FIND: Heater power required to maintain prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Side wall and bottom are adiabatic, (2) Heat and mass transfer analogy is applicable.

PROPERTIES: Table A-4, Air ($\bar{T} = 300\text{K}$, 1 atm): $\rho = 1.161\text{ kg/m}^3$, $c_p = 1007\text{ J/kg}\cdot\text{K}$, $\alpha = 22.5 \times 10^{-6}\text{ m}^2/\text{s}$; Table A-6, Sat. water vapor ($T = 310\text{K}$): $h_{fg} = 2414\text{ kJ/kg}$, $\rho_{A,\text{sat}}(T) = 1/v_g = (22.93\text{ m}^3/\text{kg})^{-1} = 0.0436\text{ kg/m}^3$; ($T_\infty = 290\text{K}$): $\rho_{A,\text{sat}}(T_\infty) = 1/v_g = (69.7\text{ m}^3/\text{kg})^{-1} = 0.0143\text{ kg/m}^3$; Table A-8, Air-water vapor (298K): $D_{AB} = 26 \times 10^{-6}\text{ m}^2/\text{s}$.

ANALYSIS: Applying an energy balance to the control volume,

$$q_{\text{elec}} = q_{\text{conv}} + q_{\text{evap}} = \bar{h} A (T - T_\infty) + \dot{m}_{\text{evap}} h_{fg}(T).$$

Obtain $\bar{h} A$ from Eq. 6.60 with $n = 1/3$,

$$\frac{\bar{h}}{h_m} = \frac{\bar{h}_A}{h_{m,A}} = \rho c_p \text{Le}^{2/3}$$

$$\bar{h} A = \bar{h}_m A \rho c_p \text{Le}^{2/3} = \frac{\dot{m}_{\text{evap}}}{\rho_{A,\text{sat}}(T) - \phi_\infty \rho_{A,\text{sat}}(T_\infty)} \rho c_p \text{Le}^{2/3}.$$

Substituting numerical values,

$$\text{Le} = \alpha/D_{AB} = (22.5 \times 10^{-6}\text{ m}^2/\text{s}) / 26 \times 10^{-6}\text{ m}^2/\text{s} = 0.865$$

$$\bar{h}_m A = \frac{10^{-3}\text{ kg/s}}{[0.0436 - 0.3 \times 0.0143]\text{ kg/m}^3} \cdot 1.161 \frac{\text{kg}}{\text{m}^3} \times 1007 \frac{\text{J}}{\text{kg}\cdot\text{K}} (0.865)^{2/3}$$

$$\bar{h} A = 27.0\text{ W/K}.$$

Hence, the required heater power is

$$q_{\text{elec}} = 27.0\text{ W/K} (310 - 290)\text{ K} + 10^{-3}\text{ kg/s} \times 2414\text{ kJ/kg} \times 1000\text{ J/kJ}$$

$$q_{\text{elec}} = (540 + 2414)\text{ W} = 2954\text{ W}.$$

<

COMMENTS: The evaporative heat loss is dominant.

PROBLEM 6.65

KNOWN: Water freezing under conditions for which the air temperature exceeds 0°C.

FIND: (a) Lowest air temperature, T_∞ , before freezing occurs, neglecting evaporation, (b) The mass transfer coefficient, h_m , for the evaporation process, (c) Lowest air temperature, T_∞ , before freezing occurs, including evaporation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Water insulated from ground, (3) Water surface has $\varepsilon = 1$, (4) Heat-mass transfer analogy applies, (5) Ambient air is dry.

PROPERTIES: Table A-4, Air ($T_f \approx 2.5^\circ\text{C} \approx 276\text{K}$, 1 atm): $\rho = 1.2734\text{ kg/m}^3$, $c_p = 1006\text{ J/kg}\cdot\text{K}$, $\alpha = 19.3 \times 10^{-6}\text{ m}^2/\text{s}$; Table A-6, Water vapor (273.15K): $h_{fg} = 2502\text{ kJ/kg}$, $\rho_g = 1/v_g = 4.847 \times 10^{-3}\text{ kg/m}^3$; Table A-8, Water vapor - air (298K): $D_{AB} = 0.26 \times 10^{-4}\text{ m}^2/\text{s}$.

ANALYSIS: (a) Neglecting evaporation and performing an energy balance,

$$q''_{\text{conv}} - q''_{\text{rad}} = 0$$

$$h(T_\infty - T_s) - \varepsilon\sigma(T_s^4 - T_{\text{sky}}^4) = 0 \quad \text{or} \quad T_\infty = T_s + (\varepsilon\sigma/h)(T_s^4 - T_{\text{sky}}^4)$$

$$T_\infty = 0^\circ\text{C} + \frac{1 \times 5.667 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4}{25\text{ W/m}^2 \cdot \text{K}} \left[(0 + 273)^4 - (-30 + 273)^4 \right] = 4.69^\circ\text{C}. \quad <$$

(b) Invoking the heat-mass transfer analogy in the form of Eq. 6.60 with $n = 1/3$,

$$\frac{h}{h_m} = \rho c_p \text{Le}^{2/3} \quad \text{or} \quad h_m = h/\rho c_p \text{Le}^{2/3} \quad \text{where} \quad \text{Le} = \alpha/D_{AB}$$

$$h_m = (25\text{ W/m}^2 \cdot \text{K}) / 1.273\text{ kg/m}^3 (1006\text{ J/kg} \cdot \text{K}) \left[\frac{19.3 \times 10^{-6}\text{ m}^2/\text{s}}{0.26 \times 10^{-4}\text{ m}^2/\text{s}} \right]^{2/3} = 0.0238\text{ m/s}. \quad <$$

(c) Including evaporation effects and performing an energy balance gives $q''_{\text{conv}} - q''_{\text{rad}} - q''_{\text{evap}} = 0$

where $q''_{\text{evap}} = \dot{m}'' h_{fg} = h_m(\rho_{A,s} - \rho_{A,\infty})h_{fg}$, $\rho_{A,s} = \rho_g$ and $\rho_{A,\infty} = 0$. Hence,

$$T_\infty = T_s + (\varepsilon\sigma/h)(T_s^4 - T_{\text{sky}}^4) + (h_m/h)(\rho_g - 0)h_{fg}$$

$$T_\infty = 4.69^\circ\text{C} + \frac{0.0238\text{ m/s}}{25\text{ W/m}^2 \cdot \text{K}} \times 4.847 \times 10^{-3}\text{ kg/m}^3 \times 2.502 \times 10^6\text{ J/kg}$$

$$T_\infty = 4.69^\circ\text{C} + 11.5^\circ\text{C} = 16.2^\circ\text{C}. \quad <$$

PROBLEM 6.66

KNOWN: Wet-bulb and dry-bulb temperature for water vapor-air mixture.

FIND: (a) Partial pressure, p_A , and relative humidity, ϕ , using Carrier's equation, (b) p_A and ϕ using psychrometric chart, (c) Difference between air stream, T_∞ , and wet bulb temperatures based upon evaporative cooling considerations.

SCHEMATIC:

ASSUMPTIONS: (1) Evaporative cooling occurs at interface, (2) Heat-mass transfer analogy applies, (3) Species A and B are perfect gases.

PROPERTIES: Table A-6, Water vapor: $p_{A,\text{sat}}(21.1^\circ\text{C}) = 0.02512 \text{ bar}$, $p_{A,\text{sat}}(37.8^\circ\text{C}) = 0.06603 \text{ bar}$, $h_{fg}(21.1^\circ\text{C}) = 2451 \text{ kJ/kg}$; Table A-4, Air ($T_{\text{am}} = [T_{\text{WB}} + T_{\text{DB}}]/2 \cong 300\text{K}$, 1 atm): $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$, $c_p = 1007 \text{ J/kg}\cdot\text{K}$, $\rho = 1.15 \text{ kg/m}^3$; Table A-8, Air-water vapor (298K): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: (a) Carrier's equation has the form

$$p_v = p_{\text{gw}} - \frac{(p - p_{\text{gw}})(T_{\text{DB}} - T_{\text{WB}})}{1810 - T_{\text{WB}}}$$

where p_v = partial pressure of vapor in air stream, bar

p_{gw} = sat. pressure at $T_{\text{WB}} = 21.1^\circ\text{C}$, 0.02512 bar

p = total pressure of mixture, 1.033 bar

T_{DB} = dry bulb temperature, 37.8°C

T_{WB} = wet bulb temperature, 21.1°C .

Hence,

$$p_v = 0.02512 \text{ bar} - \frac{(1.013 - 0.02512) \text{ bar} \times (37.8 - 21.1)^\circ\text{C}}{1810 - (21.1 + 273.1) \text{ K}} = 0.0142 \text{ bar}.$$

The relative humidity, ϕ , is then

$$\phi \equiv \frac{p_A}{p_{A,\text{sat}}} = \frac{p_v}{p_A(37.8^\circ\text{C})} = \frac{0.0142 \text{ bar}}{0.06603 \text{ bar}} = 0.214. \quad <$$

(b) Using a psychrometric chart

$$\left. \begin{array}{l} T_{\text{WB}} = 21.1^\circ\text{C} = 70^\circ\text{F} \\ T_{\text{DB}} = 37.8^\circ\text{C} = 100^\circ\text{F} \end{array} \right\} \phi \approx 0.225 \quad <$$

$$p_v = \phi p_{\text{sat}} = 0.225 \times 0.06603 \text{ bar} = 0.0149 \text{ bar}. \quad <$$

Continued

PROBLEM 6.66 (Cont.)

(c) An application of the heat-mass transfer analogy is the process of evaporative cooling which occurs when air flows over water. The change in temperature is estimated by Eq. 6.65.

$$T_{\infty} - T_s = \frac{\mathcal{M}_A h_{fg}}{\mathcal{R} \rho c_p L e^{2/3}} \left[\frac{p_{A,\text{sat}}(T_s)}{T_s} - \frac{p_{A,\infty}}{T_{\infty}} \right]$$

or

$$(37.8 - 21.1)\text{K} = \frac{(18\text{kg/kmol} \times 2451 \times 10^3 \text{J/kg})}{8.314 \times 10^{-2} \text{m}^3 \text{bar/kmol} \cdot \text{K} \times 1.16 \text{kg/m}^3 \times 1007 \text{J/kg} \cdot \text{K} \times \left(\frac{22.5 \times 10^{-6} \text{m}^2/\text{s}}{0.26 \times 10^{-4} \text{m}^2/\text{s}} \right)^{2/3}} \times \left[\frac{0.02512 \text{bar}}{(273 + 21.1)\text{K}} + \frac{p_{A,\infty}}{(273 + 37.8)\text{K}} \right]$$

Thus, $p_{A,\infty} = 0.016 \text{ bar}$

and

$$\phi = p_A/p_{A,\text{sat}} = p_v/p_{A,\text{sat}} = 0.016 \text{ bar}/0.06603 \text{ bar} = 0.242 \quad <$$

COMMENTS: The following table compares results from the two calculation methods.

	<i>Carrier's Eq.</i>	<i>Psychrometric Chart</i>
p_v (bar)	0.0142	0.016
ϕ	0.214	0.242

$$\% \text{ Difference: } \frac{0.242 - 0.214}{0.214} \times 100 = 13.1\%.$$

PROBLEM 6.67

KNOWN: Wet and dry bulb temperatures.

FIND: Relative humidity of air.

SCHEMATIC:

ASSUMPTIONS: (1) Perfect gas behavior for vapor, (2) Steady-state conditions, (3) Negligible radiation, (4) Negligible conduction along thermometer.

PROPERTIES: Table A-4, Air (308K, 1 atm): $\rho = 1.135 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg}\cdot\text{K}$, $\alpha = 23.7 \times 10^{-6} \text{ m}^2/\text{s}$; Table A-6, Saturated water vapor (298K): $v_g = 44.25 \text{ m}^3/\text{kg}$, $h_{fg} = 2443 \text{ kJ/kg}$; (318K): $v_g = 15.52 \text{ m}^3/\text{kg}$; Table A-8, Air-vapor (1 atm, 298K): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$, $D_{AB} (308\text{K}) = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \times (308/298)^{3/2} = 0.27 \times 10^{-4} \text{ m}^2/\text{s}$, $Le = \alpha/D_{AB} = 0.88$.

ANALYSIS: From an energy balance on the wick, Eq. 6.64 follows from Eq. 6.61. Dividing Eq. 6.64 by $\rho_{A,\text{sat}}(T_\infty)$,

$$\frac{T_\infty - T_s}{\rho_{A,\text{sat}}(T_\infty)} = h_{fg} \left[\frac{h_m}{h} \right] \left[\frac{\rho_{A,\text{sat}}(T_s)}{\rho_{A,\text{sat}}(T_\infty)} - \frac{\rho_{A,\infty}}{\rho_{A,\text{sat}}(T_\infty)} \right].$$

With $[\rho_{A,\infty} / \rho_{A,\text{sat}}(T_\infty)] \approx \phi_\infty$ for a perfect gas and h/h_m given by Eq. 6.60,

$$\phi_\infty = \frac{\rho_{A,\text{sat}}(T_s)}{\rho_{A,\text{sat}}(T_\infty)} - \frac{\rho c_p Le^{2/3}}{\rho_{A,\text{sat}}(T_\infty) h_{fg}} (T_\infty - T_s).$$

Using the property values, evaluate

$$\begin{aligned} \frac{\rho_{A,\text{sat}}(T_s)}{\rho_{A,\text{sat}}(T_\infty)} &= \frac{v_g T_\infty}{v_g(T_s)} = \frac{15.52}{44.25} = 0.351 \\ \rho_{A,\text{sat}}(T_\infty) &= (15.52 \text{ m}^3/\text{kg})^{-1} = 0.064 \text{ kg/m}^3. \end{aligned}$$

Hence,

$$\phi_\infty = 0.351 - \frac{1.135 \text{ kg/m}^3 (1007 \text{ J/kg}\cdot\text{K})(0.88)^{2/3}}{0.064 \text{ kg/m}^3 (2.443 \times 10^6 \text{ J/kg})} (45 - 25) \text{ K}$$

$$\phi_\infty = 0.351 - 0.133 = 0.218.$$

<

COMMENTS: Note that latent heat must be evaluated at the surface temperature (evaporation occurs at the surface).

PROBLEM 6.68

KNOWN: Heat transfer correlation for a contoured surface heated from below while experiencing air flow across it. Flow conditions and steady-state temperature when surface experiences evaporation from a thin water film.

FIND: (a) Heat transfer coefficient and convection heat rate, (b) Mass transfer coefficient and evaporation rate (kg/h) of the water, (c) Rate at which heat must be supplied to surface for these conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applies, (3) Correlation requires properties evaluated at $T_f = (T_s + T_\infty)/2$.

PROPERTIES: Table A-4, Air ($T_f = (T_s + T_\infty)/2 = (290 + 310)\text{K}/2 = 300\text{K}$, 1 atm): $\nu = 15.89 \times 10^{-6}\text{m}^2/\text{s}$, $k = 0.0263\text{W/m}\cdot\text{K}$, $Pr = 0.707$; Table A-8, Air-water mixture (300 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}\text{m}^2/\text{s}$; Table A-6, Sat. water ($T_s = 310\text{K}$): $\rho_{A,\text{sat}} = 1/v_g = 1/22.93\text{m}^3/\text{kg} = 0.04361\text{kg/m}^3$, $h_{fg} = 2414\text{kJ/kg}$.

ANALYSIS: (a) To characterize the flow, evaluate Re_L at T_f

$$Re_L = \frac{VL}{\nu} = \frac{10\text{ m/s} \times 1\text{ m}}{15.89 \times 10^{-6}\text{ m}^2/\text{s}} = 6.293 \times 10^5$$

and substituting into the prescribed correlation for this surface, find

$$\bar{Nu}_L = 0.43 \left(6.293 \times 10^5 \right)^{0.58} (0.707)^{0.4} = 864.1$$

$$\bar{h}_L = \frac{\bar{Nu}_L \cdot k}{L} = \frac{864.1 \times 0.0263\text{ W/m}\cdot\text{K}}{1\text{ m}} = 22.7\text{ W/m}^2 \cdot \text{K}. \quad <$$

Hence, the convection heat rate is

$$q_{\text{conv}} = \bar{h}_L A_s (T_s - T_\infty)$$

$$q_{\text{conv}} = 22.7\text{ W/m}^2 \cdot \text{K} \times 1\text{ m}^2 (310 - 290)\text{K} = 454\text{ W} \quad <$$

(b) Invoking the heat-mass transfer analogy

$$\bar{Sh}_L = \frac{\bar{h}_m L}{D_{AB}} = 0.43 Re_L^{0.58} Sc^{0.4}$$

where

$$Sc = \frac{\nu}{D_{AB}} = \frac{15.89 \times 10^{-6}\text{ m}^2/\text{s}}{0.26 \times 10^{-4}\text{ m}^2/\text{s}} = 0.611$$

and ν is evaluated at T_f . Substituting numerical values, find

Continued

PROBLEM 6.68 (Cont.)

$$\overline{Sh}_L = 0.43 \left(6.293 \times 10^5 \right)^{0.58} (0.611)^{0.4} = 815.2$$

$$\bar{h}_m = \frac{\overline{Sh}_L \cdot D_{AB}}{L} = \frac{815.2 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s}}{1 \text{ m}} = 2.12 \times 10^{-2} \text{ m/s.}$$

<

The evaporation rate, with $\rho_{A,s} = \rho_{A,\text{sat}}(T_s)$, is

$$\begin{aligned} \dot{m} &= \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) \\ \dot{m} &= 2.12 \times 10^{-2} \text{ m/s} \times 1 \text{ m}^2 (0.04361 - 0) \text{ kg/m}^3 \end{aligned}$$

$$\dot{m} = 9.243 \times 10^{-4} \text{ kg/s} = 3.32 \text{ kg/h.}$$

<

(c) The rate at which heat must be supplied to the plate to maintain these conditions follows from an energy balance.

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= 0 \\ q_{\text{in}} - q_{\text{conv}} - q_{\text{evap}} &= 0 \end{aligned}$$

where q_{in} is the heat supplied to sustain the losses by convection and evaporation.

$$\begin{aligned} q_{\text{in}} &= q_{\text{conv}} + q_{\text{evap}} \\ q_{\text{in}} &= \bar{h}_L A_s (T_s - T_{\infty}) + \dot{m} h_{fg} \\ q_{\text{in}} &= 454 \text{ W} + 9.243 \times 10^{-4} \text{ kg/s} \times 2414 \times 10^3 \text{ J/kg} \end{aligned}$$

$$q_{\text{in}} = (254 + 2231) \text{ W} = 2685 \text{ W.}$$

<

COMMENTS: Note that the loss from the surface by evaporation is nearly 5 times that due to convection.

PROBLEM 6.69

KNOWN: Thickness, temperature and evaporative flux of a water layer. Temperature of air flow and surroundings.

FIND: (a) Convection mass transfer coefficient and time to completely evaporate the water, (b) Convection heat transfer coefficient, (c) Heater power requirement per surface area, (d) Temperature of dry surface if heater power is maintained.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Applicability of heat and mass transfer analogy with $n = 1/3$, (3) Radiation exchange at surface of water may be approximated as exchange between a small surface and large surroundings, (4) Air is dry ($\rho_{A,\infty} = 0$), (5) Negligible heat transfer from unwetted surface of the plate.

PROPERTIES: Table A-6, Water ($T_w = 340\text{K}$): $\rho_f = 979\text{ kg/m}^3$, $\rho_{A,\text{sat}} = v_g^{-1} = 0.174\text{ kg/m}^3$, $h_{fg} = 2342\text{ kJ/kg}$. Prescribed, Air: $\rho = 1.08\text{ kg/m}^3$, $c_p = 1008\text{ J/kg}\cdot\text{K}$, $k = 0.028\text{ W/m}\cdot\text{K}$. Vapor/Air: $D_{AB} = 0.29 \times 10^{-4}\text{ m}^2/\text{s}$. Water: $\epsilon_w = 0.95$. Plate: $\epsilon_p = 0.60$.

ANALYSIS: (a) The convection mass transfer coefficient may be determined from the rate equation $n''_A = h_m(\rho_{A,s} - \rho_{A,\infty})$, where $\rho_{A,s} = \rho_{A,\text{sat}}(T_w)$ and $\rho_{A,\infty} = 0$. Hence,

$$h_m = \frac{n''_A}{\rho_{A,\text{sat}}} = \frac{0.03\text{ kg/s}\cdot\text{m}^2}{0.174\text{ kg/m}^3} = 0.172\text{ m/s} \quad <$$

The time required to completely evaporate the water is obtained from a mass balance of the form $-n''_A = \rho_f d\delta/dt$, in which case

$$\rho_f \int_{\delta_i}^0 d\delta = -n''_A \int_0^t dt$$

$$t = \frac{\rho_f \delta_i}{n''_A} = \frac{979\text{ kg/m}^3 (0.002\text{ m})}{0.03\text{ kg/s}\cdot\text{m}^2} = 65.3\text{ s} \quad <$$

(b) With $n = 1/3$ and $Le = \alpha/D_{AB} = k/\rho c_p D_{AB} = 0.028\text{ W/m}\cdot\text{K}/(1.08\text{ kg/m}^3 \times 1008\text{ J/kg}\cdot\text{K} \times 0.29 \times 10^{-4}\text{ m}^2/\text{s}) = 0.887$, the heat and mass transfer analogy yields

$$h = \frac{k h_m}{D_{AB} Le^{1/3}} = \frac{0.028\text{ W/m}\cdot\text{K} (0.172\text{ m/s})}{0.29 \times 10^{-4}\text{ m}^2/\text{s} (0.887)^{1/3}} = 173\text{ W/m}^2\cdot\text{K} \quad <$$

The electrical power requirement per unit area corresponds to the rate of heat loss from the water. Hence,

Continued

PROBLEM 6.69 (Cont.)

$$P''_{\text{elec}} = q''_{\text{evap}} + q''_{\text{conv}} + q''_{\text{rad}} = n''_A h_{fg} + h(T_w - T_\infty) + \varepsilon_w \sigma (T_w^4 - T_{\text{sur}}^4)$$

$$P''_{\text{elec}} = 0.03 \text{ kg/s} \cdot \text{m}^2 \left(2.342 \times 10^6 \text{ J/kg} \right) + 173 \text{ W/m}^2 \cdot \text{K} (40\text{K}) + 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (340^4 - 300^4)$$

$$P''_{\text{elec}} = 70,260 \text{ W/m}^2 + 6920 \text{ W/m}^2 + 284 \text{ W/m}^2 = 77,464 \text{ W/m}^2 \quad <$$

(c) After complete evaporation, the steady-state temperature of the plate is determined from the requirement that

$$P''_{\text{elec}} = h(T_p - T_\infty) + \varepsilon_p \sigma (T_p^4 - T_{\text{sur}}^4)$$

$$77,464 \text{ W/m}^2 = 173 \text{ W/m}^2 \cdot \text{K} (T_p - 300) + 0.60 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_p^4 - 300^4)$$

$$T_p = 702\text{K} = 429^\circ\text{C} \quad <$$

COMMENTS: The evaporative heat flux is the dominant contributor to heat transfer from the water layer, with convection of sensible energy being an order of magnitude smaller and radiation exchange being negligible. Without evaporation (a dry surface), convection dominates and is approximately an order of magnitude larger than radiation.

PROBLEM 6.70

KNOWN: Heater power required to maintain water film at prescribed temperature in dry ambient air and evaporation rate.

FIND: (a) Average mass transfer convection coefficient \bar{h}_m , (b) Average heat transfer convection coefficient \bar{h} , (c) Whether values of \bar{h}_m and \bar{h} satisfy the heat-mass analogy, and (d) Effect on evaporation rate and disc temperature if relative humidity of the ambient air were increased from 0 to 0.5 but with heater power maintained at the same value.

SCHEMATIC:

ASSUMPTIONS: (1) Water film and disc are at same temperature; (2) Mass and heat transfer coefficient are independent of ambient air relative humidity, (3) Constant properties.

PROPERTIES: Table A-6, Saturated water (305 K): $v_g = 29.74 \text{ m}^3/\text{kg}$, $h_{fg} = 2426 \times 10^3 \text{ J/kg}$; Table A-4, Air ($\bar{T} = 300 \text{ K}$, 1 atm): $k = 0.0263 \text{ W/m}\cdot\text{K}$, $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$, Table A-8, Air-water vapor (300 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: (a) Using the mass transfer convection rate equation,

$$n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) = \bar{h}_m A_s \rho_{A,\text{sat}} (1 - \phi_\infty)$$

and evaluating $\rho_{A,s} = \rho_{A,\text{sat}}(305 \text{ K}) = 1/v_g(305 \text{ K})$ with $\phi_\infty \sim \rho_{A,\infty} = 0$, find

$$\bar{h}_m = \frac{n_A}{A_s (\rho_{A,s} - \rho_{A,\infty})}$$

$$\bar{h}_m = \frac{2.55 \times 10^{-4} \text{ kg/hr} / (3600 \text{ s/hr})}{\left(\pi (0.020 \text{ m})^2 / 4 \right) (1/29.74 - 0) \text{ kg/m}^3} = 6.71 \times 10^{-3} \text{ m/s.} \quad <$$

(b) Perform an overall energy balance on the disc,

$$q = q_{\text{conv}} + q_{\text{evap}} = \bar{h} A_s (T_s - T_\infty) + n_A h_{fg}$$

and substituting numerical values with h_{fg} evaluated at T_s , find \bar{h} :

$$200 \times 10^{-3} \text{ W} = \bar{h} \pi (0.020 \text{ m})^2 / 4 (305 - 295) \text{ K} + 7.083 \times 10^{-8} \text{ kg/s} \times 2426 \times 10^3 \text{ J/kg}$$

$$\bar{h} = 8.97 \text{ W/m}^2 \cdot \text{K.} \quad <$$

Continued

PROBLEM 6.70 (Cont.)

(c) The heat-mass transfer analogy, Eq. 6.67, requires that

$$\frac{\bar{h}}{h_m} \stackrel{?}{=} \frac{k}{D_{AB}} \left(\frac{D_{AB}}{\alpha} \right)^{1/3}.$$

Evaluating k and D_{AB} at $\bar{T} = (T_s + T_\infty)/2 = 300 \text{ K}$ and substituting numerical values,

$$\frac{8.97 \text{ W/m}^2 \cdot \text{K}}{6.71 \times 10^{-3} \text{ m/s}} = 1337 \neq \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.26 \times 10^{-4} \text{ m}^2/\text{s}} \left(\frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{22.5 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{1/3} = 1061$$

Since the equality is not satisfied, we conclude that, for this situation, the analogy is only approximately met ($\approx 30\%$).

(d) If $\phi_\infty = 0.5$ instead of 0.0 and q is unchanged, n_A will decrease by nearly a factor of two, as will $n_A h_{fg} = q_{\text{evap}}$. Hence, since q_{conv} must increase and \bar{h} remains nearly constant, $T_s - T_\infty$ must increase. Hence, T_s will increase.

COMMENTS: Note that in part (d), with an increase in T_s , h_{fg} decreases, but only slightly, and $\rho_{A,\text{sat}}$ increases. From a trial-and-error solution assuming constant values for \bar{h}_m and h , the disc temperature is 315 K for $\phi_\infty = 0.5$.

PROBLEM 6.71

KNOWN: Power-time history required to completely evaporate a droplet of fixed diameter maintained at 37°C.

FIND: (a) Average mass transfer convection coefficient when droplet, heater and dry ambient air are at 37°C and (b) Energy required to evaporate droplet if the dry ambient air temperature is 27°C.

SCHEMATIC:

ASSUMPTIONS: (1) Wetted surface area of droplet is of fixed diameter D , (2) Heat-mass transfer analogy is applicable, (3) Heater controlled to operate at constant temperature, $T_s = 37^\circ\text{C}$, (4) Mass of droplet same for part (a) and (b), (5) Mass transfer coefficients for parts (a) and (b) are the same.

PROPERTIES: Table A-6, Saturated water ($37^\circ\text{C} = 310 \text{ K}$): $h_{fg} = 2414 \text{ kJ/kg}$, $\rho_{A,\text{sat}} = 1/v_g = 1/22.93 = 0.04361 \text{ kg/m}^3$; Table A-8, Air-water vapor ($T_s = 37^\circ\text{C} = 310 \text{ K}$, 1 atm): $D_{AB} = 0.26 \times 10^{-6} \text{ m}^2/\text{s} (310/298)^{3/2} = 0.276 \times 10^{-6} \text{ m}^2/\text{s}$; Table A-4, Air ($\bar{T} = (27 + 37)^\circ\text{C}/2 = 305 \text{ K}$, 1 atm): $\rho = 1.1448 \text{ kg/m}^3$, $c_p = 1008 \text{ J/kg}\cdot\text{K}$, $\nu = 16.39 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 0.706$.

ANALYSIS: (a) For the isothermal conditions (37°C), the electrical energy Q required to evaporate the droplet during the interval of time $\Delta t = t_e$ follows from the area under the P - t curve above,

$$Q = \int_0^{t_e} P dt = \left[20 \times 10^{-3} \text{ W} \times (50 \times 60) \text{ s} + 0.5 \times 20 \times 10^{-3} \text{ W} (100 - 50) \times 60 \text{ s} \right]$$

$$Q = 90 \text{ J}.$$

From an overall energy balance during the interval of time $\Delta t = t_e$, the mass loss due to evaporation is

$$Q = M h_{fg} \quad \text{or} \quad M = Q/h_{fg}$$

$$M = 90 \text{ J} / 2414 \times 10^3 \text{ J/kg} = 3.728 \times 10^{-5} \text{ kg}.$$

To obtain the average mass transfer coefficient, write the rate equation for an interval of time $\Delta t = t_e$,

$$M = \dot{m} \cdot t_e = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) \cdot t_e = \bar{h}_m A_s \rho_{A,s} (1 - \phi_\infty) \cdot t_e$$

Substituting numerical values with $\phi_\infty = 0$, find

$$3.728 \times 10^{-5} \text{ kg} = \bar{h}_m \left(\pi (0.004 \text{ m})^2 / 4 \right) 0.04361 \text{ kg/m}^3 \times (100 \times 60) \text{ s}$$

Continued

PROBLEM 6.71 (Cont.)

$$\bar{h}_m = 0.0113 \text{ m/s.}$$

<

(b) The energy required to evaporate the droplet of mass $M = 3.728 \times 10^{-5} \text{ kg}$ follows from an overall energy balance,

$$Q = Mh_{fg} + \bar{h}A_s(T_s - T_\infty)$$

where \bar{h} is obtained from the heat-mass transfer analogy, Eq. 6.60, using $n = 1/3$,

$$\frac{\bar{h}}{h_m} = \frac{k}{D_{AB}Le^n} = \rho c_p Le^{2/3}$$

where

$$Sc = \frac{\nu}{D_{AB}} = \frac{16.39 \times 10^{-6} \text{ m}^2/\text{s}}{0.276 \times 10^{-4} \text{ m}^2/\text{s}} = 0.594$$
$$Le = \frac{Sc}{Pr} = \frac{0.594}{0.706} = 0.841.$$

Hence,

$$\bar{h} = 0.0113 \text{ m/s} \times 1.1448 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} (0.841)^{2/3} = 11.62 \text{ W/m}^2 \cdot \text{K}.$$

and the energy requirement is

$$Q = 3.728 \times 10^{-5} \text{ kg} \times 2414 \text{ kJ/kg} + 11.62 \text{ W/m}^2 \cdot \text{K} \left(\pi (0.004 \text{ m})^2 / 4 \right) (37 - 27)^\circ \text{C}$$

$$Q = (90.00 + 0.00145) \text{ J} = 90 \text{ J.}$$

<

The energy required to meet the convection heat loss is very small compared to that required to sustain the evaporative loss.

PROBLEM 6.72

KNOWN: Initial plate temperature $T_p(0)$ and saturated air temperature (T_∞) in a dishwasher at the start of the dry cycle. Thermal mass per unit area of the plate $Mc/A_s = 1600 \text{ J/m}^2 \cdot \text{K}$.

FIND: (a) Differential equation to predict plate temperature as a function of time during the dry cycle and (b) Rate of change in plate temperature at the start of the dry cycle assuming the average convection heat transfer coefficient is $3.5 \text{ W/m}^2 \cdot \text{K}$.

SCHEMATIC:

ASSUMPTIONS: (1) Plate is spacewise isothermal, (2) Negligible thermal resistance of water film on plate, (3) Heat-mass transfer analogy applies.

PROPERTIES: Table A-4, Air ($\bar{T} = (55 + 65)^\circ\text{C}/2 = 333 \text{ K}$, 1 atm): $\rho = 1.0516 \text{ kg/m}^3$, $c_p = 1008 \text{ J/kg} \cdot \text{K}$, $\text{Pr} = 0.703$, $\nu = 19.24 \times 10^{-6} \text{ m}^2/\text{s}$; Table A-6, Saturated water vapor, ($T_s = 65^\circ\text{C} = 338 \text{ K}$): $\rho_A = 1/\nu_g = 0.1592 \text{ kg/m}^3$, $h_{fg} = 2347 \text{ kJ/kg}$; ($T_s = 55^\circ\text{C} = 328 \text{ K}$): $\rho_{A,\infty} = 1/\nu_g = 0.1029 \text{ kg/m}^3$; Table A-8, Air-water vapor ($T_s = 65^\circ\text{C} = 338 \text{ K}$, 1 atm): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ ($338/298$) $^{3/2} = 0.314 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: (a) Perform an energy balance on a rate basis on the plate,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}} \quad q''_{\text{conv}} - q''_{\text{evap}} = (Mc/A_s)(dT_p/dt).$$

Using the rate equations for the heat and mass transfer fluxes, find

$$\bar{h}[T_\infty - T_p(t)] - \bar{h}_m[\rho_{A,s}(T_s) - \rho_{A,\infty}(T_\infty)]h_{fg} = (Mc/A_s)(dT/dt). \quad <$$

(b) To evaluate the change in plate temperature at $t = 0$, the start of the drying process when $T_p(0) = 65^\circ\text{C}$ and $T_\infty = 55^\circ\text{C}$, evaluate \bar{h}_m from knowledge of $\bar{h} = 3.5 \text{ W/m}^2 \cdot \text{K}$ using the heat-mass transfer analogy, Eq. 6.60, with $n = 1/3$,

$$\frac{\bar{h}}{\bar{h}_m} = \rho c_p \text{Le}^{2/3} = \rho c_p \left(\frac{\text{Sc}}{\text{Pr}} \right)^{2/3} = \rho c_p \left(\frac{\nu/D_{AB}}{\text{Pr}} \right)^{2/3}$$

and evaluating thermophysical properties at their appropriate temperatures, find

$$\frac{3.5 \text{ W/m}^2 \cdot \text{K}}{\bar{h}_m} = 1.0516 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} \left(\frac{19.24 \times 10^{-6} \text{ m}^2/\text{s}}{0.703} \right)^{2/3} \quad \bar{h}_m = 3.619 \times 10^{-3} \text{ m/s}.$$

Substituting numerical values into the conservation expression of part (a), find

$$3.5 \text{ W/m}^2 \cdot \text{K} (55 - 65)^\circ\text{C} - 3.619 \times 10^{-3} \text{ m/s} (0.1592 - 0.1029) \text{ kg/m}^3 \times 2347 \times 10^3 \text{ J/kg} = 1600 \text{ J/m}^2 \cdot \text{K} (dT_p/dt)$$

$$dT_p/dt = -[35.0 + 478.2] \text{ W/m}^2 \cdot \text{K} / 1600 \text{ J/m}^2 \cdot \text{K} = -0.32 \text{ K/s}. \quad <$$

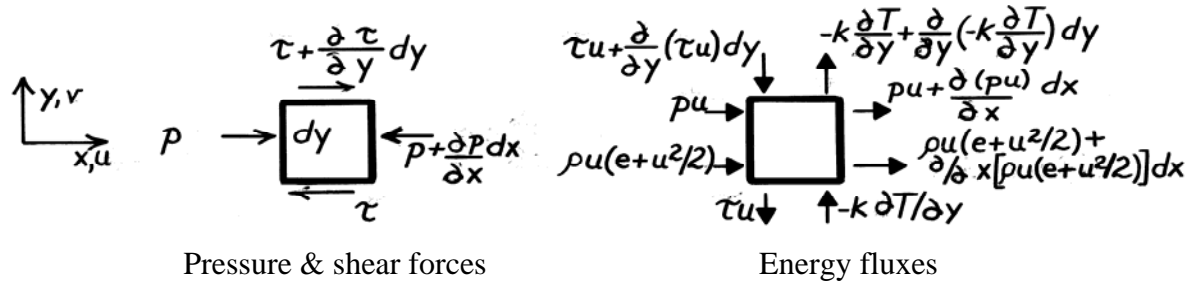

COMMENTS: This rate of temperature change will not be sustained for long, since, as the plate cools, the rate of evaporation (which dominates the cooling process) will diminish.

PROBLEM 6S.1

KNOWN: Two-dimensional flow conditions for which $v = 0$ and $T = T(y)$.

FIND: (a) Verify that $u = u(y)$, (b) Derive the x-momentum equation, (c) Derive the energy equation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Negligible body forces, (4) $v = 0$, (5) $T = T(y)$ or $\partial T / \partial x = 0$, (6) Thermal energy generation occurs only by viscous dissipation.

ANALYSIS: (a) From the mass continuity equation, it follows from the prescribed conditions that $\partial u / \partial x = 0$. Hence $u = u(y)$.

(b) From Newton's second law of motion, $\Sigma F_x = (\text{Rate of increase of fluid momentum})_x$,

$$\left[p - \left[p + \frac{\partial p}{\partial x} dx \right] \right] dy \cdot 1 + \left[-\tau + \left[\tau + \frac{\partial \tau}{\partial y} dy \right] \right] dx \cdot 1 = \left\{ (\rho u)u + \frac{\partial}{\partial x} [(\rho u)u] dx \right\} dy \cdot 1 - (\rho u)u dy \cdot 1$$

Hence, with $\tau = \mu (\partial u / \partial y)$, it follows that

$$-\frac{\partial p}{\partial x} + \frac{\partial \tau}{\partial y} = \frac{\partial}{\partial x} [(\rho u)u] = 0 \quad \frac{\partial p}{\partial x} = \mu \frac{\partial^2 u}{\partial y^2}. \quad <$$

(c) From the conservation of energy requirement and the prescribed conditions, it follows that $\dot{E}_{in} - \dot{E}_{out} = 0$, or

$$\begin{aligned} & \left[pu + \rho u \left(e + u^2 / 2 \right) \right] dy \cdot 1 + \left[-k \frac{\partial T}{\partial y} + \tau u + \frac{\partial (\tau u)}{\partial y} dy \right] dx \cdot 1 \\ & - \left\{ pu + \frac{\partial}{\partial x} (pu) dx + \rho u \left(e + u^2 / 2 \right) + \frac{\partial}{\partial x} \left[\rho u \left(e + u^2 / 2 \right) \right] dx \right\} dy \cdot 1 - \left[\tau u - k \frac{\partial T}{\partial y} + \frac{\partial}{\partial y} \left[-k \frac{\partial T}{\partial y} \right] dy \right] dx \cdot 1 = 0 \end{aligned}$$

or,

$$\frac{\partial (\tau u)}{\partial y} - \frac{\partial}{\partial x} (pu) - \frac{\partial}{\partial x} \left[\rho u \left(e + u^2 / 2 \right) \right] + \frac{\partial}{\partial y} \left[k \frac{\partial T}{\partial y} \right] = 0$$

$$\tau \frac{\partial u}{\partial y} + u \frac{\partial \tau}{\partial y} - u \frac{\partial p}{\partial x} + k \frac{\partial^2 T}{\partial y^2} = 0.$$

Noting that the second and third terms cancel from the momentum equation,

$$\mu \left[\frac{\partial u}{\partial y} \right]^2 + k \left[\frac{\partial^2 T}{\partial y^2} \right] = 0. \quad <$$

PROBLEM 6S.10

KNOWN: Steady, incompressible, laminar flow between infinite parallel plates at different temperatures.

FIND: (a) Form of continuity equation, (b) Form of momentum equations and velocity profile. Relationship of pressure gradient to maximum velocity, (c) Form of energy equation and temperature distribution. Heat flux at top surface.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional flow (no variations in z) between infinite, parallel plates, (2) Negligible body forces, (3) No internal energy generation, (4) Incompressible fluid with constant properties.

ANALYSIS: (a) For two-dimensional, steady conditions, the continuity equation is

$$\frac{\partial(\rho u)}{\partial x} + \frac{\partial(\rho v)}{\partial y} = 0.$$

Hence, for an incompressible fluid (constant ρ) in parallel flow ($v = 0$),

$$\frac{\partial u}{\partial x} = 0.$$

<

The flow is fully developed in the sense that, irrespective of y , u is independent of x .

(b) With the above result and the prescribed conditions, the momentum equations reduce to

$$0 = -\frac{\partial p}{\partial x} + \mu \frac{\partial^2 u}{\partial y^2} \quad 0 = -\frac{\partial p}{\partial y}$$

<

Since p is independent of y , $\partial p / \partial x = dp/dx$ is independent of y and

$$\mu \frac{\partial^2 u}{\partial y^2} = \mu \frac{d^2 u}{dy^2} = \frac{dp}{dx}.$$

Since the left-hand side can, at most, depend only on y and the right-hand side is independent of y , both sides must equal the same constant C . That is,

$$\mu \frac{d^2 u}{dy^2} = C.$$

Hence, the velocity distribution has the form

$$u(y) = \frac{C}{2\mu} y^2 + C_1 y + C_2.$$

Using the boundary conditions to evaluate the constants,

$$u(0) = 0 \rightarrow C_2 = 0 \quad \text{and} \quad u(L) = 0 \rightarrow C_1 = -CL/2\mu.$$

Continued

PROBLEM 6S.10 (Cont.)

The velocity profile is $u(y) = \frac{C}{2\mu}(y^2 - Ly)$.

The profile is symmetric about the midplane, in which case the maximum velocity exists at $y = L/2$. Hence,

$$u(L/2) = u_{\max} = \frac{C}{2\mu} \left[-\frac{L^2}{4} \right] \quad \text{or} \quad u_{\max} = -\frac{L^2}{8\mu} \frac{dp}{dx}. \quad <$$

(c) For fully developed thermal conditions, $(\partial T / \partial x) = 0$ and temperature depends only on y . Hence with $v = 0$, $\partial u / \partial x = 0$, and the prescribed assumptions, the energy equation becomes

$$\rho u \frac{\partial i}{\partial x} = k \frac{d^2 T}{dy^2} + u \frac{dp}{dx} + \mu \left[\frac{du}{dy} \right]^2.$$

With $i = e + p/\rho$, $\frac{\partial i}{\partial x} = \frac{\partial e}{\partial x} + \frac{1}{\rho} \frac{dp}{dx}$ where $\frac{\partial e}{\partial x} = \frac{\partial e}{\partial T} \frac{\partial T}{\partial x} + \frac{\partial e}{\partial \rho} \frac{\partial \rho}{\partial x} = 0$.

Hence, the energy equation becomes $0 = k \frac{d^2 T}{dy^2} + \mu \left[\frac{du}{dy} \right]^2.$ <

With $du/dy = (C/2\mu)(2y - L)$, it follows that

$$\frac{d^2 T}{dy^2} = -\frac{C^2}{4k\mu} (4y^2 - 4Ly + L^2).$$

Integrating twice,

$$T(y) = -\frac{C^2}{4k\mu} \left[\frac{y^4}{3} - \frac{2Ly^3}{3} + \frac{L^2 y^2}{2} \right] + C_3 y + C_4$$

Using the boundary conditions to evaluate the constants,

$$T(0) = T_2 \rightarrow C_4 = T_2 \quad \text{and} \quad T(L) = T_1 \rightarrow C_3 = \frac{C^2 L^3}{24k\mu} + \frac{(T_1 - T_2)}{L}.$$

Hence, $T(y) = T_2 + \left[\frac{y}{L} \right] (T_1 - T_2) - \frac{C^2}{4k\mu} \left[\frac{y^4}{3} - \frac{2Ly^3}{3} + \frac{L^2 y^2}{2} - \frac{L^3 y}{6} \right].$ <

From Fourier's law,

$$q''(L) = -k \left. \frac{\partial T}{\partial y} \right|_{y=L} = \frac{k}{L} (T_2 - T_1) + \frac{C^2}{4\mu} \left[\frac{4}{3} L^3 - 2L^3 + L^3 - \frac{L^3}{6} \right]$$

$$q''(L) = \frac{k}{L} (T_2 - T_1) + \frac{C^2 L^3}{24\mu}. \quad <$$

COMMENTS: The third and second terms on the right-hand sides of the temperature distribution and heat flux, respectively, represents the effects of viscous dissipation. If C is large (due to large μ or u_{\max}), viscous dissipation is significant. If C is small, conduction effects dominate.

PROBLEM 6S.11

KNOWN: Steady, incompressible flow of binary mixture between infinite parallel plates with different species concentrations.

FIND: Form of species continuity equation and concentration distribution. Species flux at upper surface.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional flow, (2) No chemical reactions, (3) Constant properties.

ANALYSIS: For fully developed conditions, $\partial C_A / \partial x = 0$. Hence with $v = 0$, the species conservation equation reduces to

$$\frac{d^2 C_A}{dy^2} = 0. \quad <$$

Integrating twice, the general form of the species concentration distribution is

$$C_A(y) = C_1 y + C_2.$$

Using appropriate boundary conditions and evaluating the constants,

$$\begin{aligned} C_A(0) &= C_{A,2} \quad \rightarrow \quad C_2 = C_{A,2} \\ C_A(L) &= C_{A,1} \quad \rightarrow \quad C_1 = (C_{A,1} - C_{A,2})/L, \end{aligned}$$

the concentration distribution is

$$C_A(y) = C_{A,2} + (y/L) (C_{A,1} - C_{A,2}). \quad <$$

From Fick's law, the species flux is

$$\begin{aligned} N_A''(L) &= -D_{AB} \left. \frac{dC_A}{dy} \right|_{y=L} \\ N_A''(L) &= \frac{D_{AB}}{L} (C_{A,2} - C_{A,1}). \quad < \end{aligned}$$

COMMENTS: An analogy between heat and mass transfer exists if viscous dissipation is negligible. The energy equation is then $d^2 T / dy^2 = 0$. Hence, both heat and species transfer are influenced only by diffusion. Expressions for $T(y)$ and $q''(L)$ are analogous to those for $C_A(y)$ and $N_A''(L)$.

PROBLEM 6S.12

KNOWN: Flow conditions between two parallel plates, across which vapor transfer occurs.

FIND: (a) Variation of vapor molar concentration between the plates and mass rate of water production per unit area, (b) Heat required to sustain the process.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed, incompressible flow with constant properties, (3) Negligible body forces, (4) No chemical reactions, (5) All work interactions, including viscous dissipation, are negligible.

ANALYSIS: (a) The flow will be fully developed in terms of the vapor concentration field, as well as the velocity and temperature fields. Hence

$$\frac{\partial C_A}{\partial x} = 0 \quad \text{or} \quad C_A(x, y) = C_A(y).$$

Also, with $\partial C_A / \partial t = 0$, $\dot{N}_A = 0$, $v = 0$ and constant D_{AB} , the species conservation equation reduces to

$$\frac{d^2 C_A}{dy^2} = 0.$$

Separating and integrating twice,

$$C_A(y) = C_1(y) + C_2.$$

Applying the boundary conditions,

$$C_A(0) = C_{A,0} \quad \rightarrow \quad C_2 = C_{A,0}$$

$$C_A(L) = C_{A,L} \quad \rightarrow \quad C_{A,L} = C_1 L + C_2 \quad C_1 = -\frac{C_{A,0} - C_{A,L}}{L}$$

find the species concentration distribution,

$$C_A(y) = C_{A,0} - (C_{A,0} - C_{A,L}) (y/L). \quad <$$

From Fick's law, Eq. 6.7, the species transfer rate is

$$N_A'' = N_{A,s}'' = -D_{AB} \left. \frac{\partial C_A}{\partial y} \right]_{y=0} = D_{AB} \frac{C_{A,0} - C_{A,L}}{L}.$$

Continued

PROBLEM 6S.12 (Cont.)

Multiplying by the molecular weight of water vapor, \mathcal{M}_A , the mass rate of water production per unit area is

$$\dot{n}_A'' = \mathcal{M}_A N_A'' = \mathcal{M}_A D_{AB} \frac{C_{A,0} - C_{A,L}}{L}. \quad <$$

(b) Heat must be supplied to the bottom surface in an amount equal to the latent and sensible heat transfer from the surface,

$$\begin{aligned} q'' &= q''_{\text{lat}} + q''_{\text{sen}} \\ q'' &= n_{A,s}'' h_{fg} + \left[-k \frac{dT}{dy} \right]_{y=0}. \end{aligned}$$

The temperature distribution may be obtained by solving the energy equation, which, for the prescribed conditions, reduces to

$$\frac{d^2 T}{dy^2} = 0.$$

Separating and integrating twice,

$$T(y) = C_1 y + C_2.$$

Applying the boundary conditions,

$$\begin{aligned} T(0) &= T_0 & \rightarrow & C_2 = T_0 \\ T(L) &= T_L & \rightarrow & C_1 = (T_L - T_0)/L \end{aligned}$$

find the temperature distribution,

$$T(y) = T_0 - (T_0 - T_L) y/L.$$

Hence,

$$\left[-k \frac{dT}{dy} \right]_{y=0} = k \frac{(T_0 - T_L)}{L}.$$

Accordingly,

$$q'' = \mathcal{M}_A D_{AB} \frac{C_{A,0} - C_{A,L}}{L} h_{fg} + k \frac{(T_0 - T_L)}{L}. \quad <$$

COMMENTS: Despite the existence of the flow, species and energy transfer across the air are uninfluenced by advection and transfer is only by diffusion. If the flow were not fully developed, advection would have a significant influence on the species concentration and temperature fields and hence on the rate of species and energy transfer. The foregoing results would, of course, apply in the case of no air flow. The physical condition is an example of Poiseuille flow with heat and mass transfer.

PROBLEM 6S.13

KNOWN: The conservation equations, Eqs. 6S.24 and 6S.31.

FIND: (a) Describe physical significance of terms in these equations, (b) Identify approximations and special conditions used to reduce these equations to the boundary layer equations, Eqs. 6.29 and 6.30, (c) Identify the conditions under which these two boundary layer equations have the same form and, hence, an analogy will exist.

ANALYSIS: (a) The energy conservation equation, Eq. 6S.24, has the form

$$\underbrace{\rho u \frac{\partial i}{\partial x}}_{1a} + \underbrace{\rho v \frac{\partial i}{\partial y}}_{1b} = \underbrace{\frac{\partial}{\partial x} \left[k \frac{\partial T}{\partial x} \right]}_{2a} + \underbrace{\frac{\partial}{\partial y} \left[k \frac{\partial T}{\partial y} \right]}_{2b} + \underbrace{\left[u \frac{\partial p}{\partial x} + v \frac{\partial p}{\partial y} \right]}_3 + \underbrace{\mu \Phi}_{4} + \underbrace{\dot{q}}_5$$

The terms, as identified, have the following physical significance:

1. Change of enthalpy (thermal + flow work) advected in x and y directions, <
2. Change of conduction flux in x and y directions,
3. Work done by static pressure forces,
4. Work done by viscous stresses,
5. Rate of energy generation.

The species mass conservation equation for a constant total concentration has the form

$$\underbrace{u \frac{\partial C_A}{\partial x}}_{1a} + \underbrace{v \frac{\partial C_A}{\partial y}}_{1b} = \underbrace{\frac{\partial}{\partial x} \left[D_{AB} \frac{\partial C_A}{\partial x} \right]}_{2a} + \underbrace{\frac{\partial}{\partial y} \left[D_{AB} \frac{\partial C_A}{\partial y} \right]}_{2b} + \underbrace{\dot{N}_A}_3$$

1. Change in species transport due to advection in x and y directions, <
2. Change in species transport by diffusion in x and y directions, and
3. Rate of species generation.

(b) The special conditions used to reduce the above equations to the boundary layer equations are: *constant properties, incompressible flow, non-reacting species* ($\dot{N}_A = 0$), *without internal heat generation* ($\dot{q} = 0$), *species diffusion has negligible effect on the thermal boundary layer*, *$u(\partial p / \partial x)$ is negligible*. The approximations are,

Velocity boundary layer $\left\{ u \gg v \quad \frac{\partial u}{\partial y} \gg \frac{\partial u}{\partial x}, \frac{\partial v}{\partial y}, \frac{\partial v}{\partial x} \right.$

Thermal b.1.: $\left\{ \frac{\partial T}{\partial y} \gg \frac{\partial T}{\partial x} \right.$ Concentration b.1.: $\left\{ \frac{\partial C_A}{\partial y} \gg \frac{\partial C_A}{\partial x} \right.$

The resulting simplified boundary layer equations are

$$\underbrace{u \frac{\partial T}{\partial x}}_{1a} + \underbrace{v \frac{\partial T}{\partial y}}_{1b} = \underbrace{\alpha \frac{\partial^2 T}{\partial y^2}}_{2a} + \underbrace{\frac{\nu}{c} \left[\frac{\partial u}{\partial y} \right]^2}_3 \quad \underbrace{u \frac{\partial C_A}{\partial x}}_{1c} + \underbrace{v \frac{\partial C_A}{\partial y}}_{1d} = \underbrace{D_{AB} \frac{\partial^2 C_A}{\partial y^2}}_{2b} \quad <$$

where the terms are: 1. Advective transport, 2. Diffusion, and 3. Viscous dissipation.

(c) When viscous dissipation effects are negligible, the two boundary layer equations have identical form. If the boundary conditions for each equation are of the same form, an analogy between heat and mass (species) transfer exists.

PROBLEM 6S.14

KNOWN: Thickness and inclination of a liquid film. Mass density of gas in solution at free surface of liquid.

FIND: (a) Liquid momentum equation and velocity distribution for the x-direction. Maximum velocity, (b) Continuity equation and density distribution of the gas in the liquid, (c) Expression for the local Sherwood number, (d) Total gas absorption rate for the film, (e) Mass rate of NH_3 removal by a water film for prescribed conditions.

SCHEMATIC:

NH_3 (A) – Water (B)

$$L = 2\text{m}$$

$$\delta = 1\text{ mm}$$

$$D = 0.05\text{m}$$

$$W = \pi D = 0.157\text{m}$$

$$\rho_{A,0} = 25\text{ kg/m}^3$$

$$D_{AB} = 2 \times 10^{-9}\text{ m}^2/\text{s}$$

$$\phi = 0^\circ$$

ASSUMPTIONS: (1) Steady-state conditions, (2) The film is in fully developed, laminar flow, (3) Negligible shear stress at the liquid-gas interface, (4) Constant properties, (5) Negligible gas concentration at $x = 0$ and $y = \delta$, (6) No chemical reactions in the liquid, (7) Total mass density is constant, (8) Liquid may be approximated as semi-infinite to gas transport.

PROPERTIES: Table A-6, Water, liquid (300K): $\rho_f = 1/\nu_f = 997\text{ kg/m}^3$, $\mu = 855 \times 10^{-6}\text{ N}\cdot\text{s/m}^2$, $\nu = \mu/\rho_f = 0.855 \times 10^{-6}\text{ m}^2/\text{s}$.

ANALYSIS: (a) For fully developed flow ($v = w = 0$, $\partial u/\partial x = 0$), the x-momentum equation is

$$0 = \partial \tau_{yx} / \partial y + X \quad \text{where} \quad \tau_{yx} = \mu (\partial u / \partial y) \quad \text{and} \quad X = (\rho g) \cos \phi.$$

That is, the momentum equation reduces to a balance between gravitational and shear forces. Hence,

$$\mu \left(\partial^2 u / \partial y^2 \right) = -(\rho g) \cos \phi.$$

Integrating, $\partial u / \partial y = -(g \cos \phi / \nu) y + C_1$ $u = -(g \cos \phi / 2\nu) y^2 + C_1 y + C_2$.

Applying the boundary conditions,

$$\left(\partial u / \partial y \right)_{y=0} = 0 \quad \rightarrow \quad C_1 = 0$$

$$u(\delta) = 0 \quad \rightarrow \quad C_2 = g \cos \phi \frac{\delta^2}{2\nu}.$$

$$\text{Hence,} \quad u = \frac{g \cos \phi}{2\nu} (\delta^2 - y^2) = \frac{g \cos \phi}{2\nu} \delta^2 \left[1 - (y/\delta)^2 \right] \quad <$$

and the maximum velocity exists at $y = 0$,

$$u_{\max} = u(0) = (g \cos \phi \delta^2) / 2\nu. \quad <$$

(b) Species transport within the liquid is influenced by diffusion in the y-direction and advection in the x-direction. Hence, the species continuity equation with u assumed equal to u_{\max} throughout the region of gas penetration is

Continued

PROBLEM 6S.14 (Cont.)

$$u \frac{\partial \rho_A}{\partial x} = D_{AB} \frac{\partial^2 \rho_A}{\partial y^2} \quad \frac{\partial^2 \rho_A}{\partial y^2} = \frac{u_{\max}}{D_{AB}} \frac{\partial \rho_A}{\partial x}.$$

Appropriate boundary conditions are: $\rho_A(x,0) = \rho_{A,o}$ and $\rho_A(x,\infty) = 0$ and the entrance condition is: $\rho_A(0,y) = 0$. The problem is therefore analogous to transient conduction in a semi-infinite medium due to a sudden change in surface temperature. From Section 5.7, the solution is then

$$\frac{\rho_A - \rho_{A,o}}{0 - \rho_{A,o}} = \operatorname{erf} \frac{y}{2(D_{AB}x/u_{\max})^{1/2}} \quad \rho_A = \rho_{A,o} \operatorname{erfc} \frac{y}{2(D_{AB}x/u_{\max})^{1/2}} <$$

(c) The Sherwood number is defined as

$$\operatorname{Sh}_x = \frac{h_{m,x} x}{D_{AB}} \quad \text{where} \quad h_{m,x} \equiv \frac{n''_{A,x}}{\rho_{A,o}} = \frac{-D_{AB} \partial \rho_A / \partial y|_{y=0}}{\rho_{A,o}}$$

$$\left. \frac{\partial \rho_A}{\partial y} \right|_{y=0} = -\rho_{A,o} \frac{2}{(\pi)^{1/2}} \exp \left[-\frac{y^2 u_{\max}}{4 D_{AB} x} \right] \frac{1}{2(D_{AB}x/u_{\max})^{1/2}} \bigg|_{y=0} = -\rho_{A,o} \left[\frac{u_{\max}}{\pi D_{AB} x} \right]^{1/2}.$$

Hence,

$$h_{m,x} = \left[\frac{u_{\max} D_{AB}}{\pi x} \right]^{1/2} \quad \operatorname{Sh}_x = \frac{1}{(\pi)^{1/2}} \left[\frac{u_{\max} x}{D_{AB}} \right]^{1/2} = \frac{1}{(\pi)^{1/2}} \left[\frac{u_{\max} x}{\nu} \right]^{1/2} \left[\frac{\nu}{D_{AB}} \right]^{1/2}$$

and with $\operatorname{Re}_x \equiv u_{\max} x / \nu$,

$$\operatorname{Sh}_x = \left[1/(\pi)^{1/2} \right] \operatorname{Re}_x^{1/2} \operatorname{Sc}^{1/2} = 0.564 \operatorname{Re}_x^{1/2} \operatorname{Sc}^{1/2}. <$$

(d) The total gas absorption rate may be expressed as

$$\dot{n}_A = \bar{h}_{m,x} (W \cdot L) \rho_{A,o}$$

where the average mass transfer convection coefficient is

$$\bar{h}_{m,x} = \frac{1}{L} \int_0^L h_{m,x} dx = \frac{1}{L} \left[\frac{u_{\max} D_{AB}}{\pi} \right]^{1/2} \int_0^L \frac{dx}{x^{1/2}} = \left[\frac{4 u_{\max} D_{AB}}{\pi L} \right]^{1/2}.$$

Hence, the absorption rate per unit width is

$$\dot{n}_A / W = (4 u_{\max} D_{AB} L / \pi)^{1/2} \rho_{A,o}. <$$

(e) From the foregoing results, it follows that the ammonia absorption rate is

$$\dot{n}_A = \left[\frac{4 u_{\max} D_{AB} L}{\pi} \right]^{1/2} W \rho_{A,o} = \left[\frac{4 g \cos \phi \delta^2 D_{AB} L}{2 \pi \nu} \right]^{1/2} W \rho_{A,o}.$$

Substituting numerical values,

$$\dot{n}_A = \left[\frac{4 \times 9.8 \text{ m/s}^2 \times 1 \times (10^{-3} \text{ m})^2 (2 \times 10^{-9} \text{ m}^2/\text{s}) 2 \text{ m}}{2 \pi \times 0.855 \times 10^{-6} \text{ m}^2/\text{s}} \right]^{1/2} (0.157 \text{ m}) 25 \text{ kg/m}^3 = 6.71 \times 10^{-4} \text{ kg/s}. <$$

COMMENTS: Note that $\rho_{A,o} \neq \rho_{A,\infty}$, where $\rho_{A,\infty}$ is the mass density of the gas phase. The value of $\rho_{A,o}$ depends upon the pressure of the gas and the solubility of the gas in the liquid.

PROBLEM 6S.2

KNOWN: Oil properties, journal and bearing temperatures, and journal speed for a lightly loaded journal bearing.

FIND: Maximum oil temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Clearance is much less than journal radius and flow is Couette.

ANALYSIS: The temperature distribution corresponds to the result obtained in the text Example on Couette flow,

$$T(y) = T_0 + \frac{\mu}{2k} U^2 \left[\frac{y}{L} - \left[\frac{y}{L} \right]^2 \right].$$

The position of maximum temperature is obtained from

$$\frac{dT}{dy} = 0 = \frac{\mu}{2k} U^2 \left[\frac{1}{L} - \frac{2y}{L^2} \right]$$

or, $y = L/2$.

The temperature is a maximum at this point since $d^2T/dy^2 < 0$. Hence,

$$T_{\max} = T(L/2) = T_0 + \frac{\mu}{2k} U^2 \left[\frac{1}{2} - \frac{1}{4} \right] = T_0 + \frac{\mu U^2}{8k}$$

$$T_{\max} = 40^\circ\text{C} + \frac{10^{-2} \text{ kg/s} \cdot \text{m} (10 \text{ m/s})^2}{8 \times 0.15 \text{ W/m} \cdot \text{K}}$$

$$T_{\max} = 40.83^\circ\text{C}.$$

<

COMMENTS: Note that T_{\max} *increases* with *increasing* μ and U , *decreases* with *increasing* k , and is *independent* of L .

PROBLEM 6S.3

KNOWN: Diameter, clearance, rotational speed and fluid properties of a lightly loaded journal bearing. Temperature of bearing.

FIND: (a) Temperature distribution in the fluid, (b) Rate of heat transfer from bearing and operating power.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Couette flow.

PROPERTIES: Oil (Given): $\rho = 800 \text{ kg/m}^3$, $\nu = 10^{-5} \text{ m}^2/\text{s}$, $k = 0.13 \text{ W/m}\cdot\text{K}$; $\mu = \rho\nu = 8 \times 10^{-3} \text{ kg/s}\cdot\text{m}$.

ANALYSIS: (a) For Couette flow, the velocity distribution is linear, $u(y) = U(y/L)$, and the energy equation and general form of the temperature distribution are

$$k \frac{d^2 T}{dy^2} = -\mu \left[\frac{du}{dy} \right]^2 = -\mu \left[\frac{U}{L} \right]^2 \quad T = -\frac{\mu}{2k} \left[\frac{U}{L} \right]^2 y^2 + \frac{C_1}{k} y + C_2.$$

Considering the boundary conditions $dT/dy|_{y=L} = 0$ and $T(0) = T_0$, find $C_2 = T_0$ and $C_1 = \mu U^2/L$. Hence,

$$T = T_0 + \left(\mu U^2 \right) / k \left[(y/L) - 1/2 (y/L)^2 \right]. \quad <$$

(b) Applying Fourier's law at $y = 0$, the rate of heat transfer per unit length to the bearing is

$$q' = -k(\pi D) \frac{dT}{dy} \Big|_{y=0} = -(\pi D) \frac{\mu U^2}{L} = -(\pi \times 75 \times 10^{-3} \text{ m}) \frac{8 \times 10^{-3} \text{ kg/s}\cdot\text{m} (14.14 \text{ m/s})^2}{0.25 \times 10^{-3} \text{ m}} = -1507.5 \text{ W/m}$$

where the velocity is determined as

$$U = (D/2)\omega = 0.0375 \text{ m} \times 3600 \text{ rev/min} (2\pi \text{ rad/rev}) / (60 \text{ s/min}) = 14.14 \text{ m/s}.$$

The journal power requirement is

$$P' = F'_{(y=L)} U = \tau_{s(y=L)} \cdot \pi D \cdot U$$

$$P' = 452.5 \text{ kg/s}^2 \cdot \text{m} \left(\pi \times 75 \times 10^{-3} \text{ m} \right) 14.14 \text{ m/s} = 1507.5 \text{ kg}\cdot\text{m/s}^3 = 1507.5 \text{ W/m} \quad <$$

where the shear stress at $y = L$ is

$$\tau_{s(y=L)} = \mu \left(\partial u / \partial y \right)_{y=L} = \mu \frac{U}{L} = 8 \times 10^{-3} \text{ kg/s}\cdot\text{m} \left[\frac{14.14 \text{ m/s}}{0.25 \times 10^{-3} \text{ m}} \right] = 452.5 \text{ kg/s}^2 \cdot \text{m}.$$

COMMENTS: Note that $q' = P'$, which is consistent with the energy conservation requirement.

PROBLEM 6S.4

KNOWN: Conditions associated with the Couette flow of air or water.

FIND: (a) Force and power requirements per unit surface area, (b) Viscous dissipation, (c) Maximum fluid temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Fully-developed Couette flow, (2) Incompressible fluid with constant properties.

PROPERTIES: Table A-4, Air (300K): $\mu = 184.6 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2$, $k = 26.3 \times 10^{-3} \text{ W}/\text{m}\cdot\text{K}$; Table A-6, Water (300K): $\mu = 855 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2$, $k = 0.613 \text{ W}/\text{m}\cdot\text{K}$.

ANALYSIS: (a) The force per unit area is associated with the shear stress. Hence, with the linear velocity profile for Couette flow, $\tau = \mu(du/dy) = \mu(U/L)$.

$$\text{Air:} \quad \tau_{\text{air}} = 184.6 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2 \times \frac{200 \text{ m/s}}{0.005 \text{ m}} = 0.738 \text{ N}/\text{m}^2 \quad <$$

$$\text{Water:} \quad \tau_{\text{water}} = 855 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2 \times \frac{200 \text{ m/s}}{0.005 \text{ m}} = 34.2 \text{ N}/\text{m}^2.$$

With the required power given by $P/A = \tau \cdot U$,

$$\text{Air:} \quad (P/A)_{\text{air}} = (0.738 \text{ N}/\text{m}^2) 200 \text{ m/s} = 147.6 \text{ W}/\text{m}^2 \quad <$$

$$\text{Water:} \quad (P/A)_{\text{water}} = (34.2 \text{ N}/\text{m}^2) 200 \text{ m/s} = 6840 \text{ W}/\text{m}^2.$$

(b) The viscous dissipation is $\mu\Phi = \mu(du/dy)^2 = \mu(U/L)^2$. Hence,

$$\text{Air:} \quad (\mu\Phi)_{\text{air}} = 184.6 \times 10^{-7} \frac{\text{N}\cdot\text{s}}{\text{m}^2} \left[\frac{200 \text{ m/s}}{0.005 \text{ m}} \right]^2 = 2.95 \times 10^4 \text{ W}/\text{m}^3 \quad <$$

$$\text{Water:} \quad (\mu\Phi)_{\text{water}} = 855 \times 10^{-6} \frac{\text{N}\cdot\text{s}}{\text{m}^2} \left[\frac{200 \text{ m/s}}{0.005 \text{ m}} \right]^2 = 1.37 \times 10^6 \text{ W}/\text{m}^3.$$

(c) From the solution to Part 4 of Example 6S.1, the location of the maximum temperature corresponds to $y_{\text{max}} = L/2$. Hence, $T_{\text{max}} = T_0 + \mu U^2 / 8k$ and

$$\text{Air:} \quad (T_{\text{max}})_{\text{air}} = 27^\circ\text{C} + \frac{184.6 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2 (200 \text{ m/s})^2}{8 \times 0.0263 \text{ W}/\text{m}\cdot\text{K}} = 30.5^\circ\text{C} \quad <$$

$$\text{Water:} \quad (T_{\text{max}})_{\text{water}} = 27^\circ\text{C} + \frac{855 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2 (200 \text{ m/s})^2}{8 \times 0.613 \text{ W}/\text{m}\cdot\text{K}} = 34.0^\circ\text{C}.$$

COMMENTS: (1) The viscous dissipation associated with the entire fluid layer, $\mu\Phi(LA)$, must equal the power, P . (2) Although $(\mu\Phi)_{\text{water}} \gg (\mu\Phi)_{\text{air}}$, $k_{\text{water}} \gg k_{\text{air}}$. Hence,

$$T_{\text{max,water}} \approx T_{\text{max,air}}.$$

PROBLEM 6S.5

KNOWN: Velocity and temperature difference of plates maintaining Couette flow. Mean temperature of air, water or oil between the plates.

FIND: (a) Pr·Ec product for each fluid, (b) Pr·Ec product for air with plate at sonic velocity.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Couette flow, (3) Air is at 1 atm.

PROPERTIES: Table A-4, Air (300K, 1atm), $c_p = 1007 \text{ J/kg}\cdot\text{K}$, $\text{Pr} = 0.707$, $\gamma = 1.4$, $R = 287.02 \text{ J/kg}\cdot\text{K}$; Table A-6, Water (300K): $c_p = 4179 \text{ J/kg}\cdot\text{K}$, $\text{Pr} = 5.83$; Table A-5, Engine oil (300K), $c_p = 1909 \text{ J/kg}\cdot\text{K}$, $\text{Pr} = 6400$.

ANALYSIS: The product of the Prandtl and Eckert numbers is dimensionless,

$$\text{Pr} \cdot \text{Ec} = \text{Pr} \frac{U^2}{c_p \Delta T} \sim \frac{\text{m}^2/\text{s}^2}{(\text{J/kg}\cdot\text{K})\text{K}} \sim \frac{\text{m}^2/\text{s}^2}{(\text{kg}\cdot\text{m}^2/\text{s}^2)/\text{kg}}$$

Substituting numerical values, find

	<i>Air</i>	<i>Water</i>	<i>Oil</i>	
Pr·Ec	0.0028	0.0056	13.41	<

(b) For an ideal gas, the speed of sound is

$$c = (\gamma R T)^{1/2}$$

where R , the gas constant for air, is $R_u/M = 8.315 \text{ kJ/kmol}\cdot\text{K}/(28.97 \text{ kg/kmol}) = 287.02 \text{ J/kg}\cdot\text{K}$. Hence, at 300K for air,

$$U = c = (1.4 \times 287.02 \text{ J/kg}\cdot\text{K} \times 300\text{K})^{1/2} = 347.2 \text{ m/s}.$$

For sonic velocities, it follows that

$$\text{Pr} \cdot \text{Ec} = 0.707 \frac{(347.2 \text{ m/s})^2}{1007 \text{ J/kg}\cdot\text{K} \times 25\text{K}} = 3.38. \quad <$$

COMMENTS: From the above results it follows that viscous dissipation effects must be considered in the high speed flow of gases and in oil flows at moderate speeds. For Pr·Ec to be less than 0.1 in air with $\Delta T = 25^\circ\text{C}$, U should be $\lesssim 60 \text{ m/s}$.

PROBLEM 6S.6

KNOWN: Couette flow with moving plate isothermal and stationary plate insulated.

FIND: Temperature of stationary plate and heat flux at the moving plate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Couette flow.

ANALYSIS: The energy equation is given by

$$0 = k \left[\frac{\partial^2 T}{\partial y^2} \right] + \mu \left[\frac{\partial u}{\partial y} \right]^2$$

Integrating twice find the general form of the temperature distribution,

$$\frac{\partial^2 T}{\partial y^2} = -\frac{\mu}{k} \left[\frac{U}{L} \right]^2 \quad \frac{\partial T}{\partial y} = -\frac{\mu}{k} \left[\frac{U}{L} \right]^2 y + C_1$$

$$T(y) = -\frac{\mu}{2k} \left[\frac{U}{L} \right]^2 y^2 + C_1 y + C_2.$$

Consider the boundary conditions to evaluate the constants,

$$\left. \frac{\partial T}{\partial y} \right|_{y=0} = 0 \rightarrow C_1 = 0 \text{ and } T(L) = T_L \rightarrow C_2 = T_L + \frac{\mu}{2k} U^2.$$

Hence, the temperature distribution is

$$T(y) = T_L + \left[\frac{\mu U^2}{2k} \right] \left[1 - \left[\frac{y}{L} \right]^2 \right].$$

The temperature of the lower plate ($y = 0$) is

$$T(0) = T_L + \left[\frac{\mu U^2}{2k} \right]. \quad <$$

The heat flux to the upper plate ($y = L$) is

$$q''(L) = -k \left. \frac{\partial T}{\partial y} \right|_{y=L} = \frac{\mu U^2}{L}. \quad <$$

COMMENTS: The heat flux at the top surface may also be obtained by integrating the viscous dissipation over the fluid layer height. For a control volume about a unit area of the fluid layer,

$$\dot{E}_g'' = \dot{E}_{\text{out}}'' \quad \int_0^L \mu \left[\frac{\partial u}{\partial y} \right]^2 dy = q''(L) \quad q''(L) = \frac{\mu U^2}{L}.$$

PROBLEM 6S.7

KNOWN: Couette flow with heat transfer. Lower (insulated) plate moves with speed U and upper plate is stationary with prescribed thermal conductivity and thickness. Outer surface of upper plate maintained at constant temperature, $T_{sp} = 40^\circ\text{C}$.

FIND: (a) On T - y coordinates, sketch the temperature distribution in the oil and the stationary plate, and (b) An expression for the temperature at the lower surface of the oil film, $T(0) = T_o$, in terms of the plate speed U , the stationary plate parameters (T_{sp} , k_{sp} , L_{sp}) and the oil parameters (μ , k_o , L_o). Determine this temperature for the prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed Couette flow and (3) Incompressible fluid with constant properties.

ANALYSIS: (a) The temperature distribution is shown above with these key features: linear in plate, parabolic in oil film, discontinuity in slope at plate-oil interface, and zero gradient at lower plate surface.

(b) From Example 6S.1, the general solution to the conservation equations for the temperature distribution in the oil film is

$$T_o(y) = -Ay^2 + C_3y + C_4 \quad \text{where} \quad A = \frac{\mu}{2k_o} \left(\frac{U}{L_o} \right)^2$$

and the boundary conditions are,

At $y = 0$, insulated boundary $\left. \frac{dT_o}{dy} \right|_{y=0} = 0; \quad C_3 = 0$

At $y = L_o$, heat fluxes in oil and plate are equal, $q_o''(L_o) = q_{sp}''(L_o)$

Continued...

PROBLEM 6S.7 (Cont.)

$$\left. -k_o \frac{dT_o}{dy} \right)_{y=L_o} = \frac{T_o(L_o) - T_{sp}}{R_{sp}} \quad \left\{ \begin{array}{l} \left. \frac{dT_o}{dy} \right)_{y=L_o} = -2AL_o \\ R_{sp} = L_{sp}/k_{sp} \end{array} \right. \quad T_o(L_o) = -AL_o^2 + C_4$$

$$C_4 = T_{sp} + AL_o^2 \left[1 + 2 \frac{k_o}{L_o} \frac{L_{sp}}{k_{sp}} \right]$$

Hence, the temperature distribution at the lower surface is

$$T_o(0) = -A \cdot 0 + C_4$$

$$T_o(0) = T_{sp} + \frac{\mu}{2k_o} U^2 \left[1 + 2 \frac{k_o}{L_o} \frac{L_{sp}}{k_{sp}} \right] \quad <$$

Substituting numerical values, find

$$T_o(0) = 40^\circ\text{C} + \frac{0.799 \text{ N}\cdot\text{s}/\text{m}^2}{2 \times 0.145 \text{ W}/\text{m}\cdot\text{K}} (5 \text{ m/s})^2 \left[1 + 2 \frac{0.145}{5} \times \frac{3}{1.5} \right] = 116.9^\circ\text{C} \quad <$$

COMMENTS: (1) Give a physical explanation about why the maximum temperature occurs at the lower surface.

(2) Sketch the temperature distribution if the upper plate moved with a speed U while the lower plate is stationary and all other conditions remain the same.

PROBLEM 6S.8

KNOWN: Shaft of diameter 100 mm rotating at 9000 rpm in a journal bearing of 70 mm length. Uniform gap of 1 mm separates the shaft and bearing filled with lubricant. Outer surface of bearing is water-cooled and maintained at $T_{wc} = 30^\circ\text{C}$.

FIND: (a) Viscous dissipation in the lubricant, $\mu\Phi(\text{W/m}^3)$, (b) Heat transfer rate from the lubricant, assuming no heat lost through the shaft, and (c) Temperatures of the bearing and shaft, T_b and T_s .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed Couette flow, (3) Incompressible fluid with constant properties, and (4) Negligible heat lost through the shaft.

ANALYSIS: (a) The viscous dissipation, $\mu\Phi$, Eq. 6S.20, for Couette flow from Example 6S.1, is

$$\mu\Phi = \mu \left(\frac{du}{dy} \right)^2 = \mu \left(\frac{U}{L} \right)^2 = 0.03 \text{ N}\cdot\text{s/m}^2 \left(\frac{47.1 \text{ m/s}}{0.001 \text{ m}} \right)^2 = 6.656 \times 10^7 \text{ W/m}^3 \quad <$$

where the velocity distribution is linear and the tangential velocity of the shaft is

$$U = \pi D N = \pi (0.100 \text{ m}) \times 9000 \text{ rpm} \times (\text{min}/60\text{s}) = 47.1 \text{ m/s}.$$

(b) The heat transfer rate from the lubricant volume \forall through the bearing is

$$q = \mu\Phi \cdot \forall = \mu\Phi (\pi D \cdot L \cdot \ell) = 6.65 \times 10^7 \text{ W/m}^3 (\pi \times 0.100 \text{ m} \times 0.001 \text{ m} \times 0.070 \text{ m}) = 1462 \text{ W} \quad <$$

where $\ell = 70 \text{ mm}$ is the length of the bearing normal to the page.

Continued...

PROBLEM 6S.8 (Cont.)

(c) From Fourier's law, the heat rate through the bearing material of inner and outer diameters, D_i and D_o , and thermal conductivity k_b is, from Eq. (3.27),

$$q_r = \frac{2\pi\ell k_b (T_b - T_{wc})}{\ln(D_o/D_i)}$$

$$T_b = T_{wc} + \frac{q_r \ln(D_o/D_i)}{2\pi\ell k_b}$$

$$T_b = 30^\circ\text{C} + \frac{1462\text{ W} \ln(200/100)}{2\pi \times 0.070\text{ m} \times 45\text{ W/m}\cdot\text{K}} = 81.2^\circ\text{C} \quad <$$

To determine the temperature of the shaft, $T(0) = T_s$, first the temperature distribution must be found beginning with the general solution, Example 6S.1,

$$T(y) = -\frac{\mu}{2k} \left(\frac{U}{L} \right)^2 y^2 + C_3 y + C_4$$

The boundary conditions are, at $y = 0$, the surface is adiabatic

$$\left. \frac{dT}{dy} \right|_{y=0} = 0 \quad C_3 = 0$$

and at $y = L$, the temperature is that of the bearing, T_b

$$T(L) = T_b = -\frac{\mu}{2k} \left(\frac{U}{L} \right)^2 L^2 + 0 + C_4 \quad C_4 = T_b + \frac{\mu}{2k} U^2$$

Hence, the temperature distribution is

$$T(y) = T_b + \frac{\mu}{2k} U^2 \left(1 - \frac{y^2}{L^2} \right)$$

and the temperature at the shaft, $y = 0$, is

$$T_s = T(0) = T_b + \frac{\mu}{2k} U^2 = 81.3^\circ\text{C} + \frac{0.03\text{ N}\cdot\text{s/m}^2}{2 \times 0.15\text{ W/m}\cdot\text{K}} (47.1\text{ m/s})^2 = 303^\circ\text{C} \quad <$$

PROBLEM 6S.9

KNOWN: Couette flow with heat transfer.

FIND: (a) Dimensionless form of temperature distribution, (b) Conditions for which top plate is adiabatic, (c) Expression for heat transfer to lower plate when top plate is adiabatic.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) incompressible fluid with constant properties, (3) Negligible body forces, (4) Couette flow.

ANALYSIS: (a) From Example 6.4, the temperature distribution is

$$T = T_0 + \frac{\mu}{2k} U^2 \left[\frac{y}{L} - \left(\frac{y}{L} \right)^2 \right] + (T_L - T_0) \frac{y}{L}$$

$$\frac{T - T_0}{T_L - T_0} = \frac{\mu U^2}{2k(T_L - T_0)} \left[\frac{y}{L} - \left(\frac{y}{L} \right)^2 \right] + \frac{y}{L}$$

or, with

$$\begin{aligned} \theta &\equiv (T - T_0)/(T_L - T_0), & \eta &\equiv y/L, \\ \text{Pr} &\equiv c_p \mu / k, & \text{Ec} &\equiv U^2 / c_p (T_L - T_0) \\ \theta &= \frac{\text{Pr} \cdot \text{Ec}}{2} (\eta - \eta^2) + \eta = \eta \left[1 + \frac{1}{2} \text{Pr} \cdot \text{Ec} (1 - \eta) \right] \end{aligned} \quad (1) <$$

(b) For there to be zero heat transfer at the top plate, $(dT/dy)_{y=L} = 0$. Hence, $(d\theta/d\eta)_{\eta=1} = 0$.

$$\left. \frac{d\theta}{d\eta} \right|_{\eta=1} = \frac{\text{Pr} \cdot \text{Ec}}{2} (1 - 2\eta) \Big|_{\eta=1} + 1 = -\frac{\text{Pr} \cdot \text{Ec}}{2} + 1 = 0$$

There is no heat transfer at the top plate if,

$$\text{Ec} \cdot \text{Pr} = 2. \quad (2) <$$

(c) The heat transfer rate to the lower plate (per unit area) is

$$\begin{aligned} q_0'' &= -k \left. \frac{dT}{dy} \right|_{y=0} = -k \frac{(T_L - T_0)}{L} \left. \frac{d\theta}{d\eta} \right|_{\eta=0} \\ q_0'' &= -k \frac{T_L - T_0}{L} \left[\frac{\text{Pr} \cdot \text{Ec}}{2} (1 - 2\eta) \Big|_{\eta=0} + 1 \right] \\ q_0'' &= -k \frac{T_L - T_0}{L} \left(\frac{\text{Pr} \cdot \text{Ec}}{2} + 1 \right) = -2k (T_L - T_0) / L \end{aligned} <$$

Continued...

PROBLEM 6S.9 (Cont.)

(d) Using Eq. (1), the dimensionless temperature distribution is plotted as a function of dimensionless distance, $\eta = y/L$. When $Pr \cdot Ec = 0$, there is no dissipation and the temperature distribution is linear, so that heat transfer is by conduction only. As $Pr \cdot Ec$ increases, viscous dissipation becomes more important. When $Pr \cdot Ec = 2$, heat transfer to the upper plate is zero. When $Pr \cdot Ec > 2$, the heat rate is out of the oil film at both surfaces.

PROBLEM 7.1

KNOWN: Temperature and velocity of fluids in parallel flow over a flat plate.

FIND: (a) Velocity and thermal boundary layer thicknesses at a prescribed distance from the leading edge, and (b) For each fluid plot the boundary layer thicknesses as a function of distance.

SCHEMATIC:

ASSUMPTIONS: (1) Transition Reynolds number is 5×10^5 .

PROPERTIES: Table A.4, Air (300 K, 1 atm): $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 0.707$; Table A.6, Water (300 K): $\nu = \mu/\rho = 855 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2/997 \text{ kg}/\text{m}^3 = 0.858 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 5.83$; Table A.5, Engine Oil (300 K): $\nu = 550 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 6400$; Table A.5, Mercury (300 K): $\nu = 0.113 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 0.0248$.

ANALYSIS: (a) If the flow is laminar, the following expressions may be used to compute δ and δ_t , respectively,

$$\delta = \frac{5x}{\text{Re}_x^{1/2}} \quad \delta_t = \frac{\delta}{\text{Pr}^{1/3}}$$

where

$$\text{Re}_x = \frac{u_\infty x}{\nu} = \frac{1 \text{ m/s}(0.04 \text{ m})}{\nu} = \frac{0.04 \text{ m}^2/\text{s}}{\nu}$$

Fluid	Re_x	δ (mm)	δ_t (mm)	<
Air	2517	3.99	4.48	
Water	4.66×10^4	0.93	0.52	
Oil	72.7	23.5	1.27	
Mercury	3.54×10^5	0.34	1.17	

(b) Using IHT with the foregoing equations, the boundary layer thicknesses are plotted as a function of distance from the leading edge, x .

COMMENTS: (1) Note that $\delta \approx \delta_t$ for air, $\delta > \delta_t$ for water, $\delta \gg \delta_t$ for oil, and $\delta < \delta_t$ for mercury. As expected, the boundary layer thicknesses increase with increasing distance from the leading edge.

(2) The value of δ_t for mercury should be viewed as a rough approximation since the expression for δ/δ_t was derived subject to the approximation that $\text{Pr} > 0.6$.

PROBLEM 7.2

KNOWN: Temperature and velocity of engine oil. Temperature and length of flat plate.

FIND: (a) Velocity and thermal boundary layer thickness at trailing edge, (b) Heat flux and surface shear stress at trailing edge, (c) Total drag force and heat transfer per unit plate width, and (d) Plot the boundary layer thickness and local values of the shear stress, convection coefficient, and heat flux as a function of x for $0 \leq x \leq 1$ m.

SCHEMATIC:

ASSUMPTIONS: (1) Critical Reynolds number is 5×10^5 , (2) Flow over top and bottom surfaces.

PROPERTIES: Table A.5, Engine Oil ($T_f = 333$ K): $\rho = 864 \text{ kg/m}^3$, $\nu = 86.1 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.140 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 1081$.

ANALYSIS: (a) Calculate the Reynolds number to determine nature of the flow,

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{0.1 \text{ m/s} \times 1 \text{ m}}{86.1 \times 10^{-6} \text{ m}^2/\text{s}} = 1161$$

Hence the flow is laminar at $x = L$. From Eqs. 7.19 and 7.24,

$$\delta = 5L \text{Re}_L^{-1/2} = 5(1 \text{ m})(1161)^{-1/2} = 0.147 \text{ m} \quad <$$

$$\delta_t = \delta \text{Pr}^{-1/3} = 0.147 \text{ m}(1081)^{-1/3} = 0.0143 \text{ m} \quad <$$

(b) The local convection coefficient, Eq. 7.23, and heat flux at $x = L$ are

$$h_L = \frac{k}{L} 0.332 \text{Re}_L^{1/2} \text{Pr}^{1/3} = \frac{0.140 \text{ W/m}\cdot\text{K}}{1 \text{ m}} 0.332(1161)^{1/2} (1081)^{1/3} = 16.25 \text{ W/m}^2 \cdot \text{K}$$

$$q_x'' = h_L (T_s - T_\infty) = 16.25 \text{ W/m}^2 \cdot \text{K} (20 - 100)^\circ \text{C} = -1300 \text{ W/m}^2 \quad <$$

Also, the local shear stress is, from Eq. 7.20,

$$\tau_{s,L} = \frac{\rho u_\infty^2}{2} 0.664 \text{Re}_L^{-1/2} = \frac{864 \text{ kg/m}^3}{2} (0.1 \text{ m/s})^2 0.664(1161)^{-1/2}$$

$$\tau_{s,L} = 0.0842 \text{ kg/m} \cdot \text{s}^2 = 0.0842 \text{ N/m}^2 \quad <$$

(c) With the drag force per unit width given by $D' = 2L\bar{\tau}_{s,L}$ where the factor of 2 is included to account for both sides of the plate, it follows from Eq. 7.29 that

$$D' = 2L \left(\rho u_\infty^2 / 2 \right) 1.328 \text{Re}_L^{-1/2} = (1 \text{ m}) 864 \text{ kg/m}^3 (0.1 \text{ m/s})^2 1.328(1161)^{-1/2} = 0.337 \text{ N/m} \quad <$$

For laminar flow, the average value \bar{h}_L over the distance 0 to L is twice the local value, h_L ,

$$\bar{h}_L = 2h_L = 32.5 \text{ W/m}^2 \cdot \text{K}$$

The total heat transfer rate per unit width of the plate is

$$q' = 2L\bar{h}_L (T_s - T_\infty) = 2(1 \text{ m}) 32.5 \text{ W/m}^2 \cdot \text{K} (20 - 100)^\circ \text{C} = -5200 \text{ W/m} \quad <$$

Continued...

PROBLEM 7.2 (Cont.)

(c) Using IHT with the foregoing equations, the boundary layer thickness, and local values of the convection coefficient and heat flux were calculated and plotted as a function of x .

COMMENTS: (1) Note that since $Pr \gg 1$, $\delta \gg \delta_t$. That is, for the high Prandtl liquids, the velocity boundary layer will be much thicker than the thermal boundary layer.

(2) A copy of the *IHT Workspace* used to generate the above plot is shown below.

```
// Boundary layer thickness, delta
delta = 5 * x * Rex ^0.5
delta_mm = delta * 1000
delta_plot = delta_mm * 10      // Scaling parameter for convenience in plotting

// Convection coefficient and heat flux, q''x
q''x = hx * (Ts - Tinf)
Nux = 0.332 * Rex^0.5 * Pr^(1/3)
Nux = hx * x / k
hx_plot = 100 * hx              // Scaling parameter for convenience in plotting
q''x_plot = (-1) * q''x         // Scaling parameter for convenience in plotting

// Reynolds number
Rex = uinf * x / nu

// Properties Tool: Engine oil
// Engine Oil property functions : From Table A.5
// Units: T(K)
rho = rho_T("Engine Oil", Tf)    // Density, kg/m^3
cp = cp_T("Engine Oil", Tf)      // Specific heat, J/kg·K
nu = nu_T("Engine Oil", Tf)      // Kinematic viscosity, m^2/s
k = k_T("Engine Oil", Tf)        // Thermal conductivity, W/m·K
Pr = Pr_T("Engine Oil", Tf)      // Prandtl number

// Assigned variables
Tf = (Ts + Tinf) / 2             // Film temperature, K
Tinf = 100 + 273                 // Freestream temperature, K
Ts = 20 + 273                    // Surface temperature, K
uinf = 0.1                       // Freestream velocity, m/s
x = 1                            // Plate length, m
```

PROBLEM 7.3

KNOWN: Velocity and temperature of air in parallel flow over a flat plate.

FIND: (a) Velocity boundary layer thickness at selected stations. Distance at which boundary layers merge for plates separated by $H = 3 \text{ mm}$. (b) Surface shear stress and $v(\delta)$ at selected stations.

SCHEMATIC:

ASSUMPTIONS: (1) Steady flow, (2) Boundary layer approximations are valid, (3) Flow is laminar.

PROPERTIES: Table A-4, Air (300 K, 1 atm): $\rho = 1.161 \text{ kg/m}^3$, $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: (a) For laminar flow,

$$\delta = \frac{5x}{\text{Re}_x^{1/2}} = \frac{5}{(u_\infty/\nu)^{1/2}} x^{1/2} = \frac{5x^{1/2}}{(25 \text{ m/s}/15.89 \times 10^{-6} \text{ m}^2/\text{s})^{1/2}} = 3.99 \times 10^{-3} x^{1/2}.$$

$x \text{ (m)}$	0.001	0.01	0.1
$\delta \text{ (mm)}$	0.126	0.399	1.262

Boundary layer merger occurs at $x = x_m$ when $\delta = 1.5 \text{ mm}$. Hence

$$x_m^{1/2} = \frac{0.0015 \text{ m}}{3.99 \times 10^{-3} \text{ m}^{1/2}} = 0.376 \text{ m}^{1/2} \quad x_m = 141 \text{ mm.} \quad <$$

(b) The shear stress is

$$\tau_{s,x} = 0.664 \frac{\rho u_\infty^2 / 2}{\text{Re}_x^{1/2}} = 0.664 \frac{\rho u_\infty^2 / 2}{(u_\infty/\nu)^{1/2} x^{1/2}} = \frac{0.664 \times 1.161 \text{ kg/m}^3 (25 \text{ m/s})^2 / 2}{(25 \text{ m/s}/15.89 \times 10^{-6} \text{ m}^2/\text{s})^{1/2} x^{1/2}} = \frac{0.192}{x^{1/2}} \left(\text{N/m}^2 \right).$$

$x \text{ (m)}$	0.001	0.01	0.1
$\tau_{s,x} \text{ (N/m}^2\text{)}$	6.07	1.92	0.61

The velocity distribution in the boundary layer is $v = (1/2) (\nu u_\infty / x)^{1/2} (\eta df/d\eta - f)$. At $y = \delta$, $\eta \approx 5.0$, $f \approx 3.24$, $df/d\eta \approx 0.991$.

$$v = \frac{0.5}{x^{1/2}} (15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 25 \text{ m/s})^{1/2} (5.0 \times 0.991 - 3.28) = (0.0167 / x^{1/2}) \text{ m/s.}$$

$x \text{ (m)}$	0.001	0.01	0.1
$v \text{ (m/s)}$	0.528	0.167	0.053

COMMENTS: (1) $v \ll u_\infty$ and $\delta \ll x$ are consistent with BL approximations. Note, $v \rightarrow \infty$ as $x \rightarrow 0$ and approximations breakdown very close to the leading edge. (2) Since $\text{Re}_{x_m} = 2.22 \times 10^5$, laminar BL model is valid. (3) Above expressions are approximations for flow between parallel plates, since $du_\infty/dx > 0$ and $dp/dx < 0$.

PROBLEM 7.4

KNOWN: Liquid metal in parallel flow over a flat plate.

FIND: An expression for the local Nusselt number.

SCHEMATIC:

ASSUMPTIONS: (1) Steady, incompressible flow, (2) $\delta \ll \delta_t$, hence $u(y) \approx u_\infty$, (3) Boundary layer approximations are valid, (4) Constant properties.

ANALYSIS: The boundary layer energy equation is

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2}.$$

Assuming $u(y) = u_\infty$, it follows that $v = 0$ and the energy equation becomes

$$u_\infty \frac{\partial T}{\partial x} = \alpha \frac{\partial^2 T}{\partial y^2} \quad \text{or} \quad \frac{\partial T}{\partial x} = \frac{\alpha}{u_\infty} \frac{\partial^2 T}{\partial y^2}.$$

Boundary Conditions: $T(x, 0) = T_s$, $T(x, \infty) = T_\infty$.

Initial Condition: $T(0, y) = T_\infty$.

The differential equation is analogous to that for transient one-dimensional conduction in a plane wall, and the conditions are analogous to those of Fig. 5.7, Case (1). Hence the solution is given by Eqs.

5.57 and 5.58. Substituting y for x , x for t , T_∞ for T_i , and α/u_∞ for α , the boundary layer temperature and the surface heat flux become

$$\frac{T(x, y) - T_s}{T_\infty - T_s} = \text{erf} \left[\frac{y}{2(\alpha x/u_\infty)^{1/2}} \right]$$

$$q_s'' = \frac{k(T_s - T_\infty)}{(\pi \alpha x/u_\infty)^{1/2}}.$$

Hence, with
$$\text{Nu}_x \equiv \frac{h x}{k} = \frac{q_s'' x}{(T_s - T_\infty) k}$$

$$\text{find} \quad \text{Nu}_x = \frac{x}{(\pi \alpha x/u_\infty)^{1/2}} = \frac{(xu_\infty)^{1/2}}{\pi^{1/2} (k/\rho c_p)^{1/2}} = \frac{1}{\pi^{1/2}} \left[\frac{\rho u_\infty x}{\mu} \cdot \frac{c_p \mu}{k} \right]^{1/2}$$

$$\text{Nu}_x = 0.564 (\text{Re}_x \text{Pr})^{1/2} = 0.564 \text{Pe}^{1/2}$$

<

where $\text{Pe} = \text{Re} \cdot \text{Pr}$ is the Peclet number.

COMMENTS: Because k is very large, axial conduction effects may not be negligible. That is, the $\alpha \partial^2 T / \partial x^2$ term of the energy equation may be important.

PROBLEM 7.5

KNOWN: Form of velocity profile for flow over a flat plate.

FIND: (a) Expression for profile in terms of u_∞ and δ , (b) Expression for $\delta(x)$, (c) Expression for $C_{f,x}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady state conditions, (2) Constant properties, (3) Incompressible flow, (4) Boundary layer approximations are valid.

ANALYSIS: (a) From the boundary conditions

$$u(x, 0) = 0 \rightarrow C_1 = 0 \quad \text{and} \quad u(x, \delta) = u_\infty \rightarrow C_2 = u_\infty / \delta.$$

Hence, $u = u_\infty (y/\delta)$. <

(b) From the momentum integral equation for a flat plate

$$\begin{aligned} \frac{d}{dx} \int_0^\delta (u_\infty - u) u \, dy &= \tau_s / \rho \\ u_\infty^2 \frac{d}{dx} \int_0^\delta \left(1 - \frac{u}{u_\infty}\right) \frac{u}{u_\infty} \, dy &= \frac{\mu}{\rho} \frac{\partial u}{\partial y} \bigg|_{y=0} = \frac{\nu u_\infty}{\delta} \\ u_\infty^2 \frac{d}{dx} \int_0^\delta \left(1 - \frac{y}{\delta}\right) \frac{y}{\delta} \, dy &= \frac{\nu u_\infty}{\delta} \\ u_\infty^2 \frac{d}{dx} \left[\left(\frac{y^2}{2\delta} - \frac{y^3}{3\delta^2} \right) \right]_0^\delta &= \frac{\mu u_\infty}{\delta} \quad \text{or} \quad \frac{u_\infty}{6} \frac{d\delta}{dx} = \frac{\nu}{\delta}. \end{aligned}$$

Separating and integrating, find

$$\int_0^\delta \delta \, d\delta = \frac{6\nu}{u_\infty} \int_0^x dx \quad \delta = \left(\frac{12\nu x}{u_\infty} \right)^{1/2} = 3.46 x \left(\frac{\nu}{u_\infty x} \right)^{1/2} = 3.46 x \text{Re}_x^{-1/2}. \quad <$$

(c) The shear stress at the wall is

$$\tau_s = \mu \frac{\partial u}{\partial y} \bigg|_{y=0} = \mu \frac{u_\infty}{\delta} = \frac{\mu u_\infty}{3.46 x} \text{Re}_x^{1/2}$$

and the friction coefficient is

$$C_{f,x} = \frac{\tau_s}{\rho u_\infty^2 / 2} = \frac{\mu}{\rho u_\infty x} \frac{2}{3.46} \text{Re}_x^{1/2} = 0.578 \text{Re}_x^{-1/2}. \quad <$$

COMMENTS: The foregoing results underpredict those associated with the exact solution

$$\left(\delta = 4.96 x \text{Re}_x^{-1/2}, \, C_{f,x} = 0.664 \text{Re}_x^{-1/2} \right) \text{ and the cubic profile } \left(\delta = 4.64 x \text{Re}_x^{-1/2}, \, C_{f,x} = 0.646 \text{Re}_x^{-1/2} \right).$$

PROBLEM 7.6

KNOWN: Velocity and temperature profiles and shear stress-boundary layer thickness relation for turbulent flow over a flat plate.

FIND: (a) Expressions for hydrodynamic boundary layer thickness and average friction coefficient, (b) Expressions for local and average Nusselt numbers.

SCHEMATIC:

ASSUMPTIONS: (1) Steady flow, (2) Constant properties, (3) Fully turbulent boundary layer, (4) Incompressible flow, (5) Isothermal plate, (6) Negligible viscous dissipation, (7) $\delta \approx \delta_t$.

ANALYSIS: (a) The momentum integral equation is

$$\rho u_{\infty}^2 \frac{d}{dx} \int_0^{\delta} \left(1 - \frac{u}{u_{\infty}}\right) \frac{u}{u_{\infty}} dy = \tau_s.$$

Substituting the expression for the wall shear stress

$$\begin{aligned} \rho u_{\infty}^2 \frac{d}{dx} \int_0^{\delta} \left[1 - \left(\frac{y}{\delta}\right)^{1/7}\right] \left(\frac{y}{\delta}\right)^{1/7} dy &= 0.0228 \rho u_{\infty}^2 \left(\frac{u_{\infty} \delta}{\nu}\right)^{-1/4} \\ \frac{d}{dx} \int_0^{\delta} \left[\left(\frac{y}{\delta}\right)^{1/7} - \left(\frac{y}{\delta}\right)^{2/7}\right] dy &= \frac{d}{dx} \left[\frac{7}{8} \frac{y^{8/7}}{\delta^{1/7}} - \frac{7}{9} \frac{y^{9/7}}{\delta^{2/7}}\right] \Big|_0^{\delta} \\ \frac{d}{dx} \left(\frac{7}{8} \delta - \frac{7}{9} \delta\right) &= 0.0228 \left(\frac{u_{\infty} \delta}{\nu}\right)^{-1/4} \\ \frac{7}{72} \frac{d\delta}{dx} &= 0.0228 \left(\frac{\nu}{u_{\infty}}\right)^{1/4} \delta^{-1/4} \quad \frac{7}{72} \int_0^{\delta} \delta^{1/4} d\delta = 0.0228 \left(\frac{\nu}{u_{\infty}}\right)^{1/4} \int_0^x dx \\ \frac{7}{72} \times \frac{4}{5} \delta^{5/4} &= 0.0228 \left(\frac{\nu}{u_{\infty}}\right)^{1/4} x, \quad \delta = 0.376 \left(\frac{\nu}{u_{\infty}}\right)^{1/5} x^{4/5}, \quad \frac{\delta}{x} = 0.376 \text{Re}_x^{-1/5}. < \end{aligned}$$

Knowing δ , it follows

$$\begin{aligned} \tau_s &= 0.0228 \rho u_{\infty}^2 \left(\frac{u_{\infty}}{\nu}\right)^{-1/4} \left[0.376 x \text{Re}_x^{-1/5}\right]^{-1/4} \\ C_{f,x} &= \frac{\tau_s}{\rho u_{\infty}^2 / 2} = 0.0456 \left[0.376 \frac{u_{\infty}}{\nu} \left(\frac{u_{\infty}}{\nu}\right)^{-1/5} x x^{-1/5}\right]^{-1/4} = 0.0582 \text{Re}_x^{-1/5}. \end{aligned}$$

Continued

PROBLEM 7.6 (Cont.)

The average friction coefficient is then

$$\begin{aligned}\bar{C}_{f,x} &= \frac{1}{x} \int_0^x C_{f,x} dx = \frac{1}{x} 0.0582 \left(\frac{u_\infty}{\nu} \right)^{-1/5} \int_0^x x^{-1/5} dx \\ \bar{C}_{f,x} &= \frac{1}{x} 0.0582 \left(\frac{u_\infty}{\nu} \right)^{-1/5} x^{4/5} \left(\frac{5}{4} \right) = 0.073 \text{Re}_x^{-1/5}.\end{aligned}$$

(b) The energy integral equation for turbulent flow is

$$\frac{d}{dx} \int_0^{\delta_t} u(T_\infty - T) dy = \frac{q_s''}{\rho c_p} = -\frac{h}{\rho c_p} (T_s - T_\infty).$$

Hence,

$$\begin{aligned}u_\infty \frac{d}{dx} \int_0^{\delta_t} \frac{u}{u_\infty} \frac{T - T_\infty}{T_s - T_\infty} dy &= u_\infty \frac{d}{dx} \int_0^{\delta_t} (y/\delta)^{1/7} [1 - (y/\delta_t)^{1/7}] dy = \frac{h}{\rho c_p} \\ u_\infty \frac{d}{dx} \left[\frac{7}{8} \frac{\delta_t^{8/7}}{\delta^{1/7}} - \frac{7}{9} \frac{\delta_t^{8/7}}{\delta^{1/7}} \right] &= \frac{h}{\rho c_p}\end{aligned}$$

or, with $\xi \equiv \delta_t / \delta$,

$$u_\infty \frac{d}{dx} \left[\frac{7}{8} \xi^{8/7} - \frac{7}{9} \xi^{8/7} \right] = \frac{h}{\rho c_p} \quad u_\infty \frac{d}{dx} \left[\frac{7}{72} \xi^{8/7} \right] = \frac{h}{\rho c_p}.$$

Hence, with $\xi \approx 1$ and $\delta/x = 0.376 \text{Re}_x^{-1/5}$,

$$\begin{aligned}\frac{7}{72} u_\infty (0.376) \left(\frac{u_\infty}{\nu} \right)^{-1/5} \frac{d(x^{4/5})}{dx} &= \frac{h}{\rho c_p} \\ h &= 0.0292 \rho c_p u_\infty \text{Re}_x^{-1/5} = 0.0292 \frac{k}{x} \frac{\nu}{\alpha} \frac{u_\infty x}{\nu} \text{Re}_x^{-1/5} \\ \text{Nu}_x = \frac{hx}{k} &= 0.0292 \text{Re}_x^{4/5} \text{Pr}.\end{aligned}$$

Hence,

$$\begin{aligned}\bar{h}_x &= \frac{1}{x} \int_0^x h dx = \frac{0.0292 \text{Pr}}{x} k \left(\frac{u_\infty}{\nu} \right)^{4/5} \int_0^x x^{-1/5} dx = 0.0292 \frac{k}{x} \text{Pr} \left(\frac{u_\infty x}{\nu} \right)^{4/5} \frac{5}{4} \\ \bar{\text{Nu}}_x = \frac{\bar{h}_x x}{k} &= 0.037 \text{Re}_x^{4/5} \text{Pr}.\end{aligned}$$

COMMENTS: (1) The foregoing results are in excellent agreement with empirical correlations, except that use of $\text{Pr}^{1/3}$ instead of Pr , would be more appropriate. This result arose because of the assumption $\delta \approx \delta_t$, which is only valid for $\text{Pr} \approx 1$.

(2) Note that the $1/7$ profile breaks down at the surface. For example,

$$\left. \frac{\partial(u/u_\infty)}{\partial y} \right|_{y=0} = \frac{1}{7} \delta^{-1/7} y^{-6/7} = \infty$$

or $\tau_s = \infty$. Despite this unrealistic characteristic of the profile, its use with integral methods provides excellent results.

PROBLEM 7.7

KNOWN: Parallel flow over a flat plate and two locations representing a short span x_1 to x_2 where $(x_2 - x_1) \ll L$.

FIND: Three different expressions for the average heat transfer coefficient over the short span x_1 to x_2 , \bar{h}_{1-2} .

SCHEMATIC:

ASSUMPTIONS: (1) Parallel flow over a flat plate.

ANALYSIS: The heat rate per unit width for the span can be written as

$$q'_{1-2} = \bar{h}_{1-2} (x_2 - x_1) (T_s - T_\infty) \quad (1)$$

where \bar{h}_{1-2} is the average heat transfer coefficient over the span and can be evaluated in either of the following three ways:

(a) *Local coefficient at $\bar{x} = (x_1 + x_2)/2$.* If the span is very short, it is reasonable to assume that

$$\bar{h}_{1-2} \approx h_{\bar{x}} \quad (2)$$

where $h_{\bar{x}}$ is the local convection coefficient at the mid-point of the span.

(b) *Local coefficients at x_1 and x_2 .* If the span is very short it is reasonable to assume that \bar{h}_{1-2} is the average of the local values at the ends of the span,

$$\bar{h}_{1-2} \approx [h_{x1} + h_{x2}] / 2. \quad (3)$$

(c) *Average coefficients for x_1 and x_2 .* The heat rate for the span can also be written as

$$q'_{1-2} = q'_{0-2} - q'_{0-1} \quad (4)$$

where the rate q'_{0-x} denotes the heat rate for the plate over the distance from 0 to x . In terms of heat transfer coefficients, find

$$\begin{aligned} \bar{h}_{1-2} \cdot (x_2 - x_1) &= \bar{h}_2 \cdot x_2 - \bar{h}_1 \cdot x_1 \\ \bar{h}_{1-2} &= \bar{h}_2 \frac{x_2}{x_2 - x_1} - \bar{h}_1 \frac{x_1}{x_2 - x_1} \end{aligned} \quad (5)$$

where \bar{h}_1 and \bar{h}_2 are the average coefficients from 0 to x_1 and x_2 , respectively.

COMMENTS: Eqs. (2) and (3) are approximate and work better when the span is small and the flow is turbulent rather than laminar ($h_x \sim x^{-0.2}$ vs $h_x \sim x^{-0.5}$). Of course, we require that $x_c < x_1, x_2$ or $x_c > x_1, x_2$; that is, the approximations are inappropriate around the transition region. Eq. (5) is an exact relationship, which applies under any conditions.

PROBLEM 7.8

KNOWN: Flat plate comprised of rectangular modules of surface temperature T_s , thickness a and length b cooled by air at 25°C and a velocity of 30 m/s . Prescribed thermophysical properties of the module material.

FIND: (a) Required power generation for the module positioned 700 mm from the leading edge of the plate and (b) Maximum temperature in this module.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar flow at leading edge of plate, (2) Transition Reynolds number of 5×10^5 , (3) Heat transfer is one-dimensional in y -direction within each module, (4) \dot{q} is uniform within module, (5) Negligible radiation heat transfer.

PROPERTIES: Module material (given): $k = 5.2\text{ W/m}\cdot\text{K}$, $c_p = 320\text{ J/kg}\cdot\text{K}$, $\rho = 2300\text{ kg/m}^3$; Table A-4, Air ($\bar{T}_f = (T_s + T_\infty)/2 = 360\text{ K}$, 1 atm): $k = 0.0308\text{ W/m}\cdot\text{K}$, $\nu = 22.02 \times 10^{-6}\text{ m}^2/\text{s}$, $\text{Pr} = 0.698$.

ANALYSIS: (a) The module power generation follows from an energy balance on the module surface,

$$q_{\text{conv}}'' = q_{\text{gen}}''$$

$$\bar{h}(T_s - T_\infty) = \dot{q} \cdot a \quad \text{or} \quad \dot{q} = \frac{\bar{h}(T_s - T_\infty)}{a}$$

To select a convection correlation for estimating \bar{h} , first find the Reynolds numbers at $x = L$.

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{30\text{ m/s} \times 0.70\text{ m}}{22.02 \times 10^{-6}\text{ m}^2/\text{s}} = 9.537 \times 10^5$$

Since the flow is turbulent over the module, the approximation $\bar{h} \approx h_x(L + b/2)$ is appropriate, with

$$\text{Re}_{L+b/2} = \frac{30\text{ m/s} \times (0.700 + 0.050/2)\text{ m}}{22.02 \times 10^{-6}\text{ m}^2/\text{s}} = 9.877 \times 10^5$$

Using the turbulent flow correlation with $x = L + b/2 = 0.725\text{ m}$,

$$\text{Nu}_x = \frac{h_x x}{k} = 0.0296 \text{Re}_x^{4/5} \text{Pr}^{1/3}$$

$$\text{Nu}_x = 0.0296 (9.877 \times 10^5)^{4/5} (0.698)^{1/3} = 1640$$

$$\bar{h} \approx h_x = \frac{\text{Nu}_x k}{x} = \frac{1640 \times 0.0308\text{ W/m}\cdot\text{K}}{0.725} = 69.7\text{ W/m}^2\cdot\text{K}$$

Continued

PROBLEM 7.8 (Cont.)

Hence,

$$\dot{q} = \frac{69.7 \text{ W/m}^2 \cdot \text{K} (150 - 25) \text{ K}}{0.010 \text{ m}} = 8.713 \times 10^5 \text{ W/m}^3. \quad <$$

(b) The maximum temperature within the module occurs at the surface next to the insulation ($y = 0$). For one-dimensional conduction with thermal energy generation, use Eq. 3.42 to obtain

$$T(0) = \frac{\dot{q} a^2}{2k} + T_s = \frac{8.713 \times 10^5 \text{ W/m}^3 \times (0.010 \text{ m})^2}{2 \times 5.2 \text{ W/m} \cdot \text{K}} + 150^\circ \text{C} = 158.4^\circ \text{C}. \quad <$$

COMMENTS: An alternative approach for estimating the average heat transfer coefficient for the module follows from the relation

$$\dot{q}_{\text{module}} = \dot{q}_{0 \rightarrow L+b} - \dot{q}_{0 \rightarrow L} \quad \text{or} \quad \bar{h} \cdot b = \bar{h}_{L+b} \cdot (L+b) - \bar{h}_L \cdot L$$

Recognizing that laminar and turbulent flow conditions exist, the appropriate correlation is

$$\overline{\text{Nu}}_x = \left(0.037 \text{Re}_x^{4/5} - 871 \right) \text{Pr}^{1/3}$$

With $x = L + b$ and $x = L$, find

$$\bar{h}_{L+b} = 54.79 \text{ W/m}^2 \cdot \text{K} \quad \text{and} \quad \bar{h}_L = 53.73 \text{ W/m}^2 \cdot \text{K}.$$

Hence,

$$\bar{h} = \left[54.79 \frac{0.750}{0.050} - 53.73 \frac{0.700}{0.05} \right] \text{ W/m}^2 \cdot \text{K} = 69.7 \text{ W/m}^2 \cdot \text{K}.$$

which is in excellent agreement with the approximate result employed in part (a).

PROBLEM 7.9

KNOWN: Dimensions and surface temperature of electrically heated strips. Temperature and velocity of air in parallel flow.

FIND: (a) Rate of convection heat transfer from first, fifth and tenth strips as well as from all the strips, (b) For air velocities of 2, 5 and 10 m/s, determine the convection heat rates for all the locations of part (a), and (c) Repeat the calculations of part (b), but under conditions for which the flow is fully turbulent over the entire array of strips.

SCHEMATIC:

ASSUMPTIONS: (1) Top surface is smooth, (2) Bottom surface is adiabatic, (3) Critical Reynolds number is 5×10^5 , (4) Negligible radiation.

PROPERTIES: Table A.4, Air ($T_f = 535$ K, 1 atm): $\nu = 43.54 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0429 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.683$.

ANALYSIS: (a) The location of transition is determined from

$$x_c = 5 \times 10^5 \frac{\nu}{u_\infty} = 5 \times 10^5 \frac{43.54 \times 10^{-6} \text{ m}^2/\text{s}}{2 \text{ m/s}} = 10.9 \text{ m}$$

Since $x_c \gg L = 0.25 \text{ m}$, the air flow is laminar over the entire heater. For the *first* strip, $q_1 = \bar{h}_1 (\Delta L \times w)(T_s - T_\infty)$ where \bar{h}_1 is obtained from

$$\bar{h}_1 = \frac{k}{\Delta L} 0.664 \text{Re}_x^{1/2} \text{Pr}^{1/3}$$

$$\bar{h}_1 = \frac{0.0429 \text{ W/m}\cdot\text{K}}{0.01 \text{ m}} \times 0.664 \left(\frac{2 \text{ m/s} \times 0.01 \text{ m}}{43.54 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{1/2} (0.683)^{1/3} = 53.8 \text{ W/m}^2 \cdot \text{K}$$

$$q_1 = 53.8 \text{ W/m}^2 \cdot \text{K} (0.01 \text{ m} \times 0.2 \text{ m}) (500 - 25)^\circ \text{C} = 51.1 \text{ W} \quad <$$

For the *fifth* strip, $q_5 = q_{0-5} - q_{0-4}$,

$$q_5 = \bar{h}_{0-5} (5\Delta L \times w)(T_s - T_\infty) - \bar{h}_{0-4} (4\Delta L \times w)(T_s - T_\infty)$$

$$q_5 = (5\bar{h}_{0-5} - 4\bar{h}_{0-4})(\Delta L \times w)(T_s - T_\infty)$$

Hence, with $x_5 = 5\Delta L = 0.05 \text{ m}$ and $x_4 = 4\Delta L = 0.04 \text{ m}$, it follows that $\bar{h}_{0-5} = 24.1 \text{ W/m}^2 \cdot \text{K}$ and $\bar{h}_{0-4} = 26.9 \text{ W/m}^2 \cdot \text{K}$ and

$$q_5 = (5 \times 24.1 - 4 \times 26.9) \text{ W/m}^2 \cdot \text{K} (0.01 \times 0.2) \text{ m}^2 (500 - 25) \text{ K} = 12.2 \text{ W} \quad <$$

Similarly, where $\bar{h}_{0-10} = 17.00 \text{ W/m}^2 \cdot \text{K}$ and $\bar{h}_{0-9} = 17.92 \text{ W/m}^2 \cdot \text{K}$,

$$q_{10} = (10\bar{h}_{0-10} - 9\bar{h}_{0-9})(\Delta L \times w)(T_s - T_\infty)$$

$$q_{10} = (10 \times 17.00 - 9 \times 17.92) \text{ W/m}^2 \cdot \text{K} (0.01 \times 0.2) \text{ m}^2 (500 - 25) \text{ K} = 8.3 \text{ W} \quad <$$

Continued...

PROBLEM 7.9 (Cont.)

For the entire heater,

$$\bar{h}_{0-25} = \frac{k}{L} 0.664 \text{Re}_L^{1/2} \text{Pr}^{1/3} = \frac{0.0429}{0.25} \times 0.664 \left(\frac{2 \times 0.25}{43.54 \times 10^{-6}} \right)^{1/2} (0.683)^{1/3} = 10.75 \text{ W/m}^2 \cdot \text{K}$$

and the heat rate over all 25 strips is

$$q_{0-25} = \bar{h}_{0-25} (L \times w) (T_s - T_\infty) = 10.75 \text{ W/m}^2 \cdot \text{K} (0.25 \times 0.2) \text{ m}^2 (500 - 25)^\circ \text{C} = 255.3 \text{ W} <$$

(b,c) Using the *IHT Correlations Tool, External Flow, for Laminar or Mixed Flow Conditions*, and following the same method of solution as above, the heat rates for the first, fifth, tenth and all the strips were calculated for air velocities of 2, 5 and 10 m/s. To evaluate the heat rates for fully turbulent conditions, the analysis was performed setting $\text{Re}_{x,c} = 1 \times 10^6$. The results are tabulated below.

Flow conditions	u_∞ (m/s)	q_1 (W)	q_5 (W)	q_{10} (W)	q_{0-25} (W)
Laminar	2	51.1	12.1	8.3	256
	5	80.9	19.1	13.1	404
	10	114	27.0	18.6	572
Fully turbulent	2	17.9	10.6	9.1	235
	5	37.3	22.1	19.0	490
	10	64.9	38.5	33.1	853

COMMENTS: (1) An alternative approach to evaluating the heat loss from a single strip, for example, strip 5, would take the form $q_5 = \bar{h}_5 (\Delta L \times w) (T_s - T_\infty)$, where $h_5 \approx h_{x=4.5\Delta L}$ or $\bar{h}_5 \approx (h_{x=5\Delta L} + h_{x=4\Delta L})/2$.

(2) From the tabulated results, note that for both flow conditions, the heat rate for each strip and the entire heater, increases with increasing air velocity. For both flow conditions and for any specified velocity, the strip heat rates decrease with increasing distance from the leading edge.

(3) To more fully appreciate the effects due to laminar vs. turbulent flow conditions and air velocity, it is useful to examine the local coefficient as a function of distance from the leading edge. How would you use the results plotted below to explain heat rate behavior evident in the summary table above?

PROBLEM 7.10

KNOWN: Speed and temperature of atmospheric air flowing over a flat plate of prescribed length and temperature.

FIND: Rate of heat transfer corresponding to $Re_{x,c} = 10^5$, 5×10^5 and 10^6 .

SCHEMATIC:

ASSUMPTIONS: (1) Flow over top and bottom surfaces.

PROPERTIES: Table A-4, Air ($T_f = 348\text{K}$, 1 atm): $\rho = 1.00\text{ kg/m}^3$, $\nu = 20.72 \times 10^{-6}\text{ m}^2/\text{s}$, $k = 0.0299\text{ W/m}\cdot\text{K}$, $Pr = 0.700$.

ANALYSIS: With

$$Re_L = \frac{u_\infty L}{\nu} = \frac{25\text{ m/s} \times 1\text{ m}}{20.72 \times 10^{-6}\text{ m}^2/\text{s}} = 1.21 \times 10^6$$

the flow becomes turbulent for each of the three values of $Re_{x,c}$. Hence,

$$\overline{Nu}_L = \left(0.037 Re_L^{4/5} - A \right) Pr^{1/3}$$

$$A = 0.037 Re_{x,c}^{4/5} - 0.664 Re_{x,c}^{1/2}$$

$Re_{x,c}$	10^5	5×10^5	10^6
A	160	871	1671
\overline{Nu}_L	2267	1635	926
$\bar{h}_L \left(\text{W/m}^2 \cdot \text{K} \right)$	67.8	48.9	27.7
$q' \left(\text{W/m} \right)$	13,560	9780	5530

where $q' = 2 \bar{h}_L L (T_s - T_\infty)$ is the total heat loss per unit width of plate.

COMMENTS: Note that \bar{h}_L decreases with increasing $Re_{x,c}$, as more of the surface becomes covered with a laminar boundary layer.

PROBLEM 7.11

KNOWN: Dimensions and surface temperatures of a flat plate. Velocity and temperature of air and water flow parallel to the plate.

FIND: (a) Average convective heat transfer coefficient, convective heat transfer rate, and drag force when $L = 2$ m, $w = 2$ m. (b) Average convective heat transfer coefficient, convective heat transfer rate, and drag force when $L = 0.1$ m, $w = 0.1$ m.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Boundary layer assumptions are valid, (3) Constant properties, (4) Transition Reynolds number is 5×10^5 .

PROPERTIES: Using *IHT*, Air ($p = 1$ atm, $T_f = 35^\circ\text{C} = 308$ K): $\text{Pr} = 0.706$, $k = 26.9 \times 10^{-3}$ W/m-K, $\nu = 1.669 \times 10^{-5}$ m²/s, $\rho = 1.135$ kg/m³. Air ($p = 1$ atm, $T_f = 50^\circ\text{C} = 323$ K): $\text{Pr} = 0.704$, $k = 28.0 \times 10^{-3}$ W/m-K, $\nu = 1.82 \times 10^{-5}$ m²/s, $\rho = 1.085$ kg/m³. Water ($T_f = 308$ K): $\text{Pr} = 4.85$, $k = 0.625$ W/m-K, $\nu = 7.291 \times 10^{-7}$ m²/s, $\rho = 994$ kg/m³. Water ($T_f = 323$ K): $\text{Pr} = 3.56$, $k = 0.643$ W/m-K, $\nu = 5.543 \times 10^{-7}$ m²/s, $\rho = 988$ kg/m³.

ANALYSIS:

(a) We begin by calculating the Reynolds numbers for the two different surface temperatures:

$$\begin{aligned} \text{Re}_{i1} &= \frac{u_{x1} L}{\nu_1} = \frac{5 \text{ m/s} \times 2 \text{ m}}{1.669 \times 10^{-5} \text{ m}^2/\text{s}} = 5.99 \times 10^5 \\ \text{Re}_{i2} &= \frac{u_{x2} L}{\nu_2} = \frac{5 \text{ m/s} \times 2 \text{ m}}{1.82 \times 10^{-5} \text{ m}^2/\text{s}} = 5.49 \times 10^5 \end{aligned}$$

Therefore, in both cases the flow is turbulent at the end of the plate and the conditions in the boundary layer are "mixed."

The average drag coefficient can be calculated from Equation 7.40. For the first case,

$$\begin{aligned}\bar{C}_{fL1} &= 0.074 \text{Re}_{L1}^{-1/5} - 1742 \text{Re}_{L1}^{-1} \\ &= 0.074(5.99 \times 10^5)^{-1/5} - 1742(5.99 \times 10^5)^{-1} = 2.27 \times 10^{-3}\end{aligned}$$

Then

$$\begin{aligned} F_{D1} &= \bar{C}_{fL1} \frac{1}{2} \rho u_{\infty}^2 A_s \\ &= 2.27 \times 10^{-3} \times \frac{1}{2} \times 1.135 \text{ kg/m}^3 \times (5 \text{ m/s})^2 \times 8 \text{ m}^2 = 0.257 \text{ N} \\ &= 0.257 \text{ N} \end{aligned}$$

 \angle

Continued...

PROBLEM 7.11 (Cont.)

The average Nusselt number is calculated from Equation 7.38, with $A = 871$ for a transition Reynolds number of 5×10^5 .

$$\begin{aligned}\overline{Nu}_{L1} &= (0.037 Re_L^{4/5} - 871) Pr^{1/3} \\ &= [0.037(5.99 \times 10^5)^{4/5} - 871](0.706)^{1/3} = 604.\end{aligned}$$

Then

$$\overline{h}_{L1} = \overline{Nu}_{L1}k/L = 604 \times 26.9 \times 10^{-3} \text{ W/m} \cdot \text{K} / 2 \text{ m} = 8.13 \text{ W/m}^2 \cdot \text{K} \quad <$$

and

$$q_1 = \overline{h}_{L1}A_s(T_s - T_\infty) = 8.13 \text{ W/m}^2 \cdot \text{K} \times 8 \text{ m}^2 \times (50^\circ\text{C} - 20^\circ\text{C}) = 1950 \text{ W} \quad <$$

Similarly for $T_s = 80^\circ\text{C}$ we find

$$F_{D2} = 0.227 \text{ N}, \quad \overline{h}_{L2} = 7.16 \text{ W/m}^2 \cdot \text{K}, \quad q_2 = 3440 \text{ W}$$

<

(b) Repeating the calculations for water

$$Re_{L1} = \frac{u_\infty L}{\nu} = \frac{5 \text{ m/s} \times 0.1 \text{ m}}{7.291 \times 10^{-7} \text{ m}^2/\text{s}} = 6.86 \times 10^5$$

$$Re_{L2} = 9.02 \times 10^5$$

The flow is turbulent at the end of the plate in both cases.

$$\overline{C}_{fL1} = 0.074(6.86 \times 10^5)^{-1/5} - 1742(6.86 \times 10^5)^{-1} = 2.49 \times 10^{-3}$$

$$F_{D1} = 2.49 \times 10^{-3} \times 1/2 \times 994 \text{ kg/m}^3 \times (5 \text{ m/s})^2 \times 0.02 \text{ m}^2 = 0.620 \text{ N} \quad <$$

$$\overline{Nu}_L = [0.037(6.86 \times 10^5)^{4/5} - 871](4.85)^{1/3} = 1450$$

$$\overline{h}_{L1} = 1450 \times 0.625 \text{ W/m} \cdot \text{K} / 0.1 \text{ m} = 9050 \text{ W/m}^2 \cdot \text{K} \quad <$$

$$q_1 = 9050 \text{ W/m}^2 \cdot \text{K} \times 0.02 \text{ m}^2 \times (50^\circ\text{C} - 20^\circ\text{C}) = 5430 \text{ W} \quad <$$

For the higher surface temperature,

$$F_{D2} = 0.700 \text{ N}, \quad \overline{h}_{L2} = 12,600 \text{ W/m}^2 \cdot \text{K}, \quad q_2 = 15,100 \text{ W} \quad <$$

COMMENTS: (1) For air, kinematic viscosity increases with increasing temperature. This decreases the Reynolds number which causes the transition to turbulence to move downstream, thereby decreasing the drag force and average heat transfer coefficient. The heat transfer rate increases for the higher surface temperature, however, because of the greater temperature difference between the surface and air. (2) For water, kinematic viscosity decreases with increasing temperature, causing the opposite trends as for air. The heat transfer rate increases dramatically for the higher surface temperature because of the increases in both the heat transfer coefficient and temperature difference. (3) Even though the water flows over a plate that is 400 times smaller, the drag force and heat transfer rate are larger than for air because of the smaller viscosity and greater density, thermal conductivity, and Prandtl number. The discrepancy is particularly great for the heat transfer rate. (4) The problem highlights the importance of carefully accounting for the temperature dependence of thermal properties.

PROBLEM 7.12

KNOWN: Velocity and temperature of water in parallel flow over a flat plate of 1-m length.

FIND: (a) Calculate and plot the variation of the local convection coefficient, $h_x(x)$, with distance for flow conditions corresponding to transition Reynolds numbers of 5×10^5 , 3×10^5 and 0 (fully turbulent), (b) Plot the variation of the average convection coefficient, $\bar{h}_x(x)$, for the three flow conditions of part (a), and (c) Determine the average convection coefficients for the entire plate, \bar{h}_L , for the three flow conditions of part (a).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant surface temperature, and (3) Critical Reynolds depends upon prescribed flow conditions.

PROPERTIES: Table A.6, Water (300 K): $\rho = 997 \text{ kg/m}^3$, $\mu = 855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$, $\nu = \mu/\rho = 0.858 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.613 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 583$.

ANALYSIS: (a) The Reynolds number for the plate ($L = 1 \text{ m}$) is

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{2 \text{ m/s} \times 1 \text{ m}}{0.858 \times 10^{-6} \text{ m}^2/\text{s}} = 2.33 \times 10^6.$$

and the boundary layer is mixed with $\text{Re}_{x,c} = 5 \times 10^5$,

$$x_c = L (\text{Re}_{x,c} / \text{Re}_L) = 1 \text{ m} \frac{5 \times 10^5}{2.33 \times 10^6} = 0.215 \text{ m}$$

Using the *IHT Correlation Tool, External Flow, Local coefficients for Laminar or Turbulent Flow*, $h_x(x)$ was evaluated and plotted with critical Reynolds numbers of 5×10^5 , 3.0×10^5 and 0 (fully turbulent). Note the location of the laminar-turbulent transition for the first two flow conditions.

Continued...

PROBLEM 7.12 (Cont.)

(b) Using the *IHT Correlation Tool, External Flow, Average coefficient for Laminar or Mixed Flow*, $\bar{h}_x(x)$ was evaluated and plotted for the three flow conditions. Note that the change in $\bar{h}_x(x)$ at the critical length, x_c , is rather gradual, compared to the abrupt change for the local coefficient, $h_x(x)$.

(c) The average convection coefficients for the plate can be determined from the above plot since $\bar{h}_L = \bar{h}_x(L)$. The values for the three flow conditions are

$$\bar{h}_L = 4110, 4490 \text{ and } 5072 \text{ W/m}^2 \cdot \text{K}$$

COMMENTS: A copy of the *IHT Workspace* used to generate the above plot is shown below.

/ Method of Solution:* Use the Correlation Tools, External Flow, Flat Plate, for (i) Local, laminar or turbulent flow and (ii) Average, laminar or mixed flow, to evaluate the local and average convection coefficients as a function of position on the plate. In each of these tools, the value of the critical Reynolds number, Re_{xc} , can be set corresponding to the special flow conditions. **/*

// Correlation Tool: External Flow, Plate Plate, Local, laminar or turbulent flow.

$Nu_x = Nu_{x,EF,FP,LT}(Re_x, Re_{xc}, Pr)$ *// Eq 7.23,36*

$Nu_x = h_x * x / k$

$Re_x = u_{inf} * x / \nu$

$Re_{xc} = 1e-10$

// Evaluate properties at the film temperature, Tf.

PROBLEM 7.13

KNOWN: Two plates of length L and $2L$ experience parallel flow with a critical Reynolds number of 5×10^5 .

FIND: Reynolds numbers for which the total heat transfer rate is independent of orientation.

SCHEMATIC:

ASSUMPTIONS: (1) Plate temperatures and flow conditions are equivalent.

ANALYSIS: The total heat transfer rate would be the same ($q_L = q_{2L}$), if the convection coefficients were equal, $\bar{h}_L = \bar{h}_{2L}$. Conditions for which such an equality is possible may be inferred from a sketch of \bar{h}_L versus Re_L .

For laminar flow ($Re_L < Re_{x,c}$), $\bar{h}_L \propto L^{-1/2}$, and for mixed laminar and turbulent flow ($Re_L > Re_{x,c}$), $\bar{h}_L = C_1 L^{-1/5} - C_2 L^{-1}$. Hence \bar{h}_L varies with Re_L as shown, and two possibilities are suggested.

Case (a): Laminar flow exists on the shorter plate, while mixed flow conditions exist on the longer plate.

Case (b): Mixed boundary layer conditions exist on both plates.

In both cases, it is required that

$$\bar{h}_L = \bar{h}_{2L} \quad \text{and} \quad Re_{2L} = 2 Re_L.$$

Continued

PROBLEM 7.13 (Cont.)

Case (a): From expressions for \bar{h}_L in laminar and mixed flow

$$0.664 \frac{k}{L} \text{Re}_L^{1/2} \text{Pr}^{1/3} = \frac{k}{2L} (0.037 \text{Re}_{2L}^{4/5} - 871) \text{Pr}^{1/3}$$

$$0.664 \text{Re}_L^{1/2} = 0.032 \text{Re}_L^{4/5} - 435.$$

Since $\text{Re}_L < 5 \times 10^5$ and $\text{Re}_{2L} = 2 \text{Re}_L > 5 \times 10^5$, the required value of Re_L may be narrowed to the range

$$2.5 \times 10^5 < \text{Re}_L < 5 \times 10^5.$$

From a trial-and-error solution, it follows that

$$\text{Re}_L \approx 3.2 \times 10^5. \quad <$$

Case (b): For mixed flow on both plates

$$\frac{k}{L} (0.037 \text{Re}_L^{4/5} - 871) \text{Pr}^{1/3} = \frac{k}{2L} (0.037 \text{Re}_{2L}^{4/5} - 871) \text{Pr}^{1/3}$$

or

$$0.037 \text{Re}_L^{4/5} - 871 = 0.032 \text{Re}_L^{4/5} - 435$$

$$0.005 \text{Re}_L^{4/5} = 436$$

$$\text{Re}_L \approx 1.50 \times 10^6. \quad <$$

COMMENTS: (1) Note that it is impossible to satisfy the requirement that $\bar{h}_L = \bar{h}_{2L}$ if $\text{Re}_L < 0.25 \times 10^5$ (laminar flow for both plates).

(2) The results are independent of the nature of the fluid.

PROBLEM 7.14

KNOWN: Dimensions of and heat generation rate in thin membrane. Velocity and temperature of air flow parallel to membrane. Air streams above and below membrane are in same, opposite, or orthogonal directions.

FIND: (a) Minimum and maximum local membrane temperatures. Flow configuration that minimizes the membrane temperature. (b) Plot the surface temperature distribution for flow in the same and opposite directions. Find configuration that minimizes spatial temperature gradients.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Boundary layer assumptions hold, (3) Constant properties, (4) Solutions are bounded by constant surface temperature and constant heat flux cases for the opposite and orthogonal flow configurations.

PROPERTIES: Table A-4, Air ($T_f \approx 323 \text{ K}$): $\nu = 18.20 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0280 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.704$.

ANALYSIS:

(a) We begin by calculating the Reynolds number

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{2 \text{ m/s} \times 0.15 \text{ m}}{18.20 \times 10^{-6} \text{ m}^2/\text{s}} = 1.65 \times 10^4$$

Therefore flow is laminar.

(a) Top and bottom flows in same direction.

By symmetry, the heat flux from the membrane to the air is 50 W/m^2 everywhere for the top and bottom air flows. Since the heat flux is uniform, the local Nusselt number is given by Equation 7.45,

$$\text{Nu}_x = 0.453 \text{ Re}_x^{1/2} \text{ Pr}^{1/3}$$

Thus $h_x = c_q x^{-1/2}$
where

$$\begin{aligned} c_q &= 0.453(u_\infty/\nu)^{1/2} \text{ Pr}^{1/3} k \\ &= 0.453(2 \text{ m/s}/18.2 \times 10^{-6} \text{ m}^2/\text{s})^{1/2} \times (0.704)^{1/3} \times 0.028 \text{ W/m}\cdot\text{K} = 3.74 \text{ W/m}^{3/2} \cdot \text{K} \end{aligned}$$

$$\text{Then } q_s'' = h_x(T_s - T_\infty) \text{ and } T_s - T_\infty = \frac{q_s''}{h_x} = \frac{q_s''}{c_q} x^{1/2} \quad (1)$$

Continued....

PROBLEM 7.14 (Cont.)

Clearly the minimum temperature occurs at $x = 0$ and is

$$T_{\min} = T_{\infty} = 25^{\circ}\text{C} \quad <$$

The maximum temperature occurs at $x = L$ and is

$$T_{\max} = 25^{\circ}\text{C} + 50 \text{ W/m}^2 \times (0.15 \text{ m})^{1/2} / 3.74 \text{ W/m}^{3/2} \cdot \text{K} = 30.2^{\circ}\text{C} \quad <$$

(ii) Top and bottom flows in opposite direction.

The heat flux entering each of the top and bottom flows will no longer be uniform. Near $x = 0$, where the top flow first encounters the plate, the heat transfer coefficient on the top surface is theoretically infinite, and all the generated heat will enter the top flow. The opposite situation will occur at $x = L$.

We bound the solution by considering Nusselt number correlations for uniform surface temperature and uniform surface heat flux, Equations 7.23 and 7.45. In both cases, the heat transfer coefficient varies as $x^{-1/2}$, where x is the distance from the leading edge, thus for the top and bottom,

$$h_{x,t} = cx^{-1/2}, \quad h_{x,b} = c(L - x)^{-1/2}$$

And all of the generated heat is removed by the top and bottom flows:

$$\dot{q}'' = (h_{x,t} + h_{x,b})(T_s - T_{\infty})$$

$$\text{Thus} \quad T_s - T_{\infty} = \frac{\dot{q}''}{h_{x,t} + h_{x,b}} = \frac{\dot{q}''}{c[x^{-1/2} + (L - x)^{-1/2}]} \quad (2)$$

The minimum temperature occurs at $x = 0$ or $x = L$, and is

$$T_{\min} = T_{\infty} = 25^{\circ}\text{C} \quad <$$

The maximum temperature occurs where the denominator is minimum:

$$\frac{d}{dx} [x^{-1/2} + (L - x)^{-1/2}] = 0$$

$$-\frac{1}{2}x^{-3/2} + \frac{1}{2}(L - x)^{-3/2} = 0$$

$$x = L - x$$

$$x = L/2$$

At that location

$$T_{\max} = T_{\infty} + \frac{\dot{q}''}{c2(L/2)^{-1/2}}$$

For uniform surface temperature,

$$c_T = 0.332(u_{\infty}/\nu)^{1/2} \text{Pr}^{1/3} \text{ k}$$

$$= 0.332(2 \text{ m/s}/18.2 \times 10^{-6} \text{ m}^2/\text{s})^{1/2} \times (0.704)^{1/3} \times 0.0280 \text{ W/m} \cdot \text{K} = 2.74 \text{ W/m}^{3/2} \cdot \text{K}$$

$$\text{And} \quad T_{\max} = 25^{\circ}\text{C} + \frac{100 \text{ W/m}^2}{2.74 \text{ W/m}^{3/2} \cdot \text{K} \times 2 \times (0.15 \text{ m}/2)^{-1/2}} = 30.0^{\circ}\text{C}$$

Continued....

PROBLEM 7.14 (Cont.)

For uniform surface heat flux, we previously found $c_q = 3.74 \text{ W/m}^{3/2}\cdot\text{K}$, thus, $T_{\max} = 28.7^\circ\text{C}$.

Therefore, for the opposite flow case, $28.7^\circ\text{C} \leq T_{\max} \leq 30.0^\circ\text{C}$

(iii) Top and bottom flows in orthogonal directions.

Here the heat transfer coefficients are given by

$$h_{x,t} = cx^{-1/2}, \quad h_{y,b} = cy^{-1/2}$$

And $\dot{q}'' = c(x^{-1/2} + y^{-1/2})(T_s - T_\infty)$

So $T_s - T_\infty = \frac{\dot{q}''}{c(x^{-1/2} + y^{-1/2})}$

The temperature will be minimum along $x = 0$ or $y = 0$, where

$$T_{\min} = T_\infty = 25^\circ\text{C}$$

The temperature will be maximum along $x = y = L$, where

$$T_{\max} = T_\infty + \frac{\dot{q}''}{c \cdot 2 L^{-1/2}}$$

The values of c are the same as previously, therefore we find $30.2^\circ\text{C} \leq T_{\max} \leq 32.1^\circ\text{C}$

The surface temperature is minimized when the air streams are in opposite directions, because a small heat transfer coefficient on the top is paired with a large heat transfer coefficient on the bottom, and vice versa.

(b) *IHT* was used to plot Equation (1) and (2) for $c = c_T$ or c_q . The result is shown below.

The spatial temperature gradients are somewhat less for the opposite flow case.

COMMENTS: To correctly treat the convective heat transfer would require a coupled numerical solution of the thermal energy equation for both boundary layers simultaneously.

PROBLEM 7.15

KNOWN: Temperature, pressure and Reynolds number for air flow over a flat plate of uniform surface temperature.

FIND: (a) Rate of heat transfer from the plate, (b) Rate of heat transfer if air velocity is doubled and pressure is increased to 10 atm.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation, (4) $Re_{x_c} = 5 \times 10^5$.

PROPERTIES: Table A-4, Air ($T_f = 348\text{K}$, 1 atm): $k = 0.0299 \text{ W/m}\cdot\text{K}$, $Pr = 0.70$.

ANALYSIS: (a) The heat rate is

$$q = \bar{h}_L (w \times L) (T_s - T_{\infty}).$$

Since the flow is laminar over the entire plate for $Re_L = 4 \times 10^4$, it follows that

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = 0.664 Re_L^{1/2} Pr^{1/3} = 0.664 (40,000)^{1/2} (0.70)^{1/3} = 117.9.$$

Hence
$$\bar{h}_L = 117.9 \frac{k}{L} = 117.9 \frac{0.0299 \text{ W/m}\cdot\text{K}}{0.2 \text{ m}} = 17.6 \text{ W/m}^2 \cdot \text{K}$$

and
$$q = 17.6 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (0.1 \text{ m} \times 0.2 \text{ m}) (100 - 50)^{\circ}\text{C} = 17.6 \text{ W.} \quad <$$

(b) With $p_2 = 10 p_1$, it follows that $\rho_2 = 10 \rho_1$ and $v_2 = v_1/10$. Hence

$$Re_{L,2} = \left(\frac{u_{\infty} L}{\nu} \right)_2 = 2 \times 10 \left(\frac{u_{\infty} L}{\nu} \right)_1 = 20 Re_{L,1} = 8 \times 10^5$$

and mixed boundary layer conditions exist on the plate. Hence

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = \left(0.037 Re_L^{4/5} - 871 \right) Pr^{1/3} = \left[0.037 \times (8 \times 10^5)^{4/5} - 871 \right] (0.70)^{1/3}$$

$$\overline{Nu}_L = 961.$$

Hence,
$$\bar{h}_L = 961 \frac{0.0299 \text{ W/m}\cdot\text{K}}{0.2 \text{ m}} = 143.6 \text{ W/m}^2 \cdot \text{K}$$

$$q = 143.6 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (0.1 \text{ m} \times 0.2 \text{ m}) (100 - 50)^{\circ}\text{C} = 143.6 \text{ W.} \quad <$$

COMMENTS: Note that, in calculating $Re_{L,2}$, ideal gas behavior has been assumed. It has also been assumed that k , μ and Pr are independent of pressure over the range considered.

PROBLEM 7.16

KNOWN: Length and surface temperature of a rectangular fin.

FIND: (a) Heat removal per unit width, q' , when air at a prescribed temperature and velocity is in parallel, turbulent flow over the fin, and (b) Calculate and plot q' for motorcycle speeds ranging from 10 to 100 km/h.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Turbulent flow over entire surface.

PROPERTIES: Table A.4, Air (412 K, 1 atm): $\nu = 27.85 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0346 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.69$.

ANALYSIS: (a) The heat loss per unit width is

$$q' = 2 \times [\bar{h}_L L (T_s - T_\infty)]$$

where \bar{h} is obtained from the correlation, Eq. 7.38 but with turbulent flow over the entire surface,

$$\overline{\text{Nu}}_L = 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} = 0.037 \left[\frac{80 \text{ km/h} \times 1000 \text{ m/km} \times 1/3600 \text{ h/s} \times 0.15 \text{ m}}{27.85 \times 10^{-6} \text{ m}^2/\text{s}} \right]^{4/5} (0.69)^{1/3} = 378$$

Hence,

$$\bar{h}_L = \frac{k}{L} \overline{\text{Nu}}_L = \frac{0.0346 \text{ W/m}\cdot\text{K}}{0.15 \text{ m}} 378 = 87 \text{ W/m}^2 \cdot \text{K}$$

$$q' = 2 \times [87 \text{ W/m}^2 \cdot \text{K} \times 0.15 \text{ m} (523 - 300) \text{ K}] = 5826 \text{ W/m}.$$

<

(b) Using the foregoing equations in the IHT Workspace, q' as a function of speed was calculated and is plotted as shown.

COMMENTS: (1) Radiation emission from the fin is not negligible. With an assumed emissivity of $\epsilon = 1$, the rate of emission per unit width at 80 km/h would be $q' = (\sigma T_s^4) 2L = 1273 \text{ W/m}$. If the fin received negligible radiation from its surroundings, its loss by radiation would then be approximately 20% of that by convection.

(2) From the correlation and heat rate expression, it follows that $q' \sim u_\infty^{4/5}$. That is, q' vs. u_∞ is nearly linear as evident from the above plot.

PROBLEM 7.17

KNOWN: Wall of a metal building experiences a 10 mph (4.47 m/s) breeze with air temperature of 90°F (32.2°C) and solar insolation of 400 W/m². The length of the wall in the wind direction is 10 m and the emissivity is 0.93.

FIND: Estimate the average wall temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) The solar absorptivity of the wall is unity, (3) Sky irradiation is negligible, (4) Wall is isothermal at the average temperature T_s , (5) Flow is fully turbulent over the wall, and (6) Negligible heat transfer into the building.

PROPERTIES: Table A-4, Air (assume $T_f = 305$ K, 1 atm): $\nu = 16.27 \times 10^{-6}$ m²/s, $k = 0.02658$ W/m·K, $Pr = 0.707$.

ANALYSIS: Perform an energy balance on the wall surface considering convection, absorbed irradiation and emission. On a per unit width basis,

$$\begin{aligned} \dot{E}'_{in} - \dot{E}'_{out} &= 0 \\ -q'_{cv} + (\alpha_S G_S - E_s) L &= 0 \\ -\bar{h}_L L (T_s - T_\infty) + (\alpha_S G_S - \epsilon \sigma T_s^4) L &= 0 \end{aligned} \quad (1)$$

The average convection coefficient is estimated using Eq. 7.41 assuming fully turbulent flow over the length of the wall in the direction of the breeze.

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = 0.037 Re_L^{4/5} Pr^{1/3} \quad (2)$$

$$Re_L = u_\infty L / \nu = 4.47 \text{ m/s} \times 10 \text{ m} / 16.27 \times 10^{-6} \text{ m}^2/\text{s} = 2.748 \times 10^6$$

$$\bar{h}_L = (0.02658 \text{ W/m} \cdot \text{K} / 10 \text{ m}) \times 0.037 (2.748 \times 10^6)^{4/5} (0.707)^{1/3} = 12.4 \text{ W/m}^2 \cdot \text{K}$$

Substituting numerical values into Eq. (1), find T_s .

$$\begin{aligned} -12.4 \text{ W/m}^2 \times 10 \text{ m} [T_s - (32.2 + 273)] \text{ K} \\ + [1.0 \times 400 \text{ W/m}^2 - 0.93 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 T_s^4] \times 10 \text{ m} = 0 \end{aligned}$$

$$T_s = 302.2 \text{ K} = 29^\circ\text{C}$$

<

COMMENTS: (1) The properties for the correlation should be evaluated at $T_f = (T_s + T_\infty)/2 = 304$ K. The assumption of 305 K was reasonable.

(2) Is the heat transfer by the emission process significant? Would application of a low emissive coating be effective in reducing the wall temperature, assuming α_S remained unchanged? Or, should a low solar absorbing coating be considered?

PROBLEM 7.18

KNOWN: Solar cell material dimensions and properties, solar-to-electrical conversion efficiency dependence on silicon temperature, solar irradiation and location where the irradiation is absorbed, air velocity and temperature.

FIND: (a) Electrical power produced and silicon temperature for a $L = 1$ m long, $w = 0.1$ m wide solar cell with $G = 700$ W/m² with tripped boundary layer, (b) Same as Part (a) but with $L = 0.1$ m, $w = 1$ m, (c) Plot of the electrical power produced and the silicon temperature for air velocities in the range $0 \leq u_{\infty} \leq 10$ m/s for the $L = 0.1$ m configuration.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Tripped and turbulent boundary layer, (5) Large surroundings, (6) Negligible contact resistances.

PROPERTIES: Table A.4, air (assume $T_f = 308$ K, $p = 1$ atm): $k = 0.0269$ W/m·K, $\nu = 1.669 \times 10^{-5}$ m²/s, $Pr = 0.706$.

ANALYSIS:

(a) We begin by drawing the thermal circuit for the problem, recognizing that there is no heat transfer downward from the thin silicon layer.

Continued....

PROBLEM 7.18 (Cont.)

The thermal resistances are

$$R_{t,g} = L_g/k_g A = 3 \times 10^{-3} \text{ m} / (1.4 \text{ W/m} \cdot \text{K} \times 1 \text{ m} \times 0.1 \text{ m}) = 21.43 \times 10^{-3} \text{ K/W}$$

$$R_{t,a} = L_a/k_a A = 0.1 \times 10^{-3} \text{ m} / (145 \text{ W/m} \cdot \text{K} \times 1 \text{ m} \times 0.1 \text{ m}) = 6.897 \times 10^{-6} \text{ K/W}$$

$$h_{\text{rad}} = \varepsilon_g \sigma (T_1 + T_{\text{sur}})(T_1^2 + T_{\text{sur}}^2)$$

$$R_{t,\text{rad}} = \frac{1}{0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T_1 + 298 \text{ K}) \times (T_1^2 + (298 \text{ K})^2) \times 1 \text{ m} \times 0.1 \text{ m}} \quad (1)$$

For the tripped boundary layer,

$$\text{Re}_L = \frac{u_m L}{\nu} = \frac{4 \text{ m/s} \times 1 \text{ m}}{1.669 \times 10^{-5} \text{ m}^2/\text{s}} = 239.7 \times 10^3$$

From Equation 7.38

$$\overline{\text{Nu}}_L = 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} = 0.037 \times [239.7 \times 10^3]^{0.8} \times 0.706^{1/3} = 662.8$$

$$\bar{h} = \overline{\text{Nu}}_L k / L = 662.8 \times 0.0269 \text{ W/m} \cdot \text{K} / 1 \text{ m} = 17.82 \text{ W/m}^2 \cdot \text{K}$$

$$R_{t,\text{conv}} = 1/\bar{h}A = \frac{1}{17.82 \text{ W/m}^2 \cdot \text{K} \times 1 \text{ m} \times 0.1 \text{ m}} = 561.2 \times 10^{-3} \text{ K/W}$$

From the thermal circuit,

$$0.83GA(1 - \eta) = (T_3 - T_1)/(R_{t,g} + R_{t,a}) \quad \text{or} \quad T_3 - T_1 = (R_{t,g} + R_{t,a}) 0.83GA(1 - \eta)$$

$$T_3 - T_1 = (21.43 \times 10^{-3} \text{ K/W} + 6.897 \times 10^{-6} \text{ K/W}) \times 0.83 \times 700 \text{ W/m}^2 \times 1 \text{ m} \times 0.1 \text{ m} \times (1 - \eta)$$

$$T_3 - T_1 = 1.245(1 - \eta) \quad (2)$$

We also note from the thermal circuit,

Continued...

PROBLEM 7.18 (Cont.)

$$0.83GA(1 - \eta) + 0.1G = (T_1 - T_{\text{sur}})/R_{t,\text{rad}} + (T_1 - T_{\infty})/R_{t,\text{conv}}$$

Since $T_{\infty} = T_{\text{sur}}$

$$0.83GA(1 - \eta) + 0.1G = (T_1 - T_{\text{sur}}) \left[\frac{1}{R_{t,\text{rad}}} + \frac{1}{R_{t,\text{conv}}} \right]$$

$$T_1 - T_{\text{sur}} = \frac{0.83GA(1 - \eta) + 0.1GA}{\left[\frac{1}{R_{t,\text{rad}}} + \frac{1}{R_{t,\text{conv}}} \right]}$$

$$T_1 - T_{\text{sur}} = \frac{0.83 \times 700 \text{ W/m}^2 \times 1 \text{ m} \times 0.1 \text{ m} \times (1 - \eta) + 0.1 \times 700 \text{ W/m}^2 \times 1 \text{ m} \times 0.1 \text{ m}}{\left[\frac{1}{R_{t,\text{rad}}} + 1.7819 \text{ W/K} \right]}$$

$$T_1 - T_{\text{sur}} = \frac{58.1 \text{ W} (1 - \eta) + 7 \text{ W}}{\left[\frac{1}{R_{t,\text{rad}}} + 1.7819 \text{ W/K} \right]} \quad (3)$$

$$\text{where } \eta = 0.28 - 0.001^\circ\text{C}^{-1} \times (T_3 - 273)^\circ\text{C} \quad (4)$$

Equations (1) – (4) may be solved simultaneously to yield

$$\eta = 0.2324, T_3 = T_{\text{si}} = 47.6^\circ\text{C}, T_1 = 46.6^\circ\text{C}, R_{t,\text{rad}} = 1.661 \text{ K/W} \quad <$$

$$\text{The electric power is } P = 0.83GA\eta = 0.83 \times 700 \text{ W/m}^2 \times 1 \text{ m} \times 0.1 \text{ m} \times 0.2324 = 13.50 \text{ W} \quad <$$

(b) For the tripped boundary layer

$$\text{Re}_L = \frac{u_m L}{\nu} = \frac{4 \text{ m/s} \times 0.1 \text{ m}}{1.669 \times 10^{-5} \text{ m}^2/\text{s}} = 239.7 \times 10^2$$

From Equation 7.38

$$\overline{\text{Nu}}_L = 0.037 \text{Re}^{4/5} \text{Pr}^{1/3} = 0.037 \times [239.7 \times 10^2]^{0.8} \times 0.706^{1/3} = 105$$

$$\bar{h} = \overline{\text{Nu}}_L k/L = 105 \times 0.0269 \text{ W/m} \cdot \text{K} / 0.1 \text{ m} = 28.25 \text{ W/m}^2 \cdot \text{K}$$

$$R_{t,\text{conv}} = 1/\bar{h}A = \frac{1}{28.25 \text{ W/m}^2 \cdot \text{K} \times 1 \text{ m} \times 0.1 \text{ m}} = 354.0 \times 10^{-3} \text{ K/W}$$

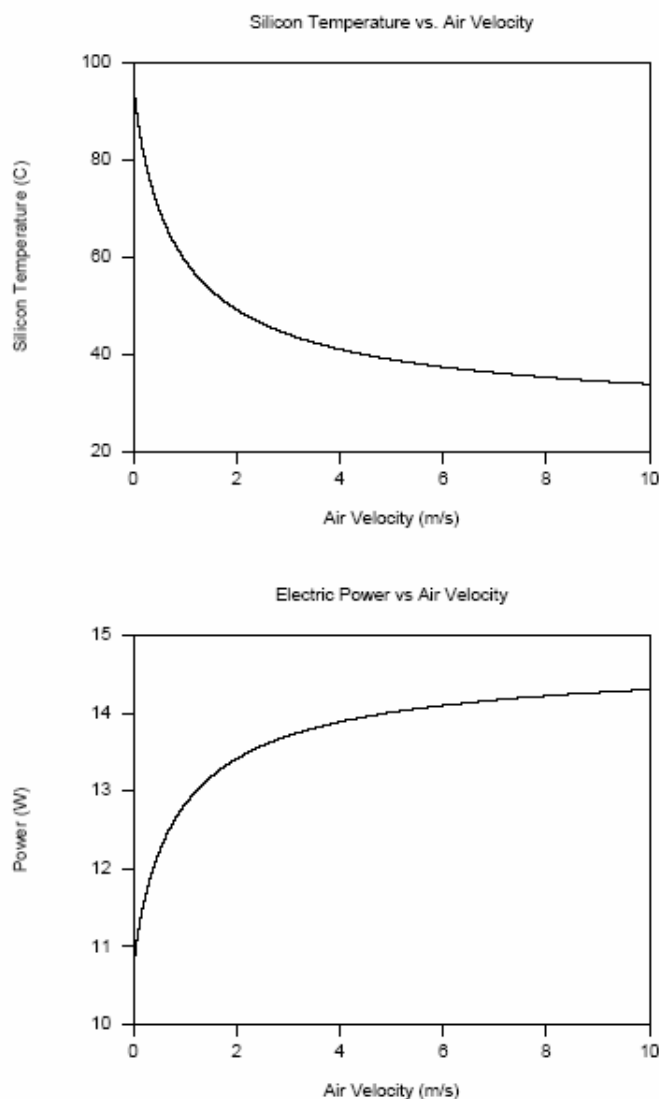

Proceeding as in Part (a) we find

$$\eta = 0.239, T_3 = T_{\text{si}} = 40.98^\circ\text{C}, T_1 = 40^\circ\text{C}, R_{t,\text{rad}} = 1.717 \text{ K/W}, P = 13.89 \text{ W} \quad <$$

(c) Solving Equations 1 through 4 over the velocity range $0 \leq u_m \leq 10 \text{ m/s}$ yields the following behavior

Continued...

PROBLEM 7.18 (Cont.)

COMMENTS: (1) Changing the orientation of the solar panel to the $L = 0.1$ m configuration reduces the temperature of the silicon semiconductor significantly. The influence of the orientation on the electric power would be more pronounced for warmer air temperatures. (2) Decreasing the air velocity results in significantly diminished power output. At very low cross flow velocities, natural convection would become significant and would lead to slightly improved power output relative to that predicted here. (3) Film temperatures for Parts (a) and (b) are 35.8°C and 32.5°C , respectively. The assumed value of the film temperature is good.

PROBLEM 7.19

KNOWN: Dimensions of a photovoltaic cell, cooling air velocity and temperature, size of concentrating lens, photovoltaic construction and properties.

FIND: (a) The electric power output and silicon temperature of a system consisting of a 400 mm \times 400 mm concentrating lens and a 100 mm \times 100 mm photovoltaic cell, (b) Variation of the electric power output and silicon temperature for 100 mm $\leq L_{\text{lens}} \leq$ 600 mm.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Tripped and turbulent boundary layer, (5) Large surroundings, (6) Negligible contact resistances.

PROPERTIES: Given, Glass: $k_g = 1.4$ W/m·K, $\varepsilon_g = 0.90$, Adhesive: $k_a = 145$ W/m·K, Solder, $k_s = 50$ W/m·K, Aluminum nitride: $k_{\text{an}} = 120$ W/m·K, Table A.4, air (assume $T_f = 70^\circ\text{C}$): $k = 0.02948$ W/m·K, $\nu = 2.022 \times 10^{-5}$ m²/s, $\text{Pr} = 0.701$.

ANALYSIS:

(a) We begin by drawing the thermal circuit,

Continued...

PROBLEM 7.19 (Cont.)

The thermal resistances are

$$R_{t,g} = L_g / (k_g A) = 3 \times 10^{-3} \text{ m} / (1.4 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 0.2143 \text{ K/W}$$

$$R_{t,a} = L_a / (k_a A) = 0.1 \times 10^{-3} \text{ m} / (145 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 6.897 \times 10^{-5} \text{ K/W}$$

$$R_{t,s} = L_s / (k_s A) = 0.1 \times 10^{-3} \text{ m} / (50 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 200 \times 10^{-6} \text{ K/W}$$

$$R_{t,an} = L_{an} / (k_{an} A) = 2 \times 10^{-3} \text{ m} / (120 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 1.67 \times 10^{-3} \text{ K/W}$$

$$h_{\text{rad,tp}} = \varepsilon_g \sigma (T_1 + T_{\text{sur}})(T_1^2 + T_{\text{sur}}^2)$$

$$R_{t,\text{rad,tp}} = \frac{1}{0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T_1 + 298 \text{ K}) \times (T_1^2 + (298 \text{ K})^2)} \quad (1)$$

$$h_{\text{rad,b}} = \varepsilon_b \sigma (T_5 + T_{\text{sur}})(T_5^2 + T_{\text{sur}}^2)$$

$$R_{t,\text{rad,b}} = \frac{1}{0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T_5 + 298 \text{ K}) \times (T_5^2 + (298 \text{ K})^2)} \quad (2)$$

For the top and bottom tripped boundary layers,

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{5 \text{ m/s} \times 0.1 \text{ m}}{2.022 \times 10^{-5} \text{ m}^2/\text{s}} = 24.73 \times 10^3$$

From Equation 7.38

Continued...

PROBLEM 7.19 (Cont.)

$$\overline{\text{Nu}}_L = 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} = 0.037 \times [24.73 \times 10^3]^{0.8} \times 0.701^{1/3} = 107.5$$

$$\bar{h} = \overline{\text{Nu}}_L k / L = \frac{107.5 \times 0.02948 \text{ W/m} \cdot \text{K}}{0.1 \text{ m}} = 31.69 \text{ W/m}^2 \cdot \text{K}$$

$$R_{t,\text{conv}} = 1/\bar{h}A = \frac{1}{(31.69 \text{ W/m}^2 \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m})} = 3.155 \text{ K/W}$$

From the thermal circuit,

$$0.83 G_c A (1 - \eta) = 0.83 G (L_{\text{lens}}/L)^2 A (1 - \eta) = q_t + q_b$$

$$0.83 \times 700 \text{ W/m}^2 \times 4^2 \times 0.1 \text{ m} \times 0.1 \text{ m} \times (1 - \eta) = q_t + q_b$$

$$9296 \text{ W} = (q_t + q_b)/(1 - \eta) \quad (3)$$

where

$$q_t = (T_3 - T_1)/(R_{t,a} + R_{t,g}) = (T_3 - T_1)/0.2144 \text{ K/W} \quad (4)$$

and

$$\begin{aligned} q_b &= (T_1 - T_{\text{sur}})/R_{t,\text{rad,tp}} + (T_1 - T_{\infty})/R_{t,\text{conv}} \\ &= (T_1 - 298 \text{ K})/R_{t,\text{rad,tp}} + (T_1 - 298 \text{ K})/3.155 \text{ K/W} \end{aligned} \quad (5)$$

Likewise

$$q_b = (T_3 - T_5)/(R_{t,s} + R_{t,ab}) = (T_3 - T_5)/1.87 \times 10^{-3} \text{ K/W} \quad (6)$$

and

$$\begin{aligned} q_b &= (T_5 - T_{\text{sur}})/R_{t,\text{rad,b}} + (T_5 - T_{\infty})/R_{t,\text{conv}} \\ &= (T_5 - 298 \text{ K})/R_{t,\text{rad,b}} + (T_5 - 298 \text{ K})/3.155 \text{ K/W} \end{aligned} \quad (7)$$

The solar-to-electrical conversion efficiency is

$$\eta = 0.28 - 0.001^\circ\text{C}^{-1} \times (T_3 - 273)^\circ\text{C} \quad (8)$$

Equations (1) through (8) may be solved simultaneously to yield

$$T_{\text{si}} = T_3 - 273 = 125.9^\circ\text{C}, \eta = 0.1541, T_1 = 390.9 \text{ K}, T_5 = 398.8 \text{ K},$$

$$R_{t,\text{rad,tp}} = 11.78 \text{ K/W}, R_{t,\text{rad,b}} = 10.75 \text{ K/W}, q_t = 37.32 \text{ W}, q_b = 41.32 \text{ W}.$$

The electric power produced is

$$\begin{aligned} P &= 0.83 G (L_{\text{lens}}/L)^2 A \eta \\ &= 0.83 \times 700 \text{ W/m}^2 \times 4^2 \times 0.1 \text{ m} \times 0.1 \text{ m} \times 0.1541 = 14.33 \text{ W} \end{aligned}$$

<
Continued...

PROBLEM 7.19 (Cont.)

(b) The *IHT* Software may be used to investigate the sensitivity of the silicon temperature and the electric power produced in response to the concentrating lense size. Results are shown below. <

COMMENTS: (1) The electric power output is highly sensitive to the size of the concentrating lens. The concentrated irradiation continually increases as the concentrator is made larger until, eventually, the silicon temperature becomes very high and the solar-to-electrical conversion efficiency becomes small. (2) The electric power could be increased if heat sinks and/or liquid cooling could be applied to the solar cell, keeping the silicon temperature low and the conversion efficiency relatively high. (3) The assumed film temperature is a good estimate since $T_{f,tp} = 71.4^\circ\text{C}$ and $T_{f,bot} = 75.4^\circ\text{C}$.

PROBLEM 7.20

KNOWN: Material properties, inner surface temperature and dimensions of roof of refrigerated truck compartment. Truck speed and ambient temperature. Solar irradiation.

FIND: (a) Outer surface temperature of roof and rate of heat transfer to compartment, (b) Effect of changing radiative properties of outer surface, (c) Effect of eliminating insulation.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible irradiation from the sky, (2) Turbulent flow over entire outer surface, (3) Average convection coefficient may be used to estimate average surface temperature, (4) Constant properties.

PROPERTIES: Table A-4, air ($p = 1 \text{ atm}$, $T_f \approx 300\text{K}$): $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0263 \text{ W/m-K}$, $\text{Pr} = 0.707$.

ANALYSIS: (a) From an energy balance for the outer surface,

$$\alpha_S G_S + q''_{\text{conv}} - E = q''_{\text{cond}} = \frac{T_{s,o} - T_{s,i}}{R''_{\text{tot}}}$$

$$\alpha_S G_S + \bar{h}(T_{\infty} - T_{s,o}) - \varepsilon \sigma T_{s,o}^4 = \frac{T_{s,o} - T_{s,i}}{2R''_p + R''_i}$$

where $R''_p = (t_1/k_p) = 2.78 \times 10^{-5} \text{ m}^2 \cdot \text{K/W}$, $R''_i = (t_2/k_i) = 1.923 \text{ m}^2 \cdot \text{K/W}$, and with $\text{Re}_L = u_{\infty} L / \nu = 29.2 \text{ m/s} \times 10 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 1.84 \times 10^7$,

$$\bar{h} = \frac{k}{L} 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} = \frac{0.0263 \text{ W/m-K}}{10 \text{ m}} 0.037 (1.84 \times 10^7)^{4/5} (0.707)^{1/3} = 56.2 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$0.5 \left(750 \text{ W/m}^2 \cdot \text{K} \right) + 56.2 \text{ W/m}^2 \cdot \text{K} (305 - T_{s,o}) - 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 T_{s,o}^4 = \frac{T_{s,o} - 263 \text{ K}}{(5.56 \times 10^{-5} + 1.923) \text{ m}^2 \cdot \text{K/W}}$$

Solving, we obtain

$$T_{s,o} = 306.8 \text{ K} = 33.8^\circ \text{C} \quad <$$

Hence, the heat load is

$$q = (W \cdot L) q''_{\text{cond}} = (3.5 \text{ m} \times 10 \text{ m}) \frac{(33.8 + 10)^\circ \text{C}}{1.923 \text{ m}^2 \cdot \text{K/W}} = 797 \text{ W} \quad <$$

(b) With the special surface finish ($\alpha_S = 0.15$, $\varepsilon = 0.8$),

Continued

PROBLEM 7.20 (Cont.)

$$T_{s,o} = 300.1\text{K} = 27.1^\circ\text{C} \quad <$$

$$q = 675.3\text{W} \quad <$$

(c) Without the insulation ($t_2 = 0$) and with $\alpha_S = \varepsilon = 0.5$,

$$T_{s,o} = 263.1\text{K} = -9.9^\circ\text{C} \quad <$$

$$q = 90,630\text{W} \quad <$$

COMMENTS: (1) Use of the special surface finish reduces the solar input, while increasing radiation emission from the surface. The cumulative effect is to reduce the heat load by 15%. (2) The thermal resistance of the aluminum panels is negligible, and without the insulation, the heat load is *enormous*.

PROBLEM 7.21

KNOWN: Surface characteristics of a flat plate in an air stream.

FIND: Orientation which minimizes convection heat transfer.

SCHEMATIC:

ASSUMPTIONS: (1) Surface B is sufficiently rough to trip the boundary layer when in the upstream position (Configuration 2).

PROPERTIES: Table A-4, Air ($T_f = 333\text{K}$, 1 atm): $\nu = 19.2 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 28.7 \times 10^{-3} \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.7$.

ANALYSIS: Since Configuration (2) results in a turbulent boundary layer over the entire surface, the lowest heat transfer is associated with Configuration (1). Find

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{20 \text{ m/s} \times 1 \text{ m}}{19.2 \times 10^{-6} \text{ m}^2/\text{s}} = 1.04 \times 10^6.$$

Hence in Configuration (1), transition will occur just before the rough surface ($x_c = 0.48\text{m}$). Note that

$$\begin{aligned} \overline{\text{Nu}}_{L,1} &= \left[0.037 \left(1.04 \times 10^6 \right)^{4/5} - 871 \right] 0.7^{1/3} = 1366 \\ \overline{\text{Nu}}_{L,2} &= 0.037 \left(1.04 \times 10^6 \right)^{4/5} (0.7)^{1/3} = 2139 > \overline{\text{Nu}}_{L,1}. \end{aligned}$$

For Configuration (1):
$$\frac{\bar{h}_{L,1} L}{k} = \overline{\text{Nu}}_{L,1} = 1366.$$

Hence

$$\bar{h}_{L,1} = 1366 \left(28.7 \times 10^{-3} \text{ W/m}\cdot\text{K} \right) / 1 \text{ m} = 39.2 \text{ W/m}^2 \cdot \text{K}$$

and

$$\begin{aligned} q_1 &= \bar{h}_{L,1} A (T_s - T_\infty) = 39.2 \text{ W/m}^2 \cdot \text{K} (0.5 \text{ m} \times 1 \text{ m}) (100 - 20) \text{ K} \\ q_1 &= 1568 \text{ W}. \end{aligned}$$

<

PROBLEM 7.22

KNOWN: Prevailing wind with prescribed speed blows past ten window panels, each of 1-m length, on a penthouse tower.

FIND: (a) Average convection coefficient for the first, third and tenth window panels when the wind speed is 5 m/s; evaluate thermophysical properties at 300 K, but determine suitability when ambient air temperature is in the range $-15 \leq T_\infty \leq 38^\circ\text{C}$; (b) Compute and plot the average coefficients for the same panels with wind speeds for the range $5 \leq u_\infty \leq 100$ km/h; explain features and relative magnitudes.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Wind over panels approximates parallel flow over a smooth flat plate, and (4) Transition Reynolds number is $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: Table A.4, Air ($T_f = 300$ K, 1 atm): $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 26.3 \times 10^{-3} \text{ W/m}\cdot\text{K}$, $Pr = 0.707$.

ANALYSIS: (a) The average convection coefficients for the first, third and tenth panels are

$$\bar{h}_1 \quad \bar{h}_{2-3} = \frac{\bar{h}_3 x_3 - \bar{h}_2 x_2}{x_3 - x_2} \quad \bar{h}_{9-10} = \frac{\bar{h}_{10} x_{10} - \bar{h}_9 x_9}{x_{10} - x_9} \quad (1,2,3)$$

where $\bar{h}_2 = \bar{h}_2(x_2)$, etc. If $Re_{x,c} = 5 \times 10^5$, with properties evaluated at $T_f = 300$ K, transition occurs at

$$x_c = \frac{\nu}{u_\infty} Re_{x,c} = \frac{15.89 \times 10^{-6} \text{ m}^2/\text{s}}{5 \text{ m/s}} \times 5 \times 10^5 = 1.59 \text{ m}$$

The flow over the first panel is laminar, and \bar{h}_1 can be estimated using Eq. (7.30).

$$\overline{Nu}_{x1} = \frac{\bar{h}_1 x_1}{k} = 0.664 Re_x^{1/2} Pr^{1/3}$$

$$\bar{h}_1 = (0.0263 \text{ W/m}\cdot\text{K} \times 0.664/\text{lm}) \left(5 \text{ m/s} \times 1 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} \right)^{1/2} (0.707)^{1/3} = 8.73 \text{ W/m}^2 \cdot \text{K} <$$

The flow over the third and tenth panels is mixed, and \bar{h}_2 , \bar{h}_3 , \bar{h}_9 and \bar{h}_{10} can be estimated using Eq. (7.41). For the third panel with $x_3 = 3$ m and $x_2 = 2$ m,

$$\overline{Nu}_{x3} = \frac{\bar{h}_3 x_3}{k} = \left(0.037 Re_x^{4/5} - 871 \right) Pr^{1/3}$$

$$\bar{h}_3 = (0.0263 \text{ W/m}\cdot\text{K}/3 \text{ m}) \times \left[0.037 \left(5 \text{ m/s} \times 3 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} \right)^{4/5} - 871 \right] (0.707)^{1/3} = 10.6 \text{ W/m}^2 \cdot \text{K}$$

Continued...

PROBLEM 7.22 (Cont.)

$$\bar{h}_2 = (0.0263 \text{ W/m} \cdot \text{K} / 2\text{m}) \times \left[0.037 \left(5 \text{ m/s} \times 2\text{m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} \right)^{4/5} - 871 \right] (0.707)^{1/3} = 8.68 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (2),

$$\bar{h}_{2-3} = \frac{10.61 \text{ W/m}^2 \cdot \text{K} \times 3\text{m} - 8.68 \text{ W/m}^2 \cdot \text{K} \times 2\text{m}}{(3-2)\text{m}} = 14.5 \text{ W/m}^2 \cdot \text{K} \quad <$$

Following the same procedure for the tenth panel, find $\bar{h}_{10} = 11.64 \text{ W/m}^2 \cdot \text{K}$ and $\bar{h}_9 = 11.71 \text{ W/m}^2 \cdot \text{K}$, and

$$\bar{h}_{9-10} = 11.1 \text{ W/m}^2 \cdot \text{K} \quad <$$

Assuming that the window panel temperature will always be close to room temperature, $T_s = 23^\circ\text{C} = 296 \text{ K}$. If T_∞ ranges from -15 to 38°C , the film temperature, $T_f = (T_s + T_\infty)/2$, will vary from 275 to 310 K . We'll explore the effect of T_f subsequently.

(b) Using the *IHT Tool, Correlations, External Flow, Flat Plate*, results were obtained for the average coefficients \bar{h} . Using Eqs. (2) and (3), average coefficients for the panels as a function of wind speed were computed and plotted.

COMMENTS: (1) The behavior of the panel average coefficients as a function of wind speed can be explained from the behavior of the local coefficient as a function of distance for difference velocities as plotted below.

Continued...

PROBLEM 7.22 (Cont.)

For low wind speeds, transition occurs near the mid-panel, making \bar{h}_1 and \bar{h}_{9-10} nearly equal and very high because of leading-edge and turbulence effects, respectively. As the wind speed increases, transition occurs closer to the leading edge. Notice how \bar{h}_{2-3} increases rather abruptly, subsequently becoming greater than \bar{h}_{9-10} . The abrupt increase in \bar{h}_1 around 30 km/h is a consequence of transition occurring with $x < 1$ m.

(2) Using the IHT code developed for the foregoing analysis with $u_\infty = 5$ m/s, the effect of T_f is tabulated below

T_f (K)	275	300	310
\bar{h}_1 (W/m ² ·K)	8.72	8.73	8.70
\bar{h}_{2-3} (W/m ² ·K)	15.1	14.5	14.2
\bar{h}_{9-10} (W/m ² ·K)	11.6	11.1	10.8

The overall effect of T_f on estimates for the average panel coefficient is slight, less than 5%.

PROBLEM 7.23

KNOWN: Design of an anemometer comprised of a thin metallic strip supported by stiff rods serving as electrodes for passage of heating current. Fine-wire thermocouple on trailing edge of strip.

FIND: (a) Relationship between electrical power dissipation per unit width of the strip in the transverse direction, P' (mW/mm), and airstream velocity u_∞ when maintained at constant strip temperature, T_s ; show the relationship graphically; (b) The uncertainty in the airstream velocity if the accuracy with which the strip temperature can be measured and maintained constant is $\pm 0.2^\circ\text{C}$; (c) Relationship between strip temperature and airstream velocity u_∞ when the strip is provided with a constant power, $P' = 30$ mW/mm; show the relationship graphically. Also, find the uncertainty in the airstream velocity if the accuracy with which the strip temperature can be measured is $\pm 0.2^\circ\text{C}$; (d) Compare features associated with each of the operating modes.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Strip has uniform temperature in the midspan region of the strip, (4) Negligible conduction in the transverse direction in the midspan region, and (5) Airstream over strip approximates parallel flow over two sides of a smooth flat plate.

ANALYSIS: (a) In the midspan region of uniform temperature T_s with no conduction in the transverse direction, all the dissipated electrical power is transferred by convection to the airstream,

$$P' = 2\bar{h}_L L (T_s - T_\infty) \quad (1)$$

where P' is the power per unit width (transverse direction). Using the *IHT Correlation Tool* for *External Flow-Flat Plate* the power as a function of airstream velocity was determined and is plotted below. The IHT tool uses the flat plate correlation, Eq. 7.30 since the flow is laminar over this velocity range.

Continued...

PROBLEM 7.23 (Cont.)

(b) By differentiation of Eq. (1), the relative uncertainties of the convection coefficient and strip temperature are, assuming the power remains constant,

$$\frac{\Delta \bar{h}_L}{\bar{h}} = - \frac{\Delta T_s}{T_s - T_\infty} \quad (2)$$

Since the flow was laminar for the range of airstream velocities, Eq. 7.30,

$$\bar{h}_L \sim u_\infty^{1/2} \quad \text{or} \quad \frac{\Delta \bar{h}_L}{\bar{h}_L} = 0.5 \frac{\Delta u_\infty}{u_\infty} \quad (3)$$

Hence, the relative uncertainty in the air velocity due to uncertainty in T_s , $\Delta T_s = \pm 0.2^\circ \text{C}$

$$\frac{\Delta u_\infty}{u_\infty} = 2 \frac{\Delta T_s}{T_s - T_\infty} = 2 \frac{\pm 0.2^\circ \text{C}}{(35 - 25)^\circ \text{C}} = \pm 4\% \quad (4) <$$

(c) Using the IHT workspace setting $P' = 30 \text{ mW/mm}$, the strip temperature T_s as a function of the airstream velocity was determined and plotted. Note that the slope of the T_s vs. u_∞ curve is steep for low velocities and relatively flat for high velocities. That is, the technique is more sensitive at lower velocities. Using Eq. (4), but with T_s dependent upon u_∞ , the relative uncertainty in u_∞ can be determined.

(d) For the constant power mode of operation, part (a), the uncertainty in u_∞ due to uncertainty in temperature measurement was found as 4%, independent of the magnitude u_∞ . For the constant-temperature mode of operation, the uncertainty in u_∞ is less than 4% for velocities less than 30 m/s, with a value of 1% around 2 m/s. However, in the upper velocity range, the error increases to 5%.

PROBLEM 7.24

KNOWN: Plate dimensions and initial temperature. Velocity and temperature of air in parallel flow over plates.

FIND: Initial rate of heat transfer from plate. Rate of change of plate temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible radiation, (2) Negligible effect of conveyor velocity on boundary layer development, (3) Plates are isothermal, (4) Negligible heat transfer from sides of plate, (5)

$Re_{x,c} = 5 \times 10^5$, (6) Constant properties.

PROPERTIES: Table A-1, AISI 1010 steel (573K): $k_p = 49.2 \text{ W/m}\cdot\text{K}$, $c = 549 \text{ J/kg}\cdot\text{K}$, $\rho = 7832 \text{ kg/m}^3$. Table A-4, Air ($p = 1 \text{ atm}$, $T_f = 433\text{K}$): $\nu = 30.4 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0361 \text{ W/m}\cdot\text{K}$, $Pr = 0.688$.

ANALYSIS: The initial rate of heat transfer from a plate is

$$q = 2\bar{h}A_s(T_i - T_\infty) = 2\bar{h}L^2(T_i - T_\infty)$$

With $Re_L = u_\infty L / \nu = 10 \text{ m/s} \times 1\text{m} / 30.4 \times 10^{-6} \text{ m}^2/\text{s} = 3.29 \times 10^5$, flow is laminar over the entire surface and

$$\overline{Nu}_L = 0.664 Re_L^{1/2} Pr^{1/3} = 0.664 (3.29 \times 10^5)^{1/2} (0.688)^{1/3} = 336$$

$$\bar{h} = (k/L) \overline{Nu}_L = (0.0361 \text{ W/m}\cdot\text{K} / 1\text{m}) 336 = 12.1 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$q = 2 \times 12.1 \text{ W/m}^2 \cdot \text{K} (1\text{m})^2 (300 - 20)^\circ\text{C} = 6780 \text{ W} \quad <$$

Performing an energy balance at an instant of time for a control surface about the plate, $-\dot{E}_{\text{out}} = \dot{E}_{\text{st}}$, we obtain (Eq. 5.2),

$$\rho \delta L^2 c \left. \frac{dT}{dt} \right|_i = -\bar{h} 2L^2 (T_i - T_\infty)$$

$$\left. \frac{dT}{dt} \right|_i = - \frac{2(12.1 \text{ W/m}^2 \cdot \text{K})(300 - 20)^\circ\text{C}}{7832 \text{ kg/m}^3 \times 0.006\text{m} \times 549 \text{ J/kg}\cdot\text{K}} = -0.26^\circ\text{C/s} \quad <$$

COMMENTS: (1) With $Bi = \bar{h}(\delta/2)/k_p = 7.4 \times 10^{-4}$, use of the lumped capacitance method is appropriate. (2) Despite the large plate temperature and the small convection coefficient, if adjoining plates are in close proximity, radiation exchange with the surroundings will be small and the assumption of negligible radiation is justifiable.

PROBLEM 7.25

KNOWN: Velocity, initial temperature, and dimensions of aluminum strip on a production line. Velocity and temperature of air in counter flow over top surface of strip.

FIND: (a) Differential equation governing temperature distribution along the strip and expression for outlet temperature, (b) Value of outlet temperature for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible variation of sheet temperature across its thickness, (2) Negligible effect of conduction along length (x) of sheet, (3) Negligible radiation, (4) Turbulent flow over entire top surface, (5) Negligible effect of sheet velocity on boundary layer development, (6) Negligible heat transfer from bottom surface and sides, (7) Constant properties.

PROPERTIES: *Table A-1*, Aluminum, 2024-T6 ($\bar{T}_{AL} \approx 500\text{K}$): $\rho = 2770\text{ kg/m}^3$, $c_p = 983\text{ J/kg}\cdot\text{K}$, $k = 186\text{ W/m}\cdot\text{K}$. *Table A-4*, Air ($p = 1\text{ atm}$, $T_f \approx 400\text{K}$): $\nu = 26.4 \times 10^{-6}\text{ m}^2/\text{s}$, $k = 0.0338\text{ W/m}\cdot\text{K}$, $Pr = 0.69$

ANALYSIS: (a) Applying conservation of energy to a stationary control surface, through which the sheet moves, steady-state conditions exist and $\dot{E}_{in} - \dot{E}_{out} = 0$. Hence, with *inflow* due to *advection* and *outflow* due to *advection* and *convection*,

$$\begin{aligned} \rho V A_c c_p (T + dT) - \rho V A_c c_p T - dq &= 0 \\ + \rho V \delta W c_p dT - h_x (dx \cdot W) (T - T_\infty) &= 0 \\ \frac{dT}{dx} &= + \frac{h_x}{\rho V \delta c_p} (T - T_\infty) \end{aligned} \quad (1) <$$

Alternatively, if the control surface is fixed to the sheet, conditions are transient and the energy balance is of the form, $-\dot{E}_{out} = \dot{E}_{st}$, or

$$\begin{aligned} -h_x (dx \cdot W) (T - T_\infty) &= \rho (dx \cdot W \cdot \delta) c_p \frac{dT}{dt} \\ \frac{dT}{dt} &= - \frac{h_x}{\rho \delta c_p} (T - T_\infty) \end{aligned}$$

Dividing the left- and right-hand sides of the equation by dx/dt and $dx/dt = -V$, respectively, equation (1) is obtained. The equation may be integrated from $x = 0$ to $x = L$ to obtain

$$\int_{T_0}^{T_1} \frac{dT}{T - T_\infty} = \frac{L}{\rho V \delta c_p} \left[\frac{1}{L} \int_0^L h_x dx \right]$$

Continued

PROBLEM 7.25 (Cont.)

where $h_x = (k/x) 0.0296 \text{Re}_x^{4/5} \text{Pr}^{1/3}$ and the bracketed term on the right-hand side of the equation reduces to $\bar{h}_L = (k/L) 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3}$.

Hence,

$$\ln\left(\frac{T_1 - T_\infty}{T_0 - T_\infty}\right) = \frac{L \bar{h}_L}{\rho V \delta c_p}$$

$$\frac{T_0 - T_\infty}{T_1 - T_\infty} = \exp\left(-\frac{L \bar{h}_L}{\rho V \delta c_p}\right) \quad <$$

(b) For the prescribed conditions, $\text{Re}_L \approx u_\infty L / \nu = 20 \text{ m/s} \times 5 \text{ m} / 26.4 \times 10^{-6} \text{ m}^2/\text{s} = 3.79 \times 10^6$ and

$$\bar{h}_L = \left(\frac{0.0338 \text{ W/m} \cdot \text{K}}{5 \text{ m}}\right) 0.037 \left(3.79 \times 10^6\right)^{4/5} (0.69)^{1/3} = 40.5 \text{ W/m}^2 \cdot \text{K}$$

$$T_0 = 20^\circ\text{C} + (280^\circ\text{C}) \exp\left(-\frac{5 \text{ m} \times 40.5 \text{ W/m}^2 \cdot \text{K}}{2770 \text{ kg/m}^3 \times 0.1 \text{ m/s} \times 0.002 \text{ m} \times 983 \text{ J/kg} \cdot \text{K}}\right) = 213^\circ\text{C} \quad <$$

COMMENTS: (1) With $T_0 = 213^\circ\text{C}$, $\bar{T}_{\text{Al}} = 530\text{K}$ and $T_f = 411\text{K}$ are close to values used to determine the material properties, and iteration is not needed. (2) For a representative emissivity of $\varepsilon = 0.2$ and $T_{\text{sur}} = T_\infty$, the maximum value of the radiation coefficient is

$h_r = \varepsilon \sigma (T_1 + T_{\text{sur}})(T_1^2 + T_{\text{sur}}^2) = 4.1 \text{ W/m}^2 \cdot \text{K} \ll \bar{h}_L$. Hence, the assumption of negligible radiation is appropriate.

PROBLEM 7.26

KNOWN: Velocity, initial temperature, properties and dimensions of steel strip on a production line. Velocity and temperature of air in cross flow over top and bottom surfaces of strip. Temperature of surroundings.

FIND: (a) Differential equation governing temperature distribution along the strip, (b) Exact solution for negligible radiation and corresponding value of outlet temperature for prescribed conditions, (c) Effect of radiation on outlet temperature, and parametric effect of sheet velocity on temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible variation of sheet temperature across its width and thickness, (2) Negligible effect of conduction along length (x) of sheet, (3) Constant properties, (4) Radiation exchange between small surface (both sides of sheet) and large surroundings, (5) Turbulent flow over top and bottom surfaces of sheet, (6) Motion of sheet has a negligible effect on the convection coefficient, ($V \ll u_\infty$), (7) Negligible heat transfer from sides of sheet.

PROPERTIES: Prescribed. Steel: $\rho = 7850 \text{ kg/m}^3$, $c_p = 620 \text{ J/kg} \cdot \text{K}$, $\varepsilon = 0.70$. Air: $k = 0.044$

$\text{W/m} \cdot \text{K}$, $\nu = 4.5 \times 10^{-5} \text{ m}^2/\text{s}$, $\text{Pr} = 0.68$.

ANALYSIS: (a) Applying conservation of energy to a stationary differential control surface, through which the sheet passes, conditions are steady and $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$. Hence, with *inflow* due to *advection* and *outflow* due to *advection*, *convection* and *radiation*

$$\begin{aligned} \rho V A_c c_p T - \rho V A_c c_p (T + dT) - 2 dq &= 0 \\ -\rho V \delta W c_p dT - 2(W dx) \left[\bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] &= 0 \\ \frac{dT}{dx} &= -\frac{2}{\rho V \delta c_p} \left[\bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] \quad (1) < \end{aligned}$$

Alternatively, if the control surface is fixed to the sheet, conditions are transient and the energy balance is of the form, $-\dot{E}_{\text{out}} = \dot{E}_{\text{st}}$, or

$$\begin{aligned} -2(W dx) \left[\bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] &= \rho (W \delta dx) c_p \frac{dT}{dt} \\ \frac{dT}{dt} &= -\frac{2}{\rho \delta c_p} \left[\bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] \end{aligned}$$

Dividing the left- and right-hand sides of the equation by dx/dt and $V = dx/dt$, respectively, Eq. (1) is obtained.

(b) Neglecting radiation, separating variables and integrating, Eq. (1) becomes

$$\int_{T_i}^T \frac{dT}{T - T_\infty} = -\frac{2 \bar{h}_W}{\rho V \delta c_p} \int_0^x dx$$

Continued

PROBLEM 7.26 (Cont.)

$$\ln\left(\frac{T - T_\infty}{T_1 - T_\infty}\right) = -\frac{2\bar{h}_W x}{\rho V \delta c_p}$$

$$T = T_\infty + (T_1 - T_\infty) \exp\left(-\frac{2\bar{h}_W x}{\rho V \delta c_p}\right) \quad (2) <$$

With $Re_W = u_\infty W / \nu = 20 \text{ m/s} \times 1 \text{ m} / 4 \times 10^{-5} \text{ m}^2/\text{s} = 5 \times 10^5$, the correlation for turbulent flow over a flat plate yields

$$\overline{Nu}_W = 0.037 Re_W^{4/5} Pr^{1/3} = 0.037 (5 \times 10^5)^{4/5} (0.68)^{1/3} = 1179$$

$$\bar{h}_W = \frac{k}{W} \overline{Nu}_W = \frac{0.044 \text{ W/m} \cdot \text{K}}{1 \text{ m}} 1179 = 51.9 \text{ W/m}^2 \cdot \text{K}$$

Hence, applying Eq. (2) at $x = L = 10 \text{ m}$,

$$T_o = 20^\circ\text{C} + (480^\circ\text{C}) \exp\left(-\frac{2 \times 51.9 \text{ W/m}^2 \cdot \text{K} \times 10 \text{ m}}{7850 \text{ kg/m}^3 \times 0.1 \text{ m/s} \times 0.003 \text{ m} \times 620 \text{ J/kg} \cdot \text{K}}\right) = 256^\circ\text{C} <$$

(c) Using the DER function of IHT, Eq. (1) may be numerically integrated from $x = 0$ to $x = L = 10 \text{ m}$ to obtain

$$T_o = 210^\circ\text{C} <$$

Contrasting this result with that of Part (b), it's clear that radiation makes a discernable contribution to cooling of the sheet. IHT was also used to determine the effect of the sheet velocity on the temperature distribution.

The sheet velocity has a significant influence on the temperature distribution. The temperature decay decreases with increasing V due to the increasing effect of advection on energy transfer in the x direction.

COMMENTS: (1) A critical parameter in the production process is the *coiling temperature*, that is, the temperature at which the wire may be safely coiled for subsequent storage or shipment. The larger the production rate (V), the longer the cooling distance needed to achieve a desired coiling temperature. (2) Cooling may be enhanced by increasing the cross stream velocity u_∞ .

PROBLEM 7.27

KNOWN: Length, thickness, speed and temperature of steel strip.

FIND: Rate of change of strip temperature 1 m from leading edge and at trailing edge. Location of minimum cooling rate.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation, (3) Negligible longitudinal conduction in strip, (4) Critical Reynolds number is 5×10^5 .

PROPERTIES: Steel (given): $\rho = 7900 \text{ kg/m}^3$, $c_p = 640 \text{ J/kg}\cdot\text{K}$. Table A-4, Air ($\bar{T} = 750 \text{ K}$, 1 atm): $\nu = 76.4 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0549 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.702$.

ANALYSIS: Performing an energy balance for a control mass of unit surface area A_s riding with the strip,

$$-\dot{E}_{\text{out}} = dE_{\text{st}}/dt$$

$$-2h_x A_s (T - T_\infty) = \rho \delta A_s c_p (dT/dt)$$

$$dT/dt = \frac{-2h_x (T - T_\infty)}{\rho \delta c_p} = -\frac{2(900 \text{ K})h_x}{7900 \text{ kg/m}^3 (0.003 \text{ m}) 640 \text{ J/kg}\cdot\text{K}} = -0.119 h_x \text{ (K/s)}.$$

$$\text{At } x = 1 \text{ m, } \text{Re}_x = \frac{Vx}{\nu} = \frac{20 \text{ m/s}(1 \text{ m})}{76.4 \times 10^{-6} \text{ m}^2/\text{s}} = 2.62 \times 10^5 < \text{Re}_{x,c}. \text{ Hence,}$$

$$h_x = (k/x) 0.332 \text{Re}_x^{1/2} \text{Pr}^{1/3} = \frac{0.0549 \text{ W/m}\cdot\text{K}}{1 \text{ m}} (0.332) (2.62 \times 10^5)^{1/2} (0.702)^{1/3} = 8.29 \text{ W/m}^2 \cdot \text{K}$$

$$\text{and at } x = 1 \text{ m, } dT/dt = -0.987 \text{ K/s.} \quad <$$

$$\text{At the trailing edge, } \text{Re}_x = 2.62 \times 10^7 > \text{Re}_{x,c}. \text{ Hence}$$

$$h_x = (k/x) 0.0296 \text{Re}_x^{4/5} \text{Pr}^{1/3} = \frac{0.0549 \text{ W/m}\cdot\text{K}}{100 \text{ m}} (0.0296) (2.62 \times 10^7)^{4/5} (0.702)^{1/3} = 12.4 \text{ W/m}^2 \cdot \text{K}$$

$$\text{and at } x = 100 \text{ m, } dT/dt = -1.47 \text{ K/s.} \quad <$$

The minimum cooling rate occurs just before transition; hence, for $\text{Re}_{x,c} = 5 \times 10^5$

$$x_c = 5 \times 10^5 (\nu/V) = \frac{5 \times 10^5 \times 76.4 \times 10^{-6} \text{ m}^2/\text{s}}{20 \text{ m/s}} = 1.91 \text{ m} \quad <$$

COMMENTS: The cooling rates are very low and would remain low even if radiation were considered. For this reason, hot strip metals are quenched by water and not by air.

PROBLEM 7.28

KNOWN: Thin metallic strip with thermocouple at trailing edge is used as an anemometer. Laminar flow.

FIND: (a) Calibration equations for constant surface temperature and constant heat flux conditions. (b) Percentage error in using the wrong calibration. (c) Location of thermocouple for which calibration is insensitive to thermal boundary condition.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Boundary layer assumptions hold, (3) Laminar flow, (4) Constant properties.

ANALYSIS:

(a) For constant surface temperature

$$\overline{Nu}_L = 0.664 Re_L^{1/2} Pr^{1/3}$$

Therefore

$$\bar{h}_L = 0.664 Re_L^{1/2} Pr^{1/3} k/L$$

$$\text{and } P' = 2\bar{h}_L L (T_s - T_\infty) = 2 (0.664) \left(\frac{u_\infty L}{\nu} \right)^{1/2} Pr^{1/3} (T_s - T_\infty)$$

Solving for u_∞ , the calibration for constant T_s is:

$$u_\infty = \left\{ P' / \left[2 (0.664) Pr^{1/3} k (T_s - T_\infty) \right] \right\}^2 \left(\frac{\nu}{L} \right) \quad (1)$$

For constant heat flux, we consider the local heat transfer coefficient at the end of the strip.

$$\overline{Nu}_L = 0.453 Re_L^{1/2} Pr^{1/3}$$

$$\bar{h}_L = 0.453 Re_L^{1/2} Pr^{1/3} k/L$$

Accounting for heat loss from both surfaces,

$$P' = 2q_s'' L$$

The uniform heat flux can be related to the conditions at $x = L$:

$$q_s'' = h_L (T_{s,L} - T_\infty)$$

Thus

$$P' = 2h_L L (T_{s,L} - T_\infty) = 2 (0.453) \left(\frac{u_\infty L}{\nu} \right)^{1/2} Pr^{1/3} k (T_{s,L} - T_\infty)$$

Continued...

PROBLEM 7.28 (Cont.)

Solving for u_∞ , the calibration for constant q_s'' is:

$$u_\infty = \left\{ P' / \left[2 (0.453) \text{Pr}^{1/3} k (T_{s,L} - T_\infty) \right] \right\}^2 \left(\frac{\nu}{L} \right) \quad (2) <$$

(b) Since the true situation is uniform heat flux, the true velocity is found from Equation (2). However the predicted velocity is incorrectly calculated from Equation (1). Thus

$$\frac{u_{\infty, \text{pred.}}}{u_{\infty, \text{true}}} = \left(\frac{0.453}{0.664} \right)^2 = 0.47 <$$

The velocity is underpredicted by more than half, or 53%.

(c) For constant surface heat flux, the local surface temperature is given by

$$T_{s,q}(x) - T_\infty = q_s'' / h_x = \frac{P'/2L}{0.453 \text{Re}_x^{1/2} \text{Pr}^{1/3} k/x}$$

where the q subscript on T_s indicates that it is for the constant heat flux case. This should be equal to the surface temperature for the constant T_s case, namely

$$T_{s,T} - T_\infty = P'/2L \bar{h}_L = \frac{P'/2L}{0.664 \text{Re}_L^{1/2} \text{Pr}^{1/3} k/L}$$

Equating $T_{s,q}$ and $T_{s,T}$ and solving for x yields

$$\begin{aligned} 0.453x^{-1/2} &= 0.664L^{-1/2} \\ (x/L) &= \left(\frac{0.453}{0.664} \right)^2 = 0.47 < \end{aligned}$$

Thus, if the thermocouple is placed approximately at the midpoint of the strip it will be insensitive to the type of thermal boundary condition experienced by the strip.

PROBLEM 7.29

KNOWN: Dimensions of aluminum heat sink. Temperature and velocity of coolant (water) flow through the heat sink. Power dissipation of electronic package attached to the heat sink.

FIND: Base temperature of heat sink.

SCHEMATIC:

ASSUMPTIONS: (1) Average convection coefficient association with flow over fin surfaces may be approximated as that for a flat plate in parallel flow, (2) All of the electric power is dissipated by the heat sink, (3) Transition Reynolds number of $Re_{x,c} = 5 \times 10^5$, (4) Constant properties.

PROPERTIES: Given. Aluminum: $k_{hs} = 180 \text{ W/m}\cdot\text{K}$. Water: $k_w = 0.62 \text{ W/m}\cdot\text{K}$, $\nu = 7.73 \times 10^{-7} \text{ m}^2/\text{s}$, $Pr = 5.2$.

ANALYSIS: From the thermal circuit,

$$q = P_{elec} = \frac{T_b - T_\infty}{R_b + R_{t,o}}$$

where $R_b = L_b / k_{hs} (w_1 \times w_2) = 0.01 \text{ m} / 180 \text{ W/m}\cdot\text{K} (0.10 \text{ m})^2 = 5.56 \times 10^{-3} \text{ K/W}$ and, from Eqs. 3.102 and 3.103,

$$R_{t,o} = \left\{ \bar{h} A_t \left[1 - \frac{NA_f}{A_t} (1 - \eta_f) \right] \right\}^{-1}$$

The fin and total surface area of the array are $A_f = 2w_2 (L_f + t/2) = 0.2 \text{ m} (0.055 \text{ m}) = 0.011 \text{ m}^2$ and $A_t = NA_f + A_b = NA_f + (N-1)(S-t)w_2 = 6(0.011 \text{ m}^2) + 5(0.008 \text{ m})0.1 \text{ m} = (0.066 + 0.004) = 0.070 \text{ m}^2$.

With $Re_{w_2} = u_\infty w_2 / \nu = 3 \text{ m/s} \times 0.10 \text{ m} / 7.73 \times 10^{-7} \text{ m}^2/\text{s} = 3.88 \times 10^5$, laminar flow may be assumed over the entire surface. Hence

$$\bar{h} = \left(\frac{k_w}{w_2} \right) 0.664 Re_{w_2}^{1/2} Pr^{1/3} = \left(\frac{0.62 \text{ W/m}\cdot\text{K}}{0.10 \text{ m}} \right) 0.664 (3.88 \times 10^5)^{1/2} (5.2)^{1/3} = 4443 \text{ W/m}^2\cdot\text{K}$$

With $m = (2\bar{h}/k_{hs}t)^{1/2} = (2 \times 4443 \text{ W/m}^2\cdot\text{K} / 180 \text{ W/m}\cdot\text{K} \times 0.01 \text{ m})^{1/2} = 70.3 \text{ m}^{-1}$, $mL_c = 70.3 \text{ m}^{-1} (0.055 \text{ m}) = 3.86$ and $\tanh mL_c = 0.9991$, Eq. 3.89 yields

$$\eta_f = \frac{\tanh mL_c}{mL_c} = \frac{0.9991}{3.86} = 0.259$$

Continued

PROBLEM 7.29 (Cont.)

Hence,

$$R_{t,o} = \left\{ 4443 \text{ W/m}^2 \cdot \text{K} \times 0.070 \text{ m}^2 \left[1 - \frac{0.066 \text{ m}^2}{0.070 \text{ m}^2} (1 - 0.259) \right] \right\}^{-1} = 0.0107 \text{ K/W} \quad <$$

and

$$T_b = T_\infty + P_{\text{elec}} (R_b + R_{t,o}) = 17^\circ\text{C} + 1800 \text{ W} (5.56 \times 10^{-3} + 0.0107) \text{ K/W} = 46.2^\circ\text{C} \quad <$$

COMMENTS: (1) The boundary layer thickness at the trailing edge of the fin is

$\delta = 5w_2 / (\text{Re}_{w_2})^{1/2} = 0.80 \text{ mm} \ll (S - t)$. Hence, the assumption of parallel flow over a flat plate is reasonable. (2) If a finned heat sink is not employed and heat transfer is simply by convection from the $w_2 \times w_2$ base surface, the corresponding convection resistance would be 0.0225 K/W , which is only twice the resistance associated with the fin array. The small enhancement by the array is attributable to the large value of \bar{h} and the correspondingly small value of η_f . Were a fluid such as air or a dielectric liquid used as the coolant, the much smaller thermal conductivity would yield a smaller \bar{h} , a larger η_f and hence a larger effectiveness for the array.

PROBLEM 7.30

KNOWN: Dimensions of aluminum heat sink. Temperature of air flow through the heat sink. Base temperature of heat sink. Power dissipation of electronic package attached to the heat sink.

FIND: Required air velocity.

SCHEMATIC:

ASSUMPTIONS: (1) Average convection coefficient association with flow over fin surfaces may be approximated as that for a flat plate in parallel flow, (2) All of the electric power is dissipated by the heat sink, (3) Transition Reynolds number of $Re_{x,c} = 5 \times 10^5$, (4) Constant properties.

PROPERTIES: Given. Aluminum: $k_{hs} = 180 \text{ W/m}\cdot\text{K}$. Air: $k_a = 0.027 \text{ W/m}\cdot\text{K}$, $\nu = 16.4 \times 10^{-6} \text{ m}^2/\text{s}$, and $Pr = 0.706$.

ANALYSIS: From the thermal circuit,

$$q = P_{elec} = \frac{T_b - T_{\infty}}{R_b + R_{t,o}}$$

where $R_b = L_b / k_{hs} (w_1 \times w_2) = 0.01 \text{ m} / 180 \text{ W/m}\cdot\text{K} (0.10 \text{ m})^2 = 5.56 \times 10^{-3} \text{ K/W}$. Thus we require

$$R_{t,o} = (T_b - T_{\infty}) / q - R_b = (70^\circ - 20^\circ\text{C}) / 70 \text{ W} - 5.56 \times 10^{-3} \text{ K/W} = 0.709 \text{ K/W}$$

From Eqs. 3.102 and 3.103,

$$R_{t,o} = \left\{ \bar{h} A_t \left[1 - \frac{NA_f}{A_t} (1 - \eta_f) \right] \right\}^{-1} = 0.709 \text{ K/W} \quad (1)$$

where the fin area is $A_f = 2w_2 (L_f + t/2) = 0.2 \text{ m} (0.055 \text{ m}) = 0.011 \text{ m}^2$, $NA_f = 0.066 \text{ m}^2$, and

$A_t = NA_f + A_b = NA_f + (N-1)(S-t)w_2 = 0.066 \text{ m}^2 + 5(0.008 \text{ m})0.1 \text{ m} = 0.070 \text{ m}^2$. The fin efficiency is given by Eq. 3.89:

$$\eta_f = \frac{\tanh mL_c}{mL_c} \quad (2)$$

where $m = (2\bar{h} / k_{hs}t)^{1/2}$ and $L_c = L_f + t/2 = 0.055 \text{ m}$. Since only \bar{h} is unknown in the expression for η_f , Eqs. (1) and (2) can be solved for the two unknowns, \bar{h} and η_f . The iterations can be initiated by assuming $\eta_f = 1$ in Eq. (1), which results in $\bar{h} = 20.2 \text{ W/m}^2\cdot\text{K}$. Then $m = 4.73$ and Eq. (2) yields $\eta_f = 0.978$. Continuing the iterations until converged, we find $\bar{h} = 20.6 \text{ W/m}^2\cdot\text{K}$.

Continued.....

PROBLEM 7.30 (Cont.)

Now we can proceed to find the velocity that would yield this heat transfer coefficient. Assuming laminar flow,

$$\text{Nu}_{w_2} = 0.664 \text{Re}_{w_2}^{1/2} \text{Pr}^{1/3}$$

$$\text{Re}_{w_2} = \left(\frac{\bar{h} w_2}{k_a} \text{Pr}^{-1/3} / 0.664 \right)^2 = \left(\frac{20.6 \text{ W/m}^2 \cdot \text{K} \times 0.1 \text{ m}}{0.027 \text{ W/m} \cdot \text{K}} 0.706^{-1/3} / 0.664 \right)^2 = 16,650$$

The assumption of laminar flow is correct. Then,

$$u_\infty = \text{Re}_{w_2} \nu / w_2 = 16,650 \times 16.4 \times 10^{-6} \text{ m}^2/\text{s} / 0.10 \text{ m} = 2.73 \text{ m/s}$$

<

COMMENTS: (1) The hydrodynamic boundary layer thickness at the trailing edge of the fin is

$\delta = 5 w_2 / (\text{Re}_{w_2})^{1/2} = 3.9 \text{ mm}$, and the thermal boundary layer thickness is $\delta(\text{Pr})^{-1/3} = 4.4 \text{ mm}$. Since this is greater than the half-spacing between fins, the assumption of boundary layer flow throughout the entire heat sink is not accurate, and the actual heat transfer would be somewhat less. (2) If a finned heat sink is not employed and heat transfer is simply by convection from the $w_2 \times w_2$ base surface, the corresponding convection resistance would be 4.85 K/W , which is almost seven times the resistance associated with the fin array. The large heat transfer enhancement of the array is attributable to the rather small value of \bar{h} and the correspondingly large value of η_f , which means that the large area of the fin array remains close to the base temperature. As a result, the heat transfer enhancement is nearly proportional to the increase in area of a factor of seven.

PROBLEM 7.31

KNOWN: Dimensions of a photovoltaic cell, material and dimensions of a finned heat sink, solar irradiation and dimensions of concentrating lens, velocity and temperature of dielectric liquid.

FIND: (a) Electric power produced and silicon temperature for a square concentrating lens with the heat sink in place, (b) Electric power and silicon temperature without the heat sink, (c) Electric power and silicon temperature for $100 \text{ mm} \leq L_{\text{lens}} \leq 3000 \text{ mm}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Average convection coefficient associated with flow over fin surfaces may be approximated as that for a flat plate in parallel flow, (5) Transition Reynolds number of $Re_{x,c} = 5 \times 10^5$, (6) Negligible convection off of the top of the solar cell, (7), No radiation to or through the dielectric liquid.

PROPERTIES: Given: Aluminum: $k_{\text{Al}} = 180 \text{ W/m}\cdot\text{K}$, Dielectric liquid: $k_d = 0.064 \text{ W/m}\cdot\text{K}$, $\nu = 10^{-6} \text{ m}^2/\text{s}$, Pr = 25, Glass: $k_g = 1.4 \text{ W/m}\cdot\text{K}$, Adhesive: , $k_a = 145 \text{ W/m}\cdot\text{K}$, Solder: $k_s = 50 \text{ W/m}\cdot\text{K}$, Aluminum Nitride: $k_{\text{AN}} = 120 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) The base resistance is

$$R_b = L_b / k_{hs} (w_1 \times w_2) = \frac{0.01\text{m}}{180 \text{ W/m} \cdot \text{K} (0.10\text{m})^2} = 5.56 \times 10^{-3} \text{ K/W}$$

and, from Equations 3.102 and 3.103

$$R_{t,o} = \left\{ \bar{h}A_t \left[1 - \frac{NA_f}{A_t} (1 - \eta_f) \right] \right\}^{-1}$$

The fin and total surface areas of the array are

$$= 6(0.0110 \text{ m}^2) + 5(0.008 \text{ m})(0.100 \text{ m}) = 0.0660 \text{ m}^2 + 0.0040 \text{ m}^2 = 0.071 \text{ m}^2$$

Continued...

PROBLEM 7.31 (Cont.)

with $Re_{w2} = u_{\infty} w_2 / \nu = 3 \text{ m/s} \times 0.10 \text{ m} / 10^{-6} \text{ m}^2/\text{s} = 3.00 \times 10^5$, laminar flow may be assumed over the entire surface. Hence

$$\begin{aligned}\bar{h} &= \left(\frac{k_w}{w_2} \right) 0.664 Re_{w2}^{1/2} Pr^{1/3} \\ &= \left(\frac{0.064 \text{ W/m} \cdot \text{K}}{0.10 \text{ m}} \right) 0.664 (3.00 \times 10^5)^{1/2} (25)^{1/3} = 681 \text{ W/m}^2 \cdot \text{K}\end{aligned}$$

$$\begin{aligned}\text{with } m &= (2\bar{h}/k_{hs}t)^{1/2} = \left[362 \text{ W/m}^2 / (180 \text{ W/m} \cdot \text{K} \times 0.01 \text{ m}) \right]^{1/2} = 27.50 \text{ m}^{-1} \\ mL_c &= 27.50 \text{ m}^{-1} (0.055 \text{ m}) = 1.51 \quad \text{and} \quad \tanh mL_c = 0.907 \quad \text{Equation 3.89 yields} \\ \eta_f &= \frac{\tanh mL_c}{mL_c} = \frac{0.907}{1.51} = 0.600\end{aligned}$$

Hence,

$$R_{t,o} = \left\{ 681 \text{ W/m}^2 \cdot \text{K} \times 0.070 \text{ m}^2 \left[1 - \frac{0.066 \text{ m}^2}{0.070 \text{ m}^2} (0.400) \right] \right\}^{-1} = 33.70 \times 10^{-3} \text{ K/W}$$

The conduction resistances are

$$R_{t,g} = \frac{L_g}{k_g A} = 3 \times 10^{-3} \text{ m} / (1.4 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 0.2143 \text{ K/W}$$

$$R_{t,a} = \frac{L_a}{k_a A} = 0.1 \times 10^{-3} \text{ m} / (145 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 6.897 \times 10^{-5} \text{ K/W}$$

$$R_{t,s} = \frac{L_s}{k_s A} = 0.1 \times 10^{-3} \text{ m} / (50 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 200 \times 10^{-6} \text{ K/W}$$

$$R_{t,an} = \frac{L_{an}}{k_{an} A} = 2 \times 10^{-3} \text{ m} / (120 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 1.67 \times 10^{-3} \text{ K/W}$$

$$R_{t,c} = \frac{R_{t,c}''}{A} = 0.5 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} / (0.1 \text{ m} \times 0.1 \text{ m}) = 5.0 \times 10^{-3} \text{ K/W}$$

$$h_{\text{rad,top}} = \varepsilon_g \sigma (T_1 + T_{\text{sur}})(T_1^2 + T_{\text{sur}}^2)$$

$$R_{t,\text{rad,top}} = 1 / 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T_1 + 298 \text{ K}) \times (T_1^2 + (298 \text{ K})^2) \quad (1)$$

The thermal circuit is

Continued...

PROBLEM 7.31 (Cont.)

where $G_c = G(L_{\text{lens}}/w_1)^2$

From the thermal circuit,

$$\begin{aligned} 0.83G(L_{\text{lens}}/w_1)^2(w_1 \times w_2)(1 - \eta) &= q_{\text{top}} + q_{\text{bot}} \\ 0.83 \times 700 \text{ W/m}^2(4)^2(0.1 \text{ m} \times 0.1 \text{ m})(1 - \eta) &= q_{\text{top}} + q_{\text{bot}} \\ 92.96 \text{ W}(1 - \eta) &= q_{\text{top}} + q_{\text{bot}} \end{aligned} \quad (2)$$

$$\begin{aligned} q_{\text{top}} &= (T_3 - T_{\text{sur}}) / (R_{t,a} + R_{t,g} + R_{t,\text{rad,top}}) \\ &= (T_{\text{si}} - 298 \text{ K}) / (6.897 \times 10^{-5} \text{ K/W} + 0.2143 \text{ K/W} + R_{t,\text{rad,top}}) \\ &= (T_{\text{si}} - 298 \text{ K}) / (0.2143 \text{ K/W} + R_{t,\text{rad,top}}) \end{aligned} \quad (3)$$

$$\begin{aligned} q_{\text{bot}} &= (T_3 - T_{\infty}) / (R_{t,o} + R_{t,c} + R_{t,an} + R_{t,s}) \\ &= (T_{\text{si}} - 298 \text{ K}) / (33.70 \times 10^{-3} \text{ K/W} + 5.0 \times 10^{-3} \text{ K/W} + 1.67 \times 10^{-3} \text{ K/W} + 0.20 \times 10^{-3} \text{ K/W}) \\ &= (T_{\text{si}} - 298 \text{ K}) / (40.57 \times 10^{-3} \text{ K/W}) \end{aligned} \quad (4)$$

From the problem statement

$$\eta = 0.28 - 0.001^\circ\text{C}^{-1}(T_{\text{si}} - 273)^\circ\text{C} \quad (5)$$

Solving Equations (1) through (5) simultaneously yields

$$T_{\text{si}} = 28.2^\circ\text{C}, \quad \eta = 0.252 \quad <$$

The electric power is

$$P = 0.83G(L_{\text{lens}}/w_1)^2(w_1 \times w_2)(\eta) \quad (6)$$

$$P = 0.83 \times 700 \text{ W/m}^2(4)^2(0.1 \text{ m} \times 0.1 \text{ m})(0.252) = 23.4 \text{ W} \quad <$$

(b) Substituting $L_{\text{lens}} = 1500 \text{ mm}$ in Equations 2 and 6 yields

$$T_{\text{si}} = 72.6^\circ\text{C}, \quad P = 271 \text{ W} \quad <$$

with the heat sink in place. For no heat sink we also substitute

$$R_{t,c} = 0 \text{ and } R_{t,o} = R_{t,\text{conv}} = 1/\bar{h}w_1^2 = 1/681 \text{ W/m}^2\cdot\text{K}(0.1\text{m})^2 = 146.8 \times 10^{-3} \text{ K/W}$$

into Equation 4 and solving Equations (1) through (5) simultaneously yields

PROBLEM 7.31 (Cont.)

$$T_{\text{si}} = 200^\circ\text{C}, P = 105 \text{ W}$$

<

(c) The variation of the silicon temperature and electric power with the heat sink in place is shown in the accompanying graphs.

Continued...

PROBLEM 7.31 (Cont.)

COMMENTS: (1) In Problem 7.19, we see that, for air cooling and $L_{\text{lens}} = 400 \text{ mm}$, $T_{\text{si}} = 126 \text{ }^{\circ}\text{C}$, $P = 14.3 \text{ W}$. Use of liquid cooling increases the electrical power output to 23.4 W, or 64 percent. In Problem 7.19 we see the maximum power output to be about 15 W. With liquid cooling and the heat sink, maximum power output increases to about 420 W, or 2800%. (2) The electric power is highly sensitive to the size of the concentrator. Initially, the power output increases as the concentrated irradiation increases, but as the silicon temperature increases the efficiency drops, driving the power output down. (3) The boundary layer thickness at the trailing edge of the fin is $\delta = 5w_2 / \text{Re}_{w_2}^{1/2} = 0.91 \text{ mm} \ll (S - t)$. Also, since $\text{Pr} > 1$, $\delta_t < \delta$. Hence, the assumption of parallel flow over a flat plate is reasonable. (4) Solar irradiation values can be nearly 1100 W/m^2 in clear environments. How do you think the maximum electric power will change when the solar irradiation is increased? You may want to re-work the solution to the problem to find the surprising result.

PROBLEM 7.32

KNOWN: Operating power of electrical components attached to one side of copper plate. Contact resistance. Velocity and temperature of water flow on opposite side.

FIND: (a) Plate temperature, (b) Component temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss from sides and bottom, (4) Turbulent flow throughout.

PROPERTIES: Water (given): $\nu = 0.96 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.620 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 5.2$.

ANALYSIS: (a) From the convection rate equation,

$$T_s = T_\infty + q/\bar{h}A$$

where $q = Nq_c = 2500 \text{ W}$ and $A = L^2 = 0.04 \text{ m}^2$. The convection coefficient is given by the turbulent flow correlation

$$\bar{h} = \overline{\text{Nu}}_L (k/L) = 0.037 \text{Re}_L^{4/5} \text{Pr}^{1/3} (k/L)$$

where

$$\text{Re}_L = (u_\infty L / \nu) = (2 \text{ m/s} \times 0.2 \text{ m}) / 0.96 \times 10^{-6} \text{ m}^2/\text{s} = 4.17 \times 10^5$$

and hence

$$\bar{h} = 0.037 \left(4.17 \times 10^5 \right)^{4/5} (5.2)^{1/3} (0.62 \text{ W/m}\cdot\text{K} / 0.2 \text{ m}) = 6228 \text{ W/m}^2 \cdot \text{K}.$$

The plate temperature is then

$$T_s = 17^\circ\text{C} + 2500 \text{ W} / \left(6228 \text{ W/m}^2 \cdot \text{K} \right) (0.20 \text{ m})^2 = 27^\circ\text{C}. \quad <$$

(b) For an individual component, a rate equation involving the component's contact resistance can be used to find its temperature,

$$q_c = (T_c - T_s) / R_{t,c} = (T_c - T_s) / (R''_{t,c} / A_c)$$

$$T_c = T_s + q_c R''_{t,c} / A_c = 27^\circ\text{C} + 25 \text{ W} \left(2 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} \right) / 10^{-4} \text{ m}^2$$

$$T_c = 77^\circ\text{C}. \quad <$$

COMMENTS: With $\text{Re}_L = 4.17 \times 10^5$, the boundary layer would be laminar over the entire plate without the boundary layer trip, causing T_s and T_c to be appreciably larger.

PROBLEM 7.33

KNOWN: Air at 27°C with velocity of 10 m/s flows turbulently over a series of electronic devices, each having dimensions of 4 mm × 4 mm and dissipating 40 mW.

FIND: (a) Surface temperature T_s of the fourth device located 15 mm from the leading edge, (b) Compute and plot the surface temperatures of the first four devices for the range $5 \leq u_\infty \leq 15$ m/s, and (c) Minimum free stream velocity u_∞ if the surface temperature of the hottest device is not to exceed 80°C.

SCHEMATIC:

ASSUMPTIONS: (1) Turbulent flow, (2) Heat from devices leaving through top surface by convection only, (3) Device surface is isothermal, and (4) The average coefficient for the devices is equal to the local value at the mid position, i.e. $\bar{h}_4 = h_x(L)$.

PROPERTIES: Table A.4, Air (assume $T_s = 330$ K, $\bar{T} = (T_s + T_\infty)/2 = 315$ K, 1 atm): $k = 0.0274$ W/m·K, $\nu = 17.40 \times 10^{-6}$ m²/s, $\alpha = 24.7 \times 10^{-6}$ m²/s, $Pr = 0.705$.

ANALYSIS: (a) From Newton's law of cooling,

$$T_s = T_\infty + q_{conv}/\bar{h}_4 A_s \quad (1)$$

where \bar{h}_4 is the average heat transfer coefficient over the 4th device. Since flow is turbulent, it is reasonable and convenient to assume that

$$\bar{h}_4 = h_x(L = 15 \text{ mm}). \quad (2)$$

To estimate h_x , use the turbulent correlation evaluating thermophysical properties at $\bar{T}_f = 315$ K (assume $T_s = 330$ K),

$$Nu_x = 0.0296 Re_x^{4/5} Pr^{1/3}$$

where

$$Re_x = \frac{u_\infty L}{\nu} = \frac{10 \text{ m/s} \times 0.015 \text{ m}}{17.4 \times 10^{-6} \text{ m}^2/\text{s}} = 8621$$

giving

$$Nu_x = \frac{h_x L}{k} = 0.0296 (8621)^{4/5} (0.705)^{1/3} = 37.1$$

$$\bar{h}_4 = h_x = \frac{Nu_x k}{L} = \frac{37.1 \times 0.0274 \text{ W/m} \cdot \text{K}}{0.015 \text{ m}} = 67.8 \text{ W/m}^2 \cdot \text{K}$$

Hence, with $A_s = 4 \text{ mm} \times 4 \text{ mm}$, the surface temperature is

$$T_s = 300 \text{ K} + \frac{40 \times 10^{-3} \text{ W}}{67.8 \text{ W/m}^2 \cdot \text{K} \times (4 \times 10^{-3} \text{ m})^2} = 337 \text{ K} = 64^\circ \text{C}.$$

<

Continued...

PROBLEM 7.33 (Cont.)

(b) The surface temperature for each of the four devices ($i = 1, 2, 3, 4$) follows from Eq. (1),

$$T_{s,i} = T_{\infty} + q_{\text{conv}} / \bar{h}_i A_s \quad (3)$$

For devices 2, 3 and 4, \bar{h}_i is evaluated as the local coefficient at the mid-positions, Eq. (2), $x_2 = 6.5$ mm, $x_3 = 10.75$ mm and $x_4 = 15$ mm. For device 1, \bar{h}_1 is the average value 0 to x_1 , where evaluated $x_1 = L_1 = 4.25$ mm. Using Eq. (3) in the *IHT Workspace* along with the *Correlations Tool, External Flow, Local Coefficient for Laminar or Turbulent Flow*, the surface temperatures $T_{s,i}$ are determined as a function of the free stream velocity.

(c) Using the *Explore* option on the *Plot Window* associated with the IHT code of part (b), the minimum free stream velocity of

$$u_{\infty} = 6.6 \text{ m/s}$$

<

will maintain device 4, the hottest of the devices, at a temperature $T_{s,4} = 80^\circ\text{C}$.

COMMENTS: (1) Note that the thermophysical properties were evaluated at a reasonable assumed film temperature in part (a).

(2) From the $T_{s,i}$ vs. u_{∞} plots, note that, as expected, the surface temperatures of the devices increase with distance from the leading edge.

PROBLEM 7.34

KNOWN: Convection correlation for irregular surface due to electronic elements mounted on a circuit board experiencing forced air cooling with prescribed temperature and velocity

FIND: Surface temperature when heat dissipation rate is 30 mW for chip of prescribed area located a specific distance from the leading edge.

SCHEMATIC:

ASSUMPTIONS: (1) Situation approximates parallel flow over a flat plate with prescribed correlation, (2) Heat rate is from top surface of chip.

PROPERTIES: Table A-4, Air (assume $T_s \approx 45^\circ\text{C}$, then $\bar{T} = (45 + 25)^\circ\text{C}/2 \approx 310\text{ K}$, 1 atm): $k = 0.027\text{ W/m}\cdot\text{K}$, $\nu = 16.90 \times 10^{-6}\text{ m}^2/\text{s}$, $\text{Pr} = 0.706$.

ANALYSIS: For the chip upper surface, the heat rate is

$$q_{\text{chip}} = \bar{h}_{\text{chip}} A_s (T_s - T_\infty) \quad \text{or} \quad T_s = T_\infty + q_{\text{chip}} / \bar{h}_{\text{chip}} A_s$$

Assuming the average convection coefficient over the chip length to be equal to the local value at the center of the chip ($x = x_o$), $\bar{h}_{\text{chip}} \approx h_x(x_o)$, where

$$\text{Nu}_x = 0.04 \text{Re}_x^{0.85} \text{Pr}^{0.33}$$

$$\text{Nu}_x = 0.04 \left(10\text{ m/s} \times 0.120\text{ m} / 16.90 \times 10^{-6}\text{ m}^2/\text{s} \right)^{0.85} (0.706)^{0.33} = 473.4$$

$$h_x = \frac{\text{Nu}_x k}{x_o} = \frac{473.4 \times 0.027\text{ W/m}\cdot\text{K}}{0.120\text{ m}} = 107\text{ W/m}^2\cdot\text{K}$$

Hence,

$$T_s = 25^\circ\text{C} + 30 \times 10^{-3}\text{ W} / 107\text{ W/m}^2\cdot\text{K} \times (4 \times 10^{-3}\text{ m})^2 = (25 + 17.5)^\circ\text{C} = 42.5^\circ\text{C}. <$$

COMMENTS: (1) Note that the assumed value of \bar{T} used to evaluate the thermophysical properties was reasonable. (2) We could have evaluated \bar{h}_{chip} by two other approaches. In one case the average coefficient is approximated as the arithmetic mean of local values at the leading and trailing edges of the chip.

$$\bar{h}_{\text{chip}} \approx [h_{x2}(x_2) + h_{x1}(x_1)] / 2 = 107\text{ W/m}^2\cdot\text{K}.$$

The exact approach is of the form

$$\bar{h}_{\text{chip}} \cdot \ell = \bar{h}_{x2} \cdot x_2 - \bar{h}_{x1} \cdot x_1$$

Recognizing that $h_x \sim x^{-0.15}$, it follows that

$$\bar{h}_x = \frac{1}{x} \int_0^x h_x \cdot dx = 1.176 h_x$$

and $\bar{h}_{\text{chip}} = 108\text{ W/m}^2\cdot\text{K}$. Why do results for the two approximate methods and the exact method compare so favorably?

PROBLEM 7.35

KNOWN: Air at atmospheric pressure and a temperature of 25°C in parallel flow at a velocity of 5 m/s over a 1-m long flat plate with a uniform heat flux of 1250 W/m².

FIND: (a) Plate surface temperature, $T_s(L)$, and local convection coefficient, $h_x(L)$, at the trailing edge, $x = L$, (b) Average temperature of the plate surface, \bar{T}_s , (c) Plot the variation of the plate surface temperature, $T_s(x)$, and the convection coefficient, $h_x(x)$, with distance on the same graph; explain key features of these distributions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Flow is fully turbulent, and (3) Constant properties.

PROPERTIES: Table A-4, Air (assume $T_f = 325$ K, 1 atm): $\nu = 18.76 \times 10^{-6}$ m²/s; $k = 0.0284$ W/m·K; $Pr = 0.703$.

ANALYSIS: (a) At the trailing edge, $x = L$, the convection rate equation is

$$q_s'' = q_{cv}'' = h_x(L) [T_s(L) - T_\infty] \quad (1)$$

where the local convection coefficient, assuming turbulent flow, follows from Eq. 7.46.

$$Nu_x = \frac{h_x x}{k} = 0.0308 Re_x^{4/5} Pr^{1/3} \quad (2)$$

With $x = L = 1$ m, find

$$Re_x = u_\infty L / \nu = 5 \text{ m/s} \times 1 \text{ m} / 18.76 \times 10^{-6} \text{ m}^2/\text{s} = 2.67 \times 10^5$$

$$h_x(L) = (0.0284 \text{ W/m} \cdot \text{K} / 1 \text{ m}) \times 0.0308 (2.67 \times 10^5)^{4/5} (0.703)^{1/3} = 17.1 \text{ W/m}^2 \cdot \text{K}$$

Substituting numerical values into Eq. (1),

$$T_s(L) = 25^\circ\text{C} + 1250 \text{ W/m}^2 / 17.1 \text{ W/m}^2 \cdot \text{K} = 98.3^\circ\text{C} \quad <$$

(b) The average surface temperature \bar{T}_s follows from the expression

$$\bar{T}_s - T_\infty = \frac{1}{L} \int_0^L (T_s - T_\infty) dx = \frac{q_s''}{L} \int_0^L \frac{x}{k Nu_x} dx \quad (3)$$

where Nu_x is given by Eq. (2). Using the *Integral* function in *IHT* as described in Comment (3) find

$$\bar{T}_s = 86.1^\circ\text{C} \quad <$$

(c) The variation of the plate surface temperature $T_s(x)$ and convection coefficient, $h_x(x)$, shown in the graph are calculated using Eqs. (1) and (2).

Continued

PROBLEM 7.35 (Cont.)

COMMENTS: (1) The properties for the correlation should be evaluated at $T_f = (\bar{T}_s + T_\infty)/2$.

From the foregoing analyses, $T_f = (86.1 + 25)^\circ/2 = 55.5^\circ\text{C} = 329\text{ K}$. Hence, the assumed value of 325 K was reasonable.

(2) The IHT code, excluding the input variables and air property functions, used to evaluate the integral of Eq. (3) and generate the graphs in part (c) is shown below.

```
/* Programming note: when using the INTEGRAL function, the value of the independent variable
must not be specified as an input variable. If done so, this error message will appear:
"Redefinition of a constant variable." */

// Turbulent flow correlation, Eq. 7.45, local values
Nu_x = 0.0308 * Re_x^0.8 * Pr^0.333
Nu_x = h_x * x / k
Re_x = u_inf * x / nu

// Plate temperatures
// Local
Ts_x = T_inf + q"s / h_x
// Average
Ts_avg - T_inf = q"s / L * INTEGRAL (y,x)
delT_avg = Ts_avg - T_inf
y = x / (k * Nu_x)
```

PROBLEM 7.36

KNOWN: Conditions for airflow over isothermal plate with optional unheated starting length.

FIND: (a) local coefficient, h_x , at leading and trailing edges with and without an unheated starting length, $\xi = 1$ m.

SCHEMATIC:

PROPERTIES: Table A.4, Air ($T_f = 325$ K, 1 atm): $\nu = 18.4 \times 10^{-6}$ m²/s, $Pr = 0.703$, $k = 0.0282$ W/m·K.

ANALYSIS: (a) The Reynolds number at $\xi = 1$ m is

$$Re_\xi = \frac{u_\infty \xi}{\nu} = \frac{2 \text{ m/s} \times 1 \text{ m}}{18.4 \times 10^{-6} \text{ m}^2/\text{s}} = 1.087 \times 10^5$$

If $Re_{x,c} = 5 \times 10^5$, flow is laminar over the entire plate (with or without the starting length). In general,

$$Nu_x = \frac{0.332 Re_x^{1/2} Pr^{1/3}}{\left[1 - (\xi/x)^{3/4}\right]^{1/3}} \quad (1)$$

$$h_x = \frac{(0.332 k Pr^{1/3}) Re_x^{1/2}}{x \left[1 - (\xi/x)^{3/4}\right]^{1/3}} = 0.00832 \text{ W/m}^2 \cdot \text{K} \frac{Re_x^{1/2}}{x \left[1 - (\xi/x)^{3/4}\right]^{1/3}}$$

With Unheated Starting Length: Leading edge ($x = 1$ m): $Re_x = Re_\xi$, $\xi/x = 1$, $h_x = \infty$ <

Trailing Edge ($x = 2$ m): $Re_x = 2 Re_\xi = 2.17 \times 10^5$, $\xi/x = 0.5$

$$h_x = 0.00832 \text{ W/m}^2 \cdot \text{K} \frac{(2.17 \times 10^5)^{1/2}}{2 \text{ m} \left[1 - (0.5)^{3/4}\right]^{1/3}} = 2.61 \text{ W/m}^2 \cdot \text{K} <$$

Without Unheated Starting Length: Leading edge ($x = 0$): $h_x = \infty$ <

Trailing edge ($x = 1$ m): $Re_x = 1.087 \times 10^5$

$$h_x = 0.00832 \text{ W/m}^2 \cdot \text{K} \frac{(1.087 \times 10^5)^{1/2}}{1 \text{ m}} = 2.74 \text{ W/m}^2 \cdot \text{K} <$$

(b) The average convection coefficient \bar{h}_L for the two cases in the schematic are, from Eq. 6.14,

Continued...

PROBLEM 7.36 (Cont.)

$$\bar{h}_L = \frac{1}{L} \int_0^L h_x(x) dx \quad (2)$$

where L is the x location at the end of the heated section. Substituting Eq. (1) into Eq. (2) and numerically integrating, the results are tabulated below:

ξ (m)	h_x (L)(W/m ² ·K)	\bar{h}_L (W/m ² ·K)
0	2.74	5.41
1	2.61	4.22

(c) The variation of the local convection coefficient over the plate, with and without the unheated starting length, using Eq. (1) is shown below. The abscissa is $x - \xi$.

COMMENTS: (1) When the velocity and thermal boundary layers grow simultaneously (*without starting length*), we expect the local and average coefficients to be larger than when the velocity boundary layer is thicker (*with starting length*).

(2) When $\xi = 0$, $\bar{h}_L = 2h_L$, when $\xi = 1$, $\bar{h}_L < 2h_L$. From Eq. (7.44), $\bar{h}_L = 4.25 \text{ W/m}^2 \cdot \text{K}$.

(3) The numerical integration of Eq. (2) was performed using the INTEGRAL (f,x) operation in IHT as shown in the Workspace below.

```
// Average Coefficient:
hbarL = 1 / (L - zeta) * INTEGRAL (hx,x)

// Local Coefficient With Unheated Starting Length:
hx = (k / x) * 0.332 * Rex^0.5 * Pr^0.3333 / (1 - (zeta / x)^(3/4))^(1/3)
Rex = uinf * x / nu

// Properties Tool - Air:
// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
nu = nu_T("Air",Tf) // Kinematic viscosity, m^2/s
k = k_T("Air",Tf) // Thermal conductivity, W/m·K
Pr = Pr_T("Air",Tf) // Prandtl number
Tf = 325 // Film temperature, K

// Assigned Variables:
uinf = 2 // Airstream velocity, m/s
x = 1 // Distance from leading edge, m
L = 2 // Full length of plate, m
zeta = 1 // Starting length, m
xzeta = x - zeta // Difference
```

PROBLEM 7.37

KNOWN: Cover plate dimensions and temperature for flat plate solar collector. Air flow conditions.

FIND: (a) Heat loss with simultaneous velocity and thermal boundary layer development, (b) Heat loss with unheated starting length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Boundary layer is not disturbed by roof-plate interface, (4) $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: Table A-4, Air ($T_f = 285.5\text{K}$, 1 atm): $\nu = 14.6 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0251 \text{ W/m}\cdot\text{K}$, $Pr = 0.71$.

ANALYSIS: (a) The Reynolds number for the plate of $L = 1\text{ m}$ is

$$Re_L = \frac{u_\infty L}{\nu} = \frac{2 \text{ m/s} \times 1 \text{ m}}{14.6 \times 10^{-6} \text{ m}^2/\text{s}} = 1.37 \times 10^5 < Re_{x,c}.$$

For laminar flow

$$\overline{Nu}_L = 0.664 Re_L^{1/2} Pr^{1/3} = 0.664 (1.37 \times 10^5)^{1/2} (0.71)^{1/3} = 219.2$$

$$q = \frac{k}{L} \overline{Nu}_L A_s (T_s - T_\infty) = \frac{0.0251 \text{ W/m}\cdot\text{K}}{1 \text{ m}} 219.2 (2 \text{ m}^2) 5^\circ\text{C} = 55 \text{ W.} \quad <$$

(b) The Reynolds number for the roof and collector of length $L = 3\text{ m}$ is

$$Re_L = \frac{2 \text{ m/s} \times 3 \text{ m}}{14.6 \times 10^{-6} \text{ m}^2/\text{s}} = 4.11 \times 10^5 < Re_{x,c}.$$

Hence, laminar boundary layer conditions exist throughout and the heat rate is

$$q = \int_{\xi}^L q'' dA = (T_s - T_\infty) 0.332 \left(\frac{u_\infty}{\nu} \right)^{1/2} Pr^{1/3} kW \int_{\xi}^L \frac{x^{-1/2} dx}{\left[1 - (\xi/x)^{3/4} \right]^{1/3}}$$

$$q = (5^\circ\text{C}) 0.332 \left(\frac{2 \text{ m/s}}{14.6 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{1/2} (0.71)^{1/3} 0.0251 \frac{\text{W}}{\text{m}\cdot\text{K}} 2 \text{ m} \int_{\xi}^L \frac{x^{-1/2} dx}{\left[1 - (\xi/x)^{3/4} \right]^{1/3}}$$

Using a numerical technique to evaluate the integral,

$$q = 27.50 \int_2^3 \frac{x^{-1/2} dx}{\left[1 - (2.0/x)^{3/4} \right]^{1/3}} = 27.50 \times 1.417 = 39 \text{ W} \quad <$$

COMMENTS: Values of \bar{h} with and without the unheated starting length are 3.9 and 5.5 $\text{W/m}^2\cdot\text{K}$. Prior development of the velocity boundary layer decreases \bar{h} .

PROBLEM 7.38

KNOWN: Surface dimensions for an array of 10 silicon chips. Maximum allowable chip temperature. Air flow conditions.

FIND: Maximum allowable chip electrical power (a) without and (b) with a turbulence promoter at the leading edge.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Film temperature of 52°C, (3) Negligible radiation, (4) Negligible heat loss through insulation, (5) Uniform heat flux at chip interface with air, (6)

$$Re_{x,c} = 5 \times 10^5.$$

PROPERTIES: Table A-4, Air ($T_f = 325\text{K}$, 1 atm): $\nu = 18.4 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0282 \text{ W/m}\cdot\text{K}$, $Pr = 0.703$.

ANALYSIS: $Re_L = u_\infty L / \nu = 40 \text{ m/s} \times 0.1 \text{ m} / 18.4 \times 10^{-6} \text{ m}^2/\text{s} = 2.174 \times 10^5$. Hence, flow is laminar over all chips without the promoter.

(a) For *laminar flow*, the minimum h_x exists on the last chip. Approximating the average coefficient for Chip 10 as the local coefficient at $x = 95 \text{ mm}$, $\bar{h}_{10} = h_{x=0.095\text{m}}$.

$$\bar{h}_{10} = 0.453 \frac{k}{x} Re_x^{1/2} Pr^{1/3}$$

$$Re_x = \frac{u_\infty x}{\nu} = \frac{40 \text{ m/s} \times 0.095 \text{ m}}{18.4 \times 10^{-6} \text{ m}^2/\text{s}} = 2.065 \times 10^5$$

$$\bar{h}_{10} = 0.453 \frac{0.0282 \text{ W/m}\cdot\text{K}}{0.095} \left(2.065 \times 10^5 \right)^{1/2} (0.703)^{1/3} = 54.3 \text{ W/m}^2 \cdot \text{K}$$

$$q_{10} = \bar{h}_{10} A (T_s - T_\infty) = 54.3 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (0.01 \text{ m})^2 (80 - 24)^\circ \text{C} = 0.30 \text{ W}.$$

Hence, if all chips are to dissipate the same power and T_s is not to exceed 80°C.

$$q_{\max} = 0.30 \text{ W}. \quad <$$

(b) For *turbulent flow*,

$$\bar{h}_{10} = 0.0308 \frac{k}{x} Re_x^{4/5} Pr^{1/3} = 0.0308 \frac{0.0282 \text{ W/m}\cdot\text{K}}{0.095 \text{ m}} \left(2.065 \times 10^5 \right)^{4/5} (0.703)^{1/3} = 145 \text{ W/m}^2 \cdot \text{K}$$

$$q_{10} = \bar{h}_{10} A (T_s - T_\infty) = 145 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (0.01 \text{ m})^2 (80 - 24)^\circ \text{C} = 0.81 \text{ W}.$$

Hence, $q_{\max} = 0.81 \text{ W}.$ $<$

COMMENTS: It is far better to orient array normal to the air flow. Since $\bar{h}_1 > \bar{h}_{10}$, more heat could be dissipated per chip, and the same heat could be dissipated from each chip.

PROBLEM 7.39

KNOWN: Dimensions and maximum allowable temperature of a silicon chip. Air flow conditions.

FIND: Maximum allowable power with or without unheated starting length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) $T_f = 52^\circ\text{C}$, (3) Negligible radiation, (4) Negligible heat loss through insulation, (5) Uniform heat flux at chip-air interface, (6) $\text{Re}_{x,c} = 5 \times 10^5$.

PROPERTIES: Table A-4, Air ($T_f = 325\text{K}$, 1 atm): $\nu = 18.41 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0282 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.703$.

ANALYSIS: For uniform heat flux, maximum T_s corresponds to minimum h_x . Without unheated starting length,

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{20 \text{ m/s} \times 0.01 \text{ m}}{18.41 \times 10^{-6} \text{ m}^2/\text{s}} = 10,864.$$

With the unheated starting length, $L = 0.03 \text{ m}$, $\text{Re}_L = 32,591$. Hence, the flow is laminar in both cases and the minimum h_x occurs at the trailing edge ($x = L$).

Without unheated starting length,

$$h_L = \frac{k}{L} 0.453 \text{Re}_L^{1/2} \text{Pr}^{1/3} = \frac{0.0282 \text{ W/m}\cdot\text{K}}{0.01 \text{ m}} 0.453 (10,864)^{1/2} (0.703)^{1/3}$$

$$h_L = 118 \text{ W/m}^2 \cdot \text{K}$$

$$q''(L) = h_L (T_s - T_\infty) = 118 \text{ W/m}^2 \cdot \text{K} (80 - 24)^\circ\text{C} = 6630 \text{ W/m}^2$$

$$q_{\max} = A_s q'' = (10^{-2} \text{ m})^2 6630 \text{ W/m}^2 = 0.66 \text{ W}. \quad <$$

With the unheated starting length,

$$h_L = \frac{k}{L} 0.453 \frac{\text{Re}_L^{1/2} \text{Pr}^{1/3}}{\left[1 - (\xi/L)^{3/4}\right]^{1/3}} = \frac{0.0282 \text{ W/m}\cdot\text{K}}{0.03 \text{ m}} 0.453 \frac{(32,591)^{1/2} (0.703)^{1/3}}{\left[1 - (0.02/0.03)^{3/4}\right]^{1/3}}$$

$$h_L = 107 \text{ W/m}^2 \cdot \text{K}$$

$$q''(L) = h_L (T_s - T_\infty) = 107 \text{ W/m}^2 \cdot \text{K} (80 - 24)^\circ\text{C} = 6013 \text{ W/m}^2$$

$$q_{\max} = A_s q'' = 10^{-4} \text{ m}^2 \times 6013 \text{ W/m}^2 = 0.60 \text{ W}. \quad <$$

COMMENTS: Prior velocity boundary layer development on the unheated starting section decreases h_x , although the effect diminishes with increasing x .

PROBLEM 7.40

KNOWN: Experimental apparatus providing nearly uniform airstream over a flat *test plate*. Temperature history of the pre-heated plate for airstream velocities of 3 and 9 m/s were fitted to a fourth-order polynomial.

FIND: (a) Convection coefficient for the two cases assuming the plate behaves as a spacewise isothermal object and (b) Coefficients C and m for a correlation of the form $\overline{Nu}_L = C Re^m Pr^{1/3}$; compare result with a standard-plate correlation and comment on the goodness of the comparison; explain any differences.

SCHEMATIC:

ASSUMPTIONS: (1) Airstream over the *test plate* approximates parallel flow over a flat plate, (2) Plate is spacewise isothermal, (3) Negligible radiation exchange between plate and surroundings, (4) Constant properties, and (5) Negligible heat loss from the bottom surface or edges of the test plate.

PROPERTIES: Table A.4, Air ($T_f = (T_s + T_\infty)/2 \approx 310$ K, 1 atm): $k_a = 0.0269$ W/m·K, $\nu = 1.669 \times 10^{-5}$ m²/s, $Pr = 0.706$. Test plate (Given): $\rho = 2770$ kg/m³, $c_p = 875$ J/kg·K, $k = 177$ W/m·K.

ANALYSIS: (a) Using the lumped-capacitance method, the energy balance on the plate is

$$-\bar{h}_L A_s [T_s(t) - T_\infty] = \rho V c_p \frac{dT}{dt} \quad (1)$$

and the average convection coefficient can be determined from the temperature history, $T_s(t)$,

$$\bar{h}_L = \frac{\rho V c_p}{A_s} \frac{(dT/dt)}{T_s(t) - T_\infty} \quad (2)$$

where the temperature-time derivative is

$$\frac{dT_s}{dt} = b + 2ct + 3dt^2 + 4et^3 \quad (3)$$

The temperature time history plotted below shows the experimental behavior of the observed data.

Continued...

PROBLEM 7.40 (Cont.)

Consider now the integrated form of the energy balance, Eq. (5.6), expressed as

$$\ln \frac{T_s(t) - T_\infty}{T_i - T_\infty} = - \left(\frac{\bar{h}_L A_s}{\rho V c} \right) t \quad (4)$$

If we were to plot the LHS vs t , the slope of the curve would be proportional to \bar{h}_L . Using IHT, plots were generated of \bar{h}_L vs. T_s , Eq. (1), and $\ln \left[(T_s(t) - T_\infty) / (T_i - T_\infty) \right]$ vs. t , Eq. (4). From the latter plot, recognize that the regions where the slope is constant corresponds to early times (≤ 100 s when $u_\infty = 3$ m/s and ≤ 50 s when $u_\infty = 5$ m/s).

Selecting two elapsed times at which to evaluate \bar{h}_L , the following results were obtained

u_∞ (m/s)	t (s)	$T_s(t)$ (°C)	\bar{h}_L (W/m ² ·K)	\overline{Nu}_L	Re_L
3	100	44.77	30.81	152.4	2.39×10^4
9	50	45.80	56.7	280.4	7.17×10^4

where the dimensionless parameters are evaluated as

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k_a} \quad Re_L = \frac{u_\infty L}{\nu} \quad (5,6)$$

where k_a , ν are thermophysical properties of the airstream.

(b) Using the above pairs of \overline{Nu}_L and Re_L , C and m in the correlation can be evaluated,

$$\overline{Nu}_L = C Re_L^m Pr^{1/3} \quad (7)$$

$$152.4 = C(2.39 \times 10^4)^m (0.706)^{1/3}$$

$$280.4 = C(7.17 \times 10^4)^m (0.706)^{1/3}$$

Solving, find

$$C = 0.633 \quad m = 0.555 \quad (8,9) <$$

Continued...

PROBLEM 7.40 (Cont.)

The plot below compares the experimental correlation ($C = 0.633$, $m = 0.555$) with those for laminar flow ($C = 0.664$, $m = 0.5$) and fully turbulent flow ($C = 0.037$, $m = 0.8$). The experimental correlation yields \overline{Nu}_L values which are 25% higher than for the correlation. The most likely explanation for this unexpected trend is that the airstream reaching the plate is not parallel, but with a slight impingement effect and/or the flow is very highly turbulent at the leading edge.

COMMENTS: (1) A more extensive analysis of the experimental observations would involve determining \overline{Nu}_L for the full range of elapsed time (rather than at two selected times) and using a fitting routine to determine values for C and m .

PROBLEM 7.41

KNOWN: Cylinder diameter and surface temperature. Temperature and velocity of fluids in cross flow.

FIND: (a) Rate of heat transfer per unit length for the fluids: atmospheric air and saturated water, and engine oil, for velocity $V = 5$ m/s, using the Churchill-Bernstein correlation, and (b) Compute and plot q' as a function of the fluid velocity $0.5 \leq V \leq 10$ m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform cylinder surface temperature.

PROPERTIES: Table A.4, Air ($T_f = 308$ K, 1 atm): $\nu = 16.69 \times 10^{-6}$ m²/s, $k = 0.0269$ W/m·K, $Pr = 0.706$; Table A.6, Saturated Water ($T_f = 308$ K): $\rho = 994$ kg/m³, $\mu = 725 \times 10^{-6}$ N·s/m², $k = 0.625$ W/m·K, $Pr = 4.85$; Table A.5, Engine Oil ($T_f = 308$ K): $\nu = 340 \times 10^{-6}$ m²/s, $k = 0.145$ W/m·K, $Pr = 4000$.

ANALYSIS: (a) For each fluid, calculate the Reynolds number and use the Churchill-Bernstein correlation, Eq. 7.54,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5}$$

Fluid: Atmospheric Air

$$Re_D = \frac{VD}{\nu} = \frac{(5 \text{ m/s})(0.01 \text{ m})}{16.69 \times 10^{-6} \text{ m}^2/\text{s}} = 2996$$

$$\overline{Nu}_D = 0.3 + \frac{0.62(2996)^{1/2} (0.706)^{1/3}}{\left[1 + (0.4/0.706)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{2996}{282,000}\right)^{5/8}\right]^{4/5} = 28.1$$

$$\bar{h} = \frac{k}{D} \overline{Nu}_D = \frac{0.0269 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} 28.1 = 75.5 \text{ W/m}^2 \cdot \text{K}$$

$$q' = \bar{h} \pi D (T_s - T_\infty) = 75.5 \text{ W/m}^2 \cdot \text{K} \pi (0.01 \text{ m}) (50 - 20)^\circ \text{C} = 71.1 \text{ W/m}$$

<

Fluid: Saturated Water

$$Re_D = \frac{VD}{\nu} = \frac{(5 \text{ m/s})(0.01 \text{ m})}{725 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 / 994 \text{ kg/m}^3} = 68,552$$

$$\overline{Nu}_D = 0.3 + \frac{0.62(68,552)^{1/2} (4.85)^{1/3}}{\left[1 + (0.4/4.85)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{68,552}{282,000}\right)^{5/8}\right]^{4/5} = 347$$

Continued...

PROBLEM 7.41 (Cont.)

$$\bar{h} = \frac{k}{D} \overline{\text{Nu}}_D = \frac{0.625 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} 347 = 21,690 \text{ W/m}^2 \cdot \text{K} \quad q' = 20,438 \text{ W/m} \quad <$$

Fluid: Engine Oil

$$\text{Re}_D = \frac{VD}{\nu} = \frac{(5 \text{ m/s})(0.01 \text{ m})}{340 \times 10^{-6} \text{ m}^2/\text{s}} = 147$$

$$\overline{\text{Nu}}_D = 0.3 + \frac{0.62(147)^{1/2}(4000)^{1/3}}{\left[1 + (0.4/4000)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{147}{282,000}\right)^{5/8}\right]^{4/5} = 120$$

$$\bar{h} = \frac{k}{D} \overline{\text{Nu}}_D = \frac{0.145 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} 120 = 1740 \text{ W/m}^2 \cdot \text{K} \quad q' = 1639 \text{ W/m} \quad <$$

(b) Using the *IHT Correlations Tool, External Flow, Cylinder*, along with the *Properties Tool* for each of the fluids, the heat rates, q' , were calculated for the range $0.5 \leq V \leq 10 \text{ m/s}$. Note the q' scale multipliers for the air and oil fluids which permit easy comparison of the three curves.

COMMENTS: (1) Note the inapplicability of the Zukauskas relation, Eq. 7.53, since $\text{Pr}_{\text{oil}} > 500$.

(2) In the plot above, recognize that the heat rate for the water is more than 10 times that with oil and 300 times that with air. How do changes in the velocity affect the heat rates for each of the fluids?

PROBLEM 7.42

KNOWN: Conditions associated with air in cross flow over a pipe.

FIND: (a) Drag force per unit length of pipe, (b) Heat transfer per unit length of pipe.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform cylinder surface temperature, (3) Negligible radiation effects.

PROPERTIES: Table A-4, Air ($T_f = 335 \text{ K}$, 1 atm): $\nu = 19.31 \times 10^{-6} \text{ m}^2/\text{s}$, $\rho = 1.048 \text{ kg/m}^3$, $k = 0.0288 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.702$.

ANALYSIS: (a) From the definition of the drag coefficient with $A_f = DL$, find

$$F_D = C_D A_f \frac{\rho V^2}{2}$$

$$F'_D = C_D D \frac{\rho V^2}{2}$$

With

$$\text{Re}_D = \frac{VD}{\nu} = \frac{15 \text{ m/s} \times (0.025 \text{ m})}{19.31 \times 10^{-6} \text{ m}^2/\text{s}} = 1.942 \times 10^4$$

from Fig. 7.8, $C_D \approx 1.1$. Hence

$$F'_D = 1.1(0.025 \text{ m}) 1.048 \text{ kg/m}^3 (15 \text{ m/s})^2 / 2 = 3.24 \text{ N/m.} \quad <$$

(b) Using Hilpert's relation, with $C = 0.193$ and $m = 0.618$ from Table 7.2,

$$\bar{h} = \frac{k}{D} \text{Re}_D^m \text{Pr}^{1/3} = \frac{0.0288 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} \times 0.193 (1.942 \times 10^4)^{0.618} (0.702)^{1/3}$$

$$\bar{h} = 88 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the heat rate per unit length is

$$q' = \bar{h}(\pi D) (T_s - T_\infty) = 88 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.025 \text{ m}) (100 - 25)^\circ\text{C} = 520 \text{ W/m.} \quad <$$

COMMENTS: Using the Zukauskas correlation and evaluating properties at T_∞ ($\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0261 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.707$), but with $\text{Pr}_s = 0.695$ at T_s ,

$$\bar{h} = \frac{0.0261}{0.025} 0.26 \left(\frac{15 \times 0.025}{15.71 \times 10^{-6}} \right)^{0.6} (0.707)^{0.37} (0.707/0.695)^{1/4} = 102 \text{ W/m}^2 \cdot \text{K}.$$

This result agrees with that obtained from Hilpert's relation to within the uncertainty normally associated with convection correlations.

PROBLEM 7.43

KNOWN: Initial temperature, power dissipation, diameter, and properties of heating element. Velocity and temperature of air in cross flow.

FIND: (a) Steady-state temperature, (b) Time to come within 10°C of steady-state temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform heater temperature, (2) Negligible radiation.

PROPERTIES: Table A.4, air (assume $T_f \approx 450$ K): $\nu = 32.39 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0373 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.686$.

ANALYSIS: (a) Performing an energy balance for steady-state conditions, we obtain

$$q'_{\text{conv}} = \bar{h}(\pi D)(T - T_{\infty}) = P'_{\text{elec}} = 1000 \text{ W/m}$$

With

$$\text{Re}_D = \frac{VD}{\nu} = \frac{(10 \text{ m/s})(0.01 \text{ m})}{32.39 \times 10^{-6} \text{ m}^2/\text{s}} = 3,087$$

the Churchill and Bernstein correlation, Eq. 7.54, yields

$$\begin{aligned} \overline{\text{Nu}}_D &= 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5} \\ \overline{\text{Nu}}_D &= 0.3 + \frac{0.62(3087)^{1/2} (0.686)^{1/3}}{\left[1 + (0.4/0.686)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{3087}{282,000}\right)^{5/8}\right]^{4/5} = 28.2 \\ \bar{h} &= \frac{k}{D} \overline{\text{Nu}}_D = \frac{0.0373 \text{ W/m}\cdot\text{K}}{0.010 \text{ m}} 28.2 = 105.2 \text{ W/m}^2\cdot\text{K} \end{aligned}$$

Hence, the steady-state temperature is

$$T = T_{\infty} + \frac{P'_{\text{elec}}}{\pi D \bar{h}} = 300 \text{ K} + \frac{1000 \text{ W/m}}{\pi (0.01 \text{ m}) 105.2 \text{ W/m}^2\cdot\text{K}} = 603 \text{ K} \quad <$$

(b) With $\text{Bi} = \bar{h}r_0/k = 105.2 \text{ W/m}^2\cdot\text{K}(0.005 \text{ m})/240 \text{ W/m}\cdot\text{K} = 0.0022$, a lumped capacitance analysis may be performed. The time response of the heater is given by Eq. 5.25, which, for $T_i = T_{\infty}$, reduces to

$$T = T_{\infty} + (b/a)[1 - \exp(-at)]$$

Continued...

PROBLEM 7.43 (Cont.)

where $a = 4\bar{h}/D\rho c_p = (4 \times 105.2 \text{ W/m}^2 \cdot \text{K}) / (0.01 \text{ m} \times 2700 \text{ kg/m}^3 \times 900 \text{ J/kg} \cdot \text{K}) = 0.0173 \text{ s}^{-1}$ and $b/a = P'_{\text{elec}} / \pi D \bar{h} = 1000 \text{ W/m} / \pi (0.01 \text{ m} \times 105.2 \text{ W/m}^2 \cdot \text{K}) = 302.6 \text{ K}$. Hence,

$$[1 - \exp(-0.0173t)] = \frac{(593 - 300) \text{ K}}{302.6 \text{ K}} = 0.968$$

$$t \approx 200 \text{ s}$$

<

COMMENTS: (1) For $T = 603 \text{ K}$ and a representative emissivity of $\varepsilon = 0.8$, net radiation exchange between the heater and surroundings at $T_{\text{sur}} = T_{\infty} = 300 \text{ K}$ would be $q'_{\text{rad}} = \varepsilon \sigma (\pi D) (T^4 - T_{\text{sur}}^4) = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (\pi \times 0.01 \text{ m})(603^4 - 300^4) \text{ K}^4 = 177 \text{ W/m}$. Hence, although small, radiation exchange is not negligible. The effects of radiation are considered in Problem 7.46.

(2) The assumed value of T_f is very close to the actual value, rendering the selected air properties accurate.

PROBLEM 7.44

KNOWN: Initial temperature, power dissipation, diameter, and properties of a heating element. Velocity and temperature of air in cross flow. Temperature of surroundings.

FIND: (a) Steady-state temperature, (b) Time to come within 10°C of steady-state temperature, (c) Variation of power dissipation required to maintain a fixed heater temperature of 275°C over a range of velocities.

SCHEMATIC:

ASSUMPTIONS: Uniform heater surface temperature.

ANALYSIS: (a) Performing an energy balance for steady-state conditions, we obtain

$$q'_{\text{conv}} + q'_{\text{rad}} = P'_{\text{elec}}$$

$$\bar{h}(\pi D)(T - T_\infty) + \varepsilon\sigma(\pi D)(T^4 - T_{\text{sur}}^4) = P'_{\text{elec}}$$

$$(\pi \times 0.01 \text{ m}) \left[\bar{h}(T - 300) \text{ K} + 0.8(5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4)(T^4 - 300^4) \text{ K}^4 \right] = 1000 \text{ W/m}$$

Using the *IHT Energy Balance Model* for an *Isothermal Solid Cylinder* with the *Correlations Tool Pad* for a *Cylinder in Crossflow* and the *Properties Tool Pad* for *Air*, we obtain

$$T = 562.4 \text{ K}$$

where $\bar{h} = 105.4 \text{ W/m}^2 \cdot \text{K}$, $h_r = 15.9 \text{ W/m}^2 \cdot \text{K}$, $q'_{\text{conv}} = 868.8 \text{ W/m}$, and $q'_{\text{rad}} = 131.2 \text{ W/m}$.

(b) With $\text{Bi} = (\bar{h} + h_r)r_0/k = (121.3 \text{ W/m}^2 \cdot \text{K})0.005 \text{ m}/240 \text{ W/m} \cdot \text{K} = 0.0025$, the transient behavior may be analyzed using the lumped capacitance method. Using the *IHT Lumped Capacitance Model* to perform the numerical integration, the following temperature histories were obtained.

Continued...

PROBLEM 7.44 (Cont.)

The agreement between predictions with and without radiation for $t < 50$ s implies negligible radiation. However, as the heater temperature increases with time, radiation becomes significant, yielding a reduced heater temperature. Steady-state temperatures correspond to 562.4 K and 602.8 K, with and without radiation, respectively. The time required for the heater to reach 552.4 K (with radiation) is $t \approx 155$ s.

(c) If the heater temperature is to be maintained at a fixed value in the face of velocity excursions, provision must be made for adjusting the heater power. Using the *Explore* and *Graph* options of IHT with the model of part (a), the following results were obtained.

For $T = 275^\circ\text{C} = 548$ K, the controller would compensate for velocity reductions from 10 to 5 m/s by reducing the power from approximately 935 to 690 W/m.

COMMENTS: Although convection heat transfer substantially exceeds radiation heat transfer, radiation is not negligible and should be included in the analysis. If it is neglected, $T = 603$ K would be predicted for $P'_{elec} = 1000$ W/m, in contrast to 562 K from the results of part (a).

PROBLEM 7.45

KNOWN: Pin fin of 10 mm diameter dissipates 30 W by forced convection in cross-flow of air with $Re_D = 4000$.

FIND: Fin heat rate if diameter is doubled while all conditions remain the same.

SCHEMATIC:

ASSUMPTIONS: (1) Pin behaves as infinitely long fin, (2) Conditions of flow, as well as base and air temperatures, remain the same for both situations, (3) Negligible radiation heat transfer.

ANALYSIS: For an infinitely long pin fin, the fin heat rate is

$$q_f = q_{conv} = (\bar{h} P k A_c)^{1/2} \theta_b$$

where $P = \pi D$ and $A_c = \pi D^2/4$. Hence,

$$q_{conv} \sim (\bar{h} \cdot D \cdot D^2)^{1/2}.$$

For forced convection cross-flow over a cylinder, an appropriate correlation for estimating the dependence of \bar{h} on the diameter is

$$\overline{Nu}_D = \frac{\bar{h} D}{k} = C Re_D^m Pr^{1/3} = C \left(\frac{VD}{\nu} \right)^m Pr^{1/3}.$$

From Table 7.2 for $Re_D = 4000$, find $m = 0.466$ and

$$\bar{h} \sim D^{-1} (D)^{0.466} = D^{-0.534}.$$

It follows that

$$q_{conv} \sim (D^{-0.534} \cdot D \cdot D^2)^{1/2} = D^{1.23}.$$

Hence, with $q_1 \rightarrow D_1$ (10 mm) and $q_2 \rightarrow D_2$ (20 mm), find

$$q_2 = q_1 \left(\frac{D_2}{D_1} \right)^{1.23} = 30 \text{ W} \left(\frac{20}{10} \right)^{1.23} = 70.4 \text{ W.} \quad <$$

COMMENTS: The effect of doubling the diameter, with all other conditions remaining the same, is to increase the fin heat rate by a factor of 2.35. The effect is nearly linear, with enhancements due to the increase in surface and cross-sectional areas ($D^{1.5}$) exceeding the attenuation due to a decrease in the heat transfer coefficient ($D^{-0.267}$). Note that, with increasing Reynolds number, the exponent m increases and there is greater heat transfer enhancement due to increasing the diameter.

PROBLEM 7.46

KNOWN: Pin fin installed on a surface with prescribed heat rate and temperature.

FIND: (a) Maximum heat removal rate possible, (b) Length of the fin, (c) Effectiveness, ϵ_f , (d) Percentage increase in heat rate from surface due to fin.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Conditions over A_s are uniform for both situations, (3) Conditions over fin length are uniform, (4) Flow over pin fin approximates cross-flow.

PROPERTIES: Table A-4, Air ($T_f = (T_\infty + T_s)/2 = (27 + 127)^\circ\text{C}/2 = 350\text{ K}$): $\nu = 20.92 \times 10^{-6}\text{ m}^2/\text{s}$, $k = 30.0 \times 10^{-3}\text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.700$. Table A-1, SS AISI304 ($\bar{T} = T_f = 350\text{ K}$): $k = 15.8\text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) Maximum heat rate from fin occurs when fin is infinitely long,

$$q_f = M = (\bar{h} P k A_c)^{1/2} \theta_b \quad (1)$$

from Eq. 3.80. Estimate convection heat transfer coefficient for cross-flow over cylinder,

$$\text{Re}_D = \frac{VD}{\nu} = 5\text{ m/s} \times 0.005\text{ m} / 20.92 \times 10^{-6}\text{ m}^2/\text{s} = 1195.$$

Using the Hilpert correlation, Eq. 7.55, with Table 7.2, find

$$\bar{h} = \frac{k}{D} \text{CRe}_D^m \text{Pr}^n = (0.030\text{ W/m}\cdot\text{K} / 0.005\text{ m}) (0.683)(1195)^{0.466} (0.700)^{1/3} = 98.9\text{ W/m}^2\cdot\text{K}$$

From Eq. (1), with $P = \pi D$, $A_c = \pi D^2/4$, and $\theta_b = T_s - T_\infty$, find

$$q_f = \left(98.9\text{ W/m}^2\cdot\text{K} \times \pi (0.005\text{ m}) \times 15.8\text{ W/m}\cdot\text{K} \times \pi (0.005\text{ m})^2 / 4 \right)^{1/2} (127 - 27)\text{ K} = 2.20\text{ W}. <$$

(b) From Example 3.9, $L \approx L_\infty = 2.65(kA_c/hP)^{1/2}$. Hence,

$$L \approx L_\infty = 2.65 \left[15.8\text{ W/m}\cdot\text{K} \times \pi (0.005\text{ m})^2 / 4 / 98.9\text{ W/m}^2\cdot\text{K} \times \pi (0.005\text{ m}) \right]^{1/2} = 37.4\text{ mm}. <$$

(c) From Eq. 3.81, with h_s used for the base area A_s , the effectiveness is

$$\epsilon_f = \frac{q_f}{h_s A_{c,b} \theta_b} = \frac{q_f}{q_{wo}} \frac{A_s}{A_{c,b}} = \frac{2.2\text{ W}}{0.5\text{ W}} \cdot \frac{(0.020 \times 0.020)\text{ m}^2}{\pi (0.005\text{ m})^2 / 4} = 89.6 <$$

where $h_s = q_{wo} / A_s \theta_b$.

(d) The percentage increase in heat rate with the installed fin (w) is

$$\frac{q_w - q_{wo}}{q_{wo}} \times 100 = \left(\left[q_f + h_s \left(A_s - \pi D^2 / 4 \right) (T_s - T_\infty) \right] - q_{wo} \right) \times 100 / q_{wo}$$

$$\Delta q/q = \left\{ \left[2.2\text{ W} + 12.5\text{ W/m}^2\cdot\text{K} \left([0.02\text{ m}]^2 - (\pi/4)(0.005\text{ m})^2 \right) 100\text{ K} - 0.5\text{ W} \right] \right\} \times 100 / 0.5\text{ W}$$

$$\Delta q/q = 435\%. <$$

PROBLEM 7.47

KNOWN: Dimensions of chip and pin fin. Chip temperature. Free stream velocity and temperature of air coolant.

FIND: (a) Average pin convection coefficient, (b) Pin heat transfer rate, (c) Total heat rate, (d) Effect of velocity and pin diameter on total heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in pin, (3) Constant properties, (4) Convection coefficients on pin surface (tip and side) and chip surface correspond to single cylinder in cross flow, (5) Negligible radiation.

PROPERTIES: Table A.1, Copper (350 K): $k = 399 \text{ W/m}\cdot\text{K}$; Table A.4, Air ($T_f \approx 325 \text{ K}$, 1 atm): $\nu = 18.41 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0282 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.704$.

ANALYSIS: (a) With $V = 10 \text{ m/s}$ and $D = 0.002 \text{ m}$,

$$\text{Re}_D = \frac{VD}{\nu} = \frac{10 \text{ m/s} \times 0.002 \text{ m}}{18.41 \times 10^{-6} \text{ m}^2/\text{s}} = 1087$$

Using the Churchill and Bernstein correlations, Eq. (7.54),

$$\overline{\text{Nu}}_D = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5} = 16.7$$

$$\bar{h} = (\overline{\text{Nu}}_D k/D) = (16.7 \times 0.0282 \text{ W/m}\cdot\text{K} / 0.002 \text{ m}) = 235 \text{ W/m}^2 \cdot \text{K} \quad <$$

(b) For the fin with tip convection and

$$M = \left(\bar{h} \pi D k \pi D^2 / 4 \right)^{1/2} \theta_b = (\pi/2) \left[235 \text{ W/m}^2 \cdot \text{K} (0.002 \text{ m})^3 399 \text{ W/m}\cdot\text{K} \right]^{1/2} 50 \text{ K} = 2.15 \text{ W}$$

$$m = (\bar{h} P / k A_c)^{1/2} = (4 \times 235 \text{ W/m}^2 \cdot \text{K} / 399 \text{ W/m}\cdot\text{K} \times 0.002 \text{ m})^{1/2} = 34.3 \text{ m}^{-1}$$

$$mL = 34.3 \text{ m}^{-1} (0.012 \text{ m}) = 0.412$$

$$(\bar{h}/mk) = (235 \text{ W/m}^2 \cdot \text{K} / 34.3 \text{ m}^{-1} \times 399 \text{ W/m}\cdot\text{K}) = 0.0172.$$

The fin heat rate is

$$q_f = M \frac{\sinh mL + (\bar{h}/mk) \cosh mL}{\cosh mL + (\bar{h}/mk) \sinh mL} = 0.868 \text{ W} \quad <$$

Continued...

PROBLEM 7.47 (Cont.)

(c) The total heat rate is that from the base and through the fin,

$$q = q_b + q_f = \bar{h} \left(W^2 - \pi D^2 / 4 \right) \theta_b + q_f = (0.151 + 0.868) W = 1.019 W .$$

<

(d) Using the IHT Extended Surface Model for a Pin Fin with the Correlations Tool Pad for a Cylinder in crossflow and Properties Tool Pad for Air, the following results were generated.

Clearly, there is significant benefit associated with increasing V which increases the convection coefficient and the total heat rate. Although the convection coefficient decreases with increasing D, the increase in the total heat transfer surface area is sufficient to yield an increase in q with increasing D. The maximum heat rate is $q = 2.77 \text{ W}$ for $V = 40 \text{ m/s}$ and $D = 4 \text{ mm}$.

COMMENTS: Radiation effects should be negligible, although tip and base convection coefficients will differ from those calculated in parts (a) and (d).

PROBLEM 7.48

KNOWN: Diameter, resistivity, thermal conductivity and emissivity of Nichrome wire. Electrical current. Temperature of air flow and surroundings. Velocity of air flow.

FIND: (a) Surface and centerline temperatures of the wire, (b) Effect of flow velocity and electric current on temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Radiation exchange with large surroundings, (3) Constant Nichrome properties, (4) Uniform surface temperature.

PROPERTIES: Prescribed, Nichrome: $k = 25 \text{ W/m}\cdot\text{K}$, $\rho_e = 10^{-6} \Omega\cdot\text{m}$, $\epsilon = 0.2$. Table A-4, air ($T_f \approx 800\text{K}$: $k_a = 0.057 \text{ W/m}\cdot\text{K}$, $\nu = 8.5 \times 10^{-5} \text{ m}^2/\text{s}$, $\text{Pr} = 0.71$).

ANALYSIS: (a) The surface temperature may be obtained from Eq. 3.55, with $\bar{h} = \bar{h}_c + h_r$ and

$$\dot{q} = I^2 R_e / \forall = I^2 \rho_e / A_c^2 = I^2 \rho_e / (\pi D^2 / 4)^2 = 1.013 \times 10^9 \text{ W/m}^3.$$

$$T_s = T_\infty + \frac{\dot{q}(D/2)}{2(\bar{h}_c + h_r)} \quad (1)$$

The convection coefficient is obtained from the Churchill and Bernstein correlation

$$\bar{h}_c = \frac{k_a}{D} \left\{ 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{[1 + (0.4/\text{Pr})^{2/3}]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5} \right\} = 230 \text{ W/m}^2\cdot\text{K}$$

where $\text{Re}_D = VD/\nu = 58.8$, and the radiation coefficient is obtained from Eq. 1.9

$$h_r = \epsilon \sigma (T_s + T_{\text{sur}})(T_s^2 + T_{\text{sur}}^2) \quad (2)$$

From an iterative solution of Eqs. (1) and (2), we obtain

$$T_s \approx 1285\text{K} = 1012^\circ\text{C} \quad <$$

From Eq. 3.53, the centerline temperature is

$$T_o = \frac{\dot{q}(D/2)^2}{4k} + T_s = \frac{1.013 \times 10^9 \text{ W/m}^3 (0.0005\text{m})^2}{100 \text{ W/m}\cdot\text{K}} + 1012^\circ\text{C} \approx 1014^\circ\text{C} \quad <$$

The centerline temperature is only approximately 2°C larger than the surface temperature, and the wire may be assumed to be isothermal.

Continued

PROBLEM 7.48 (Cont.)

(b) Over the range $1 \leq V < 100$ m/s for $I = 25$ A, \bar{h}_c varies from approximately $114 \text{ W/m}^2 \cdot \text{K}$ to $1050 \text{ W/m}^2 \cdot \text{K}$, while h_r varies from approximately $69 \text{ W/m}^2 \cdot \text{K}$ to $4 \text{ W/m}^2 \cdot \text{K}$. The effect on the surface temperature is shown below.

Maximum and minimum values of $T_s = 1433^\circ\text{C}$ and $T_s = 290^\circ\text{C}$ are associated with the smallest and largest velocities respectively, while the difference between the centerline and surface temperatures remains at $(T_0 - T_s) \approx 2^\circ\text{C}$.

For $V = 5$ m/s, the effect on T_s of varying the current over the range from 1 to 30 A is shown below.

From a value of $T_s \approx 52^\circ\text{C}$ at 1 A, T_s increases to 1320°C at 30 A. Over this range the temperature difference $(T_0 - T_s)$ increases from approximately 0.01°C to 3°C .

COMMENTS: (1) The radiation coefficient for the conditions of Part (a) is $h_r = 32 \text{ W/m}^2 \cdot \text{K}$, which is approximately 1/8 of the total coefficient \bar{h} . Hence, except for small values of V less than approximately 5 m/s, radiation is negligible compared with convection. (2) The small wire diameter and large thermal conductivity are responsible for maintaining nearly isothermal conditions within the wire. (3) The calculations of Part (b) were performed using the IHT solver with the function $T_f = T_{\text{fluid_avg}}(T_s, T_{\text{inf}})$ used to account for the effect of temperature on the air properties.

PROBLEM 7.49

KNOWN: Temperature and heat dissipation in a wire of diameter D .

FIND: (a) Expression for flow velocity over wire, (b) Velocity of airstream for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform wire temperature, (3) Negligible radiation.

PROPERTIES: Table A-4, Air ($T_\infty = 298$ K, 1 atm): $\nu = 15.8 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0262 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.71$; ($T_s = 313$ K, 1 atm): $\text{Pr} = 0.705$.

ANALYSIS: (a) The rate of heat transfer per unit cylinder length is

$$q' = (q/L) = \bar{h}(\pi D) (T_s - T_\infty)$$

where, from the Zhukauskas relation, with $\text{Pr} \approx \text{Pr}_s$,

$$\bar{h} = \frac{k}{D} C \text{Re}_D^m \text{Pr}^n = \frac{k}{D} C \left(\frac{VD}{\nu} \right)^m \text{Pr}^n$$

Hence,

$$V = \left[\frac{q'}{(k/D) C \text{Pr}^n (\pi D) (T_s - T_\infty)} \right]^{1/m} \left(\frac{\nu}{D} \right). \quad <$$

(b) Assuming $(10^3 < \text{Re}_D < 2 \times 10^5)$, $C = 0.26$, $m = 0.6$ from Table 7.3. Hence,

$$V = \left[\frac{35 \text{ W/m}}{0.0262 \text{ W/m}\cdot\text{K} \times 0.26 (0.71)^{0.37} \pi (40 - 25)^\circ \text{C}} \right]^{1/0.6} \left(\frac{15.8 \times 10^{-6} \text{ m}^2/\text{s}}{5 \times 10^{-4} \text{ m}} \right)$$

$$V = 97 \text{ m/s}. \quad <$$

To verify the assumption of the Reynolds number range, calculate

$$\text{Re}_D = \frac{VD}{\nu} = \frac{97 \text{ m/s} (5 \times 10^{-4} \text{ m})}{15.8 \times 10^{-6} \text{ m}^2/\text{s}} = 3074.$$

Hence the assumption was correct.

COMMENTS: The major uncertainty associated with using this method to determine V is that associated with use of the correlation for $\bar{\text{Nu}}_D$.

PROBLEM 7.50

KNOWN: Platinum wire maintained at a constant temperature in an airstream to be used for determining air velocity changes.

FIND: (a) Relationship between fractional changes in current to maintain constant wire temperature and fractional changes in air velocity and (b) Current required when air velocity is 10 m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Cross-flow of air on wire with $40 < \text{Re}_D < 1000$, (3) Radiation effects negligible, (4) Wire is isothermal.

PROPERTIES: Platinum wire (given): Electrical resistivity, $\rho_e = 17.1 \times 10^{-5} \text{ Ohm}\cdot\text{m}$; *Table A-4*, Air ($T_\infty = 27^\circ\text{C} = 300 \text{ K}$, 1 atm): $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0263 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.707$; ($T_s = 77^\circ\text{C} = 350 \text{ K}$, 1 atm): $\text{Pr}_s = 0.700$.

ANALYSIS: (a) From an energy balance on a unit length of the platinum wire,

$$q'_{\text{elec}} - q'_{\text{conv}} = I^2 R'_e - \bar{h}P(T_s - T_\infty) = 0 \quad (1)$$

where the electrical resistance per unit length is $R'_e = \rho_e / A_c$, $P = \pi D$, and $A_c = \pi D^2 / 4$. Hence,

$$I = \left[\frac{\bar{h} P A_c}{\rho_e} (T_s - T_\infty) \right]^{1/2} = \left[\frac{\pi^2 \bar{h} D^3}{4 \rho_e} (T_s - T_\infty) \right]^{1/2} \quad (2)$$

For the range $40 < \text{Re}_D < 1000$, using the Zhukauskas correlation for cross-flow over a cylinder with $C = 0.51$ and $m = 0.5$,

$$\overline{\text{Nu}}_D = \frac{\bar{h} D}{k} = 0.51 \text{Re}_D^{0.5} \text{Pr}^{0.37} \left(\frac{\text{Pr}}{\text{Pr}_s} \right)^{1/4} = 0.51 \left(\frac{VD}{\nu} \right)^{0.5} \text{Pr}^{0.37} \left(\frac{\text{Pr}}{\text{Pr}_s} \right)^{1/4} \quad (3)$$

note that $\bar{h} \sim V^{0.5}$, which, when substituted into Eq. (2) yields

$$I \sim \bar{h}^{1/2} = (V^{0.5})^{1/2} = V^{1/4}$$

Differentiating the proportionality and dividing the result by the proportionality, it follows that

$$\frac{\Delta I}{I} \approx \frac{1}{4} \frac{\Delta V}{V} \quad (4) <$$

(b) For air at $T_\infty = 27^\circ\text{C}$ and $V = 10 \text{ m/s}$, the current required to maintain the wire of $D = 0.5 \text{ mm}$ at $T_s = 77^\circ\text{C}$ follows from Eq. (2) with \bar{h} evaluated by Eq. (3)

Continued

PROBLEM 7.50 (Cont.)

$$\begin{aligned}\bar{h} &= \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.0005 \text{ m}} \times 0.51 \left(\frac{10 \text{ m/s} \times 0.0005 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{0.5} (0.707)^{0.37} \left(\frac{0.707}{0.700} \right)^{1/4} \\ \bar{h} &= 420 \text{ W/m}^2 \cdot \text{K}\end{aligned}$$

where $Re_D = 315$. Hence the required current is

$$I = \left[\frac{\pi^2 \times 420 \text{ W/m}^2 \cdot \text{K} (0.0005 \text{ m})^3}{4 \times 17.1 \times 10^{-5} \Omega \cdot \text{m}} (77 - 27) \text{ K} \right]^{1/2} = 195 \text{ mA.} \quad (5)$$

COMMENTS: (1) To measure 1% fractional velocity change, a 0.25% fractional change in current must be measured according to Eq. (4). From Eq. (5), this implies that $\Delta I = 0.0025I = 0.0025 \times 195 \text{ mA} = 488 \mu\text{A}$. An electronic circuit with such measurement sensitivity requires care in its design.

(2) Instruments built on this principle to measure air velocities are called *hot-wire anemometers*. Generally, the wire diameters are much smaller (3 to 30 μm vs 500 μm of this problem) in order to have faster response times.

(3) What effect would the presence of radiation exchange between the wire and its surroundings have?

PROBLEM 7.51

KNOWN: Temperature sensor of 12.5 mm diameter experiences cross-flow of water at 80°C and velocity, $0.005 < V < 0.20$ m/s. Sensor temperature may vary over the range $20 < T_s < 80^\circ\text{C}$.

FIND: Expression for convection heat transfer coefficient as a function of T_s and V .

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Sensor-water flow approximates a cylinder in cross-flow, (3) Prandtl number varies linearly with temperature over the range of interest.

PROPERTIES: Table A-6, Sat. water ($T_\infty = 80^\circ\text{C} = 353$ K): $k = 0.670$ W/m·K, $\nu = \mu/\rho = 352 \times 10^{-6}$ m²/s, $\text{Pr} = \nu/\alpha = 7.00$ at $T_s = 293$ K, $\text{Pr} = 2.20$ at $T_s = 353$ K. Pr_s values for $20 \leq T_s \leq 80^\circ\text{C}$:

T (K)	293	300	325	350	353
Pr	7.00	5.83	3.42	2.29	2.20

ANALYSIS: Using the Zhukauskus correlation for the range $40 < \text{Re}_D < 4000$ with $C = 0.51$ and $m = 0.5$,

$$\overline{\text{Nu}}_D = \frac{\bar{h}D}{k} = 0.51 \text{Re}_D^{0.5} \text{Pr}^{0.37} \left(\frac{\text{Pr}}{\text{Pr}_s} \right)^{1/4}$$

with $\text{Re}_D = VD/\nu$, the thermophysical properties of interest are k , ν and Pr , which are evaluated at $T_\infty = 80^\circ\text{C}$, and Pr_s which varies markedly with T_s for the range $20 < T_s < 80^\circ\text{C}$. Assuming Pr_s to vary linearly with T_s and using the extreme values to find the relation,

$$\text{Pr}_s = 7.00 + \frac{(2.20 - 7.00)}{(353 - 293)\text{K}} (T_s - 293)\text{K} = 7.00 - 0.0800(T_s - 293)$$

where the units of T_s are [K]. Substituting numerical values, find

$$\bar{h}(T_s) = \frac{0.670 \text{ W/m}\cdot\text{K}}{0.0125 \text{ m}} 0.51 \left(\frac{V \times 0.0125 \text{ m}}{3.621 \times 10^{-7} \text{ m}^2/\text{s}} \right)^{0.5} (2.20)^{0.37} \left(\frac{2.20}{7.00 - 0.080(T_s - 293)} \right)^{1/4}$$

$$\bar{h}(T_s) = 6800V^{0.5} [3.182 - 0.0364(T_s - 293)]^{-1/4} \quad <$$

COMMENTS: (1) From the Pr_s vs T_s graph above, a linear fit is seen to be poor for this temperature range. However, because the Pr_s dependence is to the $1/4$ power, the discrepancy may be acceptable.

PROBLEM 7.52

KNOWN: Diameter, electrical resistance and current for a high tension line. Velocity and temperature of ambient air.

FIND: (a) Surface and (b) Centerline temperatures of the wire, (c) Effect of air velocity on surface temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional radial conduction.

PROPERTIES: Table A.4, Air ($T_f \approx 300$ K, 1 atm): $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0263 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.707$; Table A.1, Copper ($T \approx 300$ K): $k = 400 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) Applying conservation of energy to a control volume of unit length,

$$\dot{E}'_g = I^2 R'_e = q' = \bar{h} \pi D (T_s - T_\infty)$$

With

$$\text{Re}_D = \frac{VD}{\nu} = \frac{10 \text{ m/s}(0.025 \text{ m})}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 15,733$$

the Churchill and Bernstein correlation, yields

$$\overline{\text{Nu}}_D = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5} = 69.0$$

Hence,

$$\bar{h} = \overline{\text{Nu}}_D \frac{k}{D} = 69.0 \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} = 72.6 \text{ W/m}^2\cdot\text{K}$$

and

$$T_s = T_\infty + \frac{I^2 R'_e}{\bar{h} \pi D} = 10^\circ\text{C} + \frac{(1000 \text{ A})^2 10^{-4} \Omega/\text{m}}{(72.6 \text{ W/m}^2\cdot\text{K}) \pi (0.025 \text{ m})} = 10^\circ\text{C} + 17.6^\circ\text{C} = 27.6^\circ\text{C} \quad <$$

(b) With $\dot{q} = \dot{E}'_g / (\pi D^2/4) = 4(1000 \text{ A})^2 (10^{-4} \Omega/\text{m}) / \pi (0.025 \text{ m})^2 = 2.04 \times 10^5 \text{ W/m}^3$, Equation 3.53 yields

$$T(0) = \frac{\dot{q} r_o^2}{4k} + T_s = \frac{2.041 \times 10^5 \text{ W/m}^3 (0.0125 \text{ m})^2}{1600 \text{ W/m}\cdot\text{K}} + 27.6^\circ\text{C} = 0.02^\circ\text{C} + 27.6^\circ\text{C} \approx 27.6^\circ\text{C} \quad <$$

Continued...

PROBLEM 7.52 (Cont.)

(c) The effect of V on the surface temperature was determined using the *Correlations and Properties* Tool Pads of IHT.

The effect is significant, with a surface temperature of $T_s \approx 70^\circ\text{C}$ corresponding to $V = 1$ m/s. For velocities of 1 and 10 m/s, respectively, convection coefficients are 21.1 and 72.8 $\text{W/m}^2\cdot\text{K}$ and film temperatures are 313.2 and 291.7 K.

COMMENTS: The small values of \dot{q} and r_o and the large value of k render the wire approximately isothermal.

PROBLEM 7.53

KNOWN: Aluminum transmission line with a diameter of 20 mm having an electrical resistance of $R' = 2.636 \times 10^{-4} \text{ ohm/m}$ carrying a current of 700 A subjected to severe cross winds. To reduce potential fire hazard when adjacent lines make contact and spark, insulation is to be applied.

FIND: (a) The bare conductor temperature when the air temperature is 20°C and the line is subjected to cross flow with a velocity of 10 m/s; (b) The conductor temperature for the same conditions, but with an insulation covering of 2 mm thickness and thermal conductivity of $0.15 \text{ W/m}\cdot\text{K}$; and (c) Plot the conductor temperatures of the bare and insulated conductors for wind velocities in the range of 2 to 20 m/s. Comment on the features of the curves and the effect that wind velocity has on the conductor operating temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperatures, (3) Negligible solar irradiation and radiation exchange, and (4) Constant properties.

PROPERTIES: Table A-4, Air ($T_f = (T_s + T_\infty)/2$, 1 atm): evaluated using the *IHT Properties* library with a *Correlation* function; see Comment 2.

ANALYSIS: (a) For the bare conductor the energy balance per unit length is

$$\begin{aligned} \dot{E}'_{\text{in}} - \dot{E}'_{\text{out}} + \dot{E}'_{\text{gen}} &= 0 \\ 0 - q'_{\text{cv}} + \dot{q} A_c &= 0 \end{aligned} \quad (1)$$

where the cross-sectional area of the conductor is $A_c = \pi D^2/4$ and the generation rate is

$$\begin{aligned} \dot{q} &= I^2 R'_e / A_c = (700 \text{ A})^2 \times 2.636 \times 10^{-4} \text{ } \Omega/\text{m} / \left(\pi (0.020 \text{ m})^2 / 4 \right) \\ \dot{q} &= 4.111 \times 10^5 \text{ W/m}^3 \end{aligned} \quad (2)$$

The convection rate equation can be expressed as

$$q'_{\text{cv}} = (T_{c,\text{bare}} - T_\infty) / R'_t \quad R'_t = 1 / (\bar{h}_D \times \pi D) \quad (3,4)$$

and the convection coefficient is estimated using the Churchill-Bernstein correlation, Eq. 7.54, with $Re_D = VD/\nu$,

$$\overline{Nu}_L = \frac{\bar{h}_D D}{k} = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3} \right]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000} \right)^{5/8} \right]^{4/5} \quad (4)$$

(b) For the conductor with insulation thickness $t = 2 \text{ mm}$, the energy balance per unit length is

$$\begin{aligned} \dot{E}'_{\text{in}} - \dot{E}'_{\text{out}} + \dot{E}'_{\text{gen}} &= 0 \\ 0 - (T_{c,\text{ins}} - T_\infty) / R'_t + I^2 R'_e / A_c &= 0 \end{aligned} \quad (5)$$

Continued

PROBLEM 7.53 (Cont.)

where R'_t is the sum of the insulation conduction and convection process thermal resistances,

$$R'_t = \ln[(D+2t)/D]/(2\pi k) + 1/[\bar{h}_{D+2t}\pi(D+2t)] \quad (6)$$

The results of the analysis using *IHT* are tabulated below.

Condition	V (m/s)	D (mm)	Re_D	\overline{Nu}_D	\bar{h}_D (W/m ² ·K)	R'_t (m·K/W)	T_c (°C)
bare	10	20	1.214×10^4	59.6	79.6	0.1998	45.8
insulated	10	24	1.468×10^4	66.3	73.6	0.3736	68.3

(c) Using the *IHT* code with the foregoing relations, the conductor temperatures $T_{c,bare}$ and $T_{c,ins}$ for the bare and insulated conditions are calculated and plotted for the wind velocity range of 2 to 20 m/s.

COMMENTS: (1) The effect of the 2-mm thickness insulation is to increase the conductor operating temperature by $(68.3 - 46.1)^\circ\text{C} = 22^\circ\text{C}$. While we didn't account for an increase in the electrical resistivity with increasing temperature, the adverse effect is to increase the I^2R loss, which represents a loss of revenue to the power provider. From the graph, note that the conductor temperature increases markedly with decreasing wind velocity, and the effect of insulation is still around $+20^\circ\text{C}$.

(2) Because of the tediousness of hand calculations required in using the convection correlation without fore-knowledge of T_f at which to evaluate properties, we used the *IHT Correlation* function treating T_f as one of the unknowns in the system of equations. Salient portions of the *IHT* code and property values are provided below.

Pr = Pr_T("Air",Tf)                      // Prandtl number
```

(3) Is the temperature gradient within the conductor significant?

PROBLEM 7.54

KNOWN: Velocities and temperatures of two air streams separated by a wall. Dimensions of an aluminum pin fin inserted through the wall. Distance it extends into the upper fluid.

FIND: (a) Heat transfer rate between the fluids via the pin fin, when it extends 50 mm into the upper fluid. (b) Heat transfer rate as a function of the distance it extends into the upper fluid.

SCHEMATIC:

ASSUMPTIONS: (1) Velocity is uniform – decreased velocity near wall can be neglected, (2) For the purpose of evaluating properties, the fin temperature is equal to the average of the two fluid temperatures, $T_s = 25^\circ\text{C}$.

PROPERTIES: Table A-4, Air 1 ($T_f = 17.5^\circ\text{C} \approx 290.5\text{ K}$): $\nu_1 = 1.504 \times 10^{-5}\text{ m}^2/\text{s}$, $k_1 = 0.02554\text{ W/m}\cdot\text{K}$, $\text{Pr}_1 = 0.710$. Air 2 ($T_f = 32.5^\circ\text{C} \approx 305.5\text{ K}$): $\nu_2 = 1.644 \times 10^{-5}\text{ m}^2/\text{s}$, $k_2 = 0.02671\text{ W/m}\cdot\text{K}$, $\text{Pr}_2 = 0.706$. Table A-1, Aluminum 2024 ($T_s = 25^\circ\text{C} \approx 300\text{ K}$): $k = 177\text{ W/m}\cdot\text{K}$.

ANALYSIS:

(a) The heat transfer coefficients between the air and the fin are analyzed as flow past a cylinder using the Churchill-Bernstein correlation:

$$\text{Re}_{D1} = \frac{V_1 D}{\nu_1} = \frac{10\text{ m/s} \times 0.005\text{ m}}{1.504 \times 10^{-5}\text{ m}^2/\text{s}} = 3320$$

$$\text{Re}_{D2} = \frac{V_2 D}{\nu_2} = \frac{3\text{ m/s} \times 0.005\text{ m}}{1.644 \times 10^{-5}\text{ m}^2/\text{s}} = 912.$$

From Equation 7.54,

$$\begin{aligned} \text{Nu}_{D1} &= 0.3 + \frac{0.62 \text{Re}_{D1}^{1/2} \text{Pr}_1^{1/3}}{\left[1 + (0.4/\text{Pr}_1)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_{D1}}{282,000}\right)^{5/8}\right]^{4/5} \\ &= 0.3 + \frac{0.62 \times (3320)^{1/2} \times (0.710)^{1/3}}{\left[1 + (0.4/0.710)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{3320}{282,000}\right)^{5/8}\right]^{4/5} = 29.7 \end{aligned}$$

$$\text{and } h_1 = \frac{\text{Nu}_{D1} k_1}{D} = \frac{29.7 \times 0.02554\text{ W/m}\cdot\text{K}}{0.005\text{ m}} = 152\text{ W/m}^2\cdot\text{K}$$

Continued....

PROBLEM 7.54 (Cont.)

Similarly, $Nu_{D2} = 15.3$, $h_2 = 81.5 \text{ W/m}^2 \cdot \text{K}$.

Next we analyze heat transfer along the rod as if it were two fins joined at their base – the location where the fin passes through the wall. Thus, using the corrected fin length approach, Equation 3.88,

$$\begin{aligned} q_1 &= M_1 \tanh m_1 L_{c1} \\ q_2 &= M_2 \tanh m_2 L_{c2} \end{aligned}$$

where

$$\begin{aligned} M_1 &= \sqrt{h_1 P k A_c} \theta_{bi} = \sqrt{h_1 D k} \frac{\pi D}{2} (T_b - T_{\infty 1}) \\ m_1 &= \sqrt{h_1 P / k A_c} = 2\sqrt{h_1 / k D} \end{aligned}$$

and $L_{ci} = L_i + D/4$. In this expression, $L_1 = d$ and $L_2 = L - d$. Finally, since heat leaving one rod enters the other,

$$\begin{aligned} q_1 &= -q_2 \\ \sqrt{h_1 D k} \frac{\pi D}{2} (T_b - T_{\infty 1}) \tanh m_1 L_{c1} &= -\sqrt{h_2 D k} \frac{\pi D}{2} (T_b - T_{\infty 2}) \tanh m_2 L_{c2} \end{aligned}$$

Solving for T_b :

$$T_b = \frac{\sqrt{h_1} T_{\infty 1} \tanh(m_1 L_{c1}) + \sqrt{h_2} T_{\infty 2} \tanh(m_2 L_{c2})}{\sqrt{h_1} \tanh(m_1 L_{c1}) + \sqrt{h_2} \tanh(m_2 L_{c2})} \quad (1)$$

We calculate

$$m_1 = 2\sqrt{h_1 / k D} = 2\sqrt{152 \text{ W/m}^2 \cdot \text{K} / (177 \text{ W/m} \cdot \text{K} \times 0.005 \text{ m})} = 26.2 \text{ m}^{-1}$$

and similarly $m_2 = 19.2 \text{ m}^{-1}$. Also, $L_{c1} = L_{c2} = d + D/4 = 0.05 \text{ m} + 0.005 \text{ m}/4 = 0.05125 \text{ m}$.

Thus

$$\begin{aligned} T_b &= \frac{\left[\sqrt{152 \text{ W/m}^2 \cdot \text{K}} \times 10^\circ\text{C} \times \tanh(26.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \right. \\ &\quad \left. + \sqrt{81.5 \text{ W/m}^2 \cdot \text{K}} \times 40^\circ\text{C} \times \tanh(19.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \right]}{\left[\sqrt{152 \text{ W/m}^2 \cdot \text{K}} \times \tanh(26.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \right. \\ &\quad \left. + \sqrt{81.5 \text{ W/m}^2 \cdot \text{K}} \times \tanh(19.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \right]} = 21.6^\circ\text{C} \end{aligned}$$

Finally

$$\begin{aligned} q &= q_1 = -q_2 = \sqrt{h_1 D k} \frac{\pi D}{2} (T_b - T_{\infty 1}) \tanh(m_1 L_{c1}) \\ &= \sqrt{152 \text{ W/m}^2 \cdot \text{K} \times 0.005 \text{ m} \times 177 \text{ W/m} \cdot \text{K}} \times \frac{\pi(0.005 \text{ m})}{2} \\ &\quad \times (21.6^\circ\text{C} - 10^\circ\text{C}) \tanh(26.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \\ &= 0.924 \text{ W} \end{aligned} \quad (2)$$

<

PROBLEM 7.54 (Cont.)

(b) With $L_{c1} = d + D/4$ and $L_{c2} = L - d + D/4$, we vary d in the range $0 \leq d \leq 0.1$ m and solve Equations (1) and (2). The results for q are plotted below.

We see that there is an optimal insertion distance, $d \approx 40$ mm. A longer fin length (≈ 60 mm) is needed in fluid 2 to compensate for its smaller heat transfer coefficient.

COMMENTS: It is of interest to compare the heat transfer between the two fluids via the fin to the heat transfer through the wall. In Chapter 8 we will see how to calculate heat transfer coefficients for flow in a channel. Assuming that the channel widths are both approximately 50 mm, the heat transfer coefficients between the fluid and the wall are roughly $40 \text{ W/m}^2\cdot\text{K}$ and $10 \text{ W/m}^2\cdot\text{K}$ for the faster and

slower streams, respectively. Then $q'' = \frac{T_2 - T_1}{1/h_1 + 1/h_2} \approx 240 \text{ W/m}^2$. A wall area of $4 \times 10^{-3} \text{ m}^2$, for example a 60 mm-square area, would be required to transfer the same amount of heat as the fin (in part a), 0.924 W.

PROBLEM 7.55

KNOWN: Velocities and temperatures of two air streams separated by a wall. Dimensions of an aluminum pin fin inserted through the wall. Distance it extends into the upper fluid.

FIND: (a) Heat transfer rate between the fluids via the pin fin, when it extends 50 mm into the upper fluid. (b) Heat transfer rate as a function of the distance it extends into the upper fluid.

SCHEMATIC:

ASSUMPTIONS: (1) Velocity is uniform – decreased velocity near wall can be neglected, (2) For the purpose of evaluating properties, the fin temperature is equal to the average of the two fluid temperatures, $T_s = 25^\circ\text{C}$.

PROPERTIES: Table A-4, Ethylene glycol ($T_f = 17.5^\circ\text{C} \approx 290.5\text{ K}$): $\nu_1 = 2.17 \times 10^{-5}\text{ m}^2/\text{s}$, $k_1 = 0.2482\text{ W/m}\cdot\text{K}$, $\text{Pr}_1 = 231$. Air ($T_f = 32.5^\circ\text{C} \approx 305.5\text{ K}$): $\nu_2 = 1.644 \times 10^{-5}\text{ m}^2/\text{s}$, $k_2 = 0.02671\text{ W/m}\cdot\text{K}$, $\text{Pr}_2 = 0.706$. Table A-1, Aluminum 2024 ($T_s = 25^\circ\text{C} \approx 300\text{ K}$): $k = 177\text{ W/m}\cdot\text{K}$.

ANALYSIS:

(a) The heat transfer coefficients between the air and the fin are analyzed as flow past a cylinder using the Churchill-Bernstein correlation:

$$\text{Re}_{D1} = \frac{V_1 D}{\nu_1} = \frac{10\text{ m/s} \times 0.005\text{ m}}{2.17 \times 10^{-5}\text{ m}^2/\text{s}} = 2304$$

$$\text{Re}_{D2} = \frac{V_2 D}{\nu_2} = \frac{3\text{ m/s} \times 0.005\text{ m}}{1.644 \times 10^{-5}\text{ m}^2/\text{s}} = 912.$$

From Equation 7.54,

$$\begin{aligned} \text{Nu}_{D1} &= 0.3 + \frac{0.62 \text{Re}_{D1}^{1/2} \text{Pr}_1^{1/3}}{\left[1 + (0.4/\text{Pr}_1)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_{D1}}{282,000}\right)^{5/8}\right]^{4/5} \\ &= 0.3 + \frac{0.62 \times (2304)^{1/2} \times (231)^{1/3}}{\left[1 + (0.4/231)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{2304}{282,000}\right)^{5/8}\right]^{4/5} = 189 \end{aligned}$$

$$\text{and } h_1 = \frac{\text{Nu}_{D1} k_1}{D} = \frac{189 \times 0.2482\text{ W/m}\cdot\text{K}}{0.005\text{ m}} = 9400\text{ W/m}^2\cdot\text{K}$$

Continued....

PROBLEM 7.55 (Cont.)

Similarly, $Nu_{D2} = 15.3$, $h_2 = 81.5 \text{ W/m}^2 \cdot \text{K}$.

Next we analyze heat transfer along the rod as if it were two fins joined at their base – the location where the fin passes through the wall. Thus, using the corrected fin length approach, Equation 3.88,

$$\begin{aligned} q_1 &= M_1 \tanh m_1 L_{c1} \\ q_2 &= M_2 \tanh m_2 L_{c2} \end{aligned}$$

where

$$\begin{aligned} M_i &= \sqrt{h_i P k A_c} \theta_{bi} = \sqrt{h_i D k} \frac{\pi D}{2} (T_b - T_{\infty i}) \\ m_i &= \sqrt{h_i P / k A_c} = 2\sqrt{h_i / k D} \end{aligned}$$

and $L_{ci} = L_i + D/4$. In this expression, $L_1 = d$ and $L_2 = L - d$. Finally, since heat leaving one rod enters the other,

$$\begin{aligned} q_1 &= -q_2 \\ \sqrt{h_1 D k} \frac{\pi D}{2} (T_b - T_{\infty 1}) \tanh m_1 L_{c1} &= -\sqrt{h_2 D k} \frac{\pi D}{2} (T_b - T_{\infty 2}) \tanh m_2 L_{c2} \end{aligned}$$

Solving for T_b :

$$T_b = \frac{\sqrt{h_1} T_{\infty 1} \tanh(m_1 L_{c1}) + \sqrt{h_2} T_{\infty 2} \tanh(m_2 L_{c2})}{\sqrt{h_1} \tanh(m_1 L_{c1}) + \sqrt{h_2} \tanh(m_2 L_{c2})} \quad (1)$$

We calculate

$$m_1 = 2\sqrt{h_1 / k D} = 2\sqrt{9400 \text{ W/m}^2 \cdot \text{K} / (177 \text{ W/m} \cdot \text{K} \times 0.005 \text{ m})} = 103 \text{ m}^{-1}$$

and similarly $m_2 = 19.2 \text{ m}^{-1}$. Also, $L_{c1} = L_{c2} = d + D/4 = 0.05 \text{ m} + 0.005 \text{ m}/4 = 0.05125 \text{ m}$.

Thus

$$T_b = \frac{\left[\sqrt{9400 \text{ W/m}^2 \cdot \text{K}} \times 10^\circ\text{C} \times \tanh(103 \text{ m}^{-1} \times 0.05125 \text{ m}) + \sqrt{81.5 \text{ W/m}^2 \cdot \text{K}} \times 40^\circ\text{C} \times \tanh(19.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \right]}{\left[\sqrt{9350 \text{ W/m}^2 \cdot \text{K}} \times \tanh(103 \text{ m}^{-1} \times 0.05125 \text{ m}) + \sqrt{81.5 \text{ W/m}^2 \cdot \text{K}} \times \tanh(19.2 \text{ m}^{-1} \times 0.05125 \text{ m}) \right]} = 12.0^\circ\text{C}$$

Finally

$$\begin{aligned} q = q_1 = -q_2 &= \sqrt{h_1 D k} \frac{\pi D}{2} (T_b - T_{\infty 1}) \tanh(m_1 L_{c1}) \\ &= \sqrt{9400 \text{ W/m}^2 \cdot \text{K}} \times 0.005 \text{ m} \times 177 \text{ W/m} \cdot \text{K} \times \frac{\pi(0.005 \text{ m})}{2} \\ &\quad \times (12.0^\circ\text{C} - 10^\circ\text{C}) \tanh(103 \text{ m}^{-1} \times 0.05125 \text{ m}) \\ &= 1.41 \text{ W} \end{aligned} \quad (2)$$

<

PROBLEM 7.55 (Cont.)

(b) With $L_{c1} = d + D/4$ and $L_{c2} = L - d + D/4$, we vary d in the range $0 \leq d \leq 0.1$ m and solve Equations (1) and (2). The results for q are plotted below.

We see that there is an optimum for small d , that is, the fin extends mostly into the air. A longer fin length is needed in air to compensate for its smaller heat transfer coefficient.

COMMENTS: It is of interest to compare the heat transfer between the two fluids via the fin to the heat transfer through the wall. In Chapter 8 we will see how to calculate heat transfer coefficients for flow in a channel. Assuming that the channel widths are both approximately 50 mm, the heat transfer coefficients between the fluid and the wall are roughly $2000 \text{ W/m}^2\cdot\text{K}$ and $10 \text{ W/m}^2\cdot\text{K}$ for the ethylene glycol and air streams, respectively. Then $q'' = \frac{T_2 - T_1}{1/h_1 + 1/h_2} \approx 500 \text{ W/m}^2$. A wall area of $3 \times 10^{-3} \text{ m}^2$,

for example a roughly 50 mm-square area, would be required to transfer the same amount of heat as the fin (in part a), 1.41 W.

PROBLEM 7.56

KNOWN: Diameter, thickness and thermal conductivity of steel pipe. Temperature of water flow in pipe. Temperature and velocity of air in cross flow over pipe. Cost of producing hot water.

FIND: (a) Cost of daily heat loss from an uninsulated pipe, (b) Savings associated with insulating the pipe.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible convection resistance for water flow, (3) Negligible contact resistance between insulation and pipe, (4) Negligible radiation.

PROPERTIES: Table A-4, air ($p = 1 \text{ atm}$, $T_f \approx 300 \text{ K}$): $k_a = 0.0263 \text{ W/m} \cdot \text{K}$.

$$\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, \text{ Pr} = 0.707.$$

ANALYSIS: (a) With $\text{Re}_D = VD_o/\nu = 3 \text{ m/s} \times 0.1 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 18,880$, application of the Churchill-Bernstein correlation yields

$$\overline{\text{Nu}}_D = 0.3 + \frac{0.62(18,880)^{1/2}(0.707)^{1/3}}{\left[1 + (0.4/0.707)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{18,880}{282,000}\right)^{5/8}\right]^{4/5} = 76.6$$

$$\bar{h} = \frac{k_a}{D_o} \overline{\text{Nu}}_D = \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.1 \text{ m}} 76.6 = 20.1 \text{ W/m}^2 \cdot \text{K}$$

Without the insulation, the total thermal resistance and heat loss per length of pipe are then

$$\begin{aligned} R'_{\text{tot(wo)}} &= \frac{\ln(D_o/D_i)}{2\pi k_p} + \frac{1}{\pi D_o \bar{h}} = \frac{\ln(100/84)}{2\pi \times 60 \text{ W/m} \cdot \text{K}} + \frac{1}{\pi (0.1 \text{ m}) 20.1 \text{ W/m}^2 \cdot \text{K}} \\ &= (4.63 \times 10^{-4} + 0.158) \text{ m} \cdot \text{K/W} = 0.159 \text{ m} \cdot \text{K/W} \end{aligned}$$

$$q'_{\text{wo}} = \frac{T - T_\infty}{R'_{\text{tot(wo)}}} = \frac{55^\circ\text{C}}{0.159 \text{ m} \cdot \text{K/W}} = 346 \text{ W/m} = 0.346 \text{ kW/m}$$

The corresponding daily energy loss is

$$Q'_{\text{wo}} = 0.346 \text{ kW/m} \times 24 \text{ h/d} = 8.3 \text{ kW} \cdot \text{h/m} \cdot \text{d}$$

and the associated cost is

$$C'_{\text{wo}} = (8.3 \text{ kW} \cdot \text{h/m} \cdot \text{d})(\$0.05/\text{kW} \cdot \text{h}) = \$0.415/\text{m} \cdot \text{d}$$

<

(b) The conduction resistance of the insulation is

Continued

PROBLEM 7.56 (Cont.)

$$R'_{\text{cnd}} = \frac{\ln(D_o/D_i)}{2\pi k_i} = \frac{\ln(120/100)}{2\pi(0.026 \text{ W/m}\cdot\text{K})} = 1.116 \text{ m}\cdot\text{K/W}$$

Using the Churchill-Bernstein correlation with an outside diameter of $D_o = 0.12\text{m}$, $Re_D = 22,660$, $\overline{Nu}_D = 83.9$ and $\overline{h} = 18.4 \text{ W/m}^2\cdot\text{K}$. The convection resistance is then

$$R'_{\text{cnv}} = \frac{1}{\pi D_o \overline{h}} = \frac{1}{\pi(0.12\text{m})18.4 \text{ W/m}^2\cdot\text{K}} = 0.144 \text{ m}\cdot\text{K/W}$$

and the total resistance is

$$R'_{\text{tot(w)}} = (4.63 \times 10^{-4} + 1.116 + 0.144) \text{ m}\cdot\text{K/W} = 1.261 \text{ m}\cdot\text{K/W}$$

The heat loss and cost are then

$$q'_w = \frac{T - T_\infty}{R'_{\text{tot(w)}}} = \frac{55^\circ\text{C}}{1.261 \text{ m}\cdot\text{K/W}} = 43.6 \text{ W/m} = 0.0436 \text{ kW/m}$$

$$C'_w = 0.0436 \text{ kW/m} \times 24 \text{ h/d} \times \$0.05/\text{kW}\cdot\text{h} = \$0.052/\text{m}\cdot\text{d}$$

The daily savings is then

$$S' = C'_{w0} - C'_w = \$0.363/\text{m}\cdot\text{d} \quad <$$

COMMENTS: (1) The savings are significant, and the pipe should be insulated. (2) Assuming a negligible temperature drop across the pipe wall, a pipe emissivity of $\epsilon_p = 0.6$ and surroundings at $T_{\text{sur}} = 268\text{K}$, the radiation coefficient associated with the uninsulated pipe is $h_r = \epsilon\sigma(T + T_{\text{sur}})(T^2 + T_{\text{sur}}^2) = 0.6 \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 (591\text{K}) (323^2 + 268^2) \text{ K}^2 = 3.5 \text{ W/m}^2\cdot\text{K}$. Accordingly, radiation increases the heat loss estimate of Part (a) by approximately 17%.

PROBLEM 7.57

KNOWN: Diameter and surface temperature of an uninsulated steam pipe. Velocity and temperature of air in cross flow.

FIND: (a) Heat loss per unit length, (b) Effect of insulation thickness on heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation.

PROPERTIES: Table A.4, Air ($T_f \approx 350$ K, 1 atm): $\nu = 20.9 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.030 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.70$.

ANALYSIS: (a) Without the insulation, the heat loss per unit length is

$$q' = \bar{h} \pi D (T_{s,i} - T_{\infty})$$

where \bar{h} may be obtained from the Churchill-Bernstein relation. With

$$\text{Re}_D = \frac{VD}{\nu} = \frac{5 \text{ m/s} \times 0.5 \text{ m}}{20.9 \times 10^{-6} \text{ m}^2/\text{s}} = 1.196 \times 10^5$$

$$\overline{\text{Nu}}_D = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5} = 242$$

$$\bar{h} = \overline{\text{Nu}}_D \frac{k}{D} = 242 \frac{0.030 \text{ W/m}\cdot\text{K}}{0.5 \text{ m}} = 14.5 \text{ W/m}^2 \cdot \text{K}$$

The heat rate is then

$$q' = 14.5 \text{ W/m}^2 \cdot \text{K} \pi (0.5 \text{ m}) (150 - (-10))^\circ \text{C} = 3644 \text{ W/m}.$$

(b) With the insulation, the heat loss may be expressed as

$$q' = U_i \pi D (T_{s,i} - T_{\infty})$$

where, from Eq. 3.31,

$$U_i = \left[\frac{(D/2)}{k_i} \ln \bar{r} + \frac{1}{\bar{r}h} \right]^{-1}$$

and $\bar{r} \equiv (D/2 + \delta)/(D/2)$. The outer diameter, $D_o = D + 2\delta$, as well as the film temperature, $T_f = (T_{s,o} + T_{\infty})/2$, must now be used to evaluate the convection coefficient, where

Continued...

PROBLEM 7.57 (Cont.)

$$\frac{T_{s,i} - T_{s,o}}{T_{s,i} - T_{\infty}} = \frac{R'_{\text{cond}}}{R'_{\text{tot}}} = \frac{(\ln \bar{r})/k_i}{(\ln \bar{r})/k_i + 1/(D/2) \bar{r} \bar{h}}$$

Using the IHT *Correlations and Properties* Tool Pads to evaluate \bar{h} , the following results were obtained.

The insulation is extremely effective, with a thickness of only 10 mm yielding a 7-fold reduction in heat loss and decreasing the outer surface temperature from 150 to 10°C. For $\delta = 50$ mm, $U_i = 0.56 \text{ W/m}^2 \cdot \text{K}$, $q' = 140 \text{ W/m}$ and $T_{s,o} = -5.2^\circ\text{C}$.

COMMENTS: The dominant contribution to the total thermal resistance is made by the insulation.

PROBLEM 7.58

KNOWN: Dimensions and thermal conductivity of a thermocouple well. Temperatures at well tip and base. Air velocity.

FIND: Air temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional conduction along well, (4) Uniform convection coefficient, (5) Negligible radiation.

PROPERTIES: Steel (given): $k = 35 \text{ W/m}\cdot\text{K}$; Air (given): $\rho = 0.774 \text{ kg/m}^3$, $\mu = 251 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$, $k = 0.0373 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.686$.

ANALYSIS: Applying Equation 3.70 at the well tip ($x = L$), where $T = T_1$,

$$\frac{T_1 - T_\infty}{T_2 - T_\infty} = \left[\cosh mL + (\bar{h}/mk) \sinh mL \right]^{-1}$$

$$m = (\bar{h}P/kA_c)^{1/2} \quad P = \pi D_o = \pi (0.010 \text{ m}) = 0.0314 \text{ m}$$

$$A_c = (\pi/4)(D_o^2 - D_i^2) = (\pi/4)(0.010^2 - 0.005^2) \text{ m}^2 = 5.89 \times 10^{-5} \text{ m}^2.$$

$$\text{With } \text{Re}_D = \frac{\rho V D}{\mu} = \frac{0.774 \text{ kg/m}^3 (3 \text{ m/s}) (0.01 \text{ m})}{251 \times 10^{-7} \text{ N}\cdot\text{s/m}^2} = 925$$

$C = 0.51$, $m = 0.5$, $n = 0.37$ and the Zhukauskas correlation yields

$$\overline{\text{Nu}}_D = 0.51 \text{Re}_D^{0.5} \text{Pr}^{0.37} (\text{Pr}/\text{Pr}_s)^{1/4} \approx 0.51 (925)^{0.5} (0.686)^{0.37} \times 1 = 13.5$$

$$\bar{h} = \overline{\text{Nu}}_D \frac{k}{D_o} = 13.5 \frac{0.0373 \text{ W/m}\cdot\text{K}}{0.01 \text{ m}} = 50.4 \text{ W/m}^2 \cdot \text{K}.$$

Hence

$$m = \left[\frac{(50.4 \text{ W/m}^2 \cdot \text{K}) (0.0314 \text{ m})}{(35 \text{ W/m}\cdot\text{K}) (5.89 \times 10^{-5} \text{ m}^2)} \right]^{1/2} = 27.7 \text{ m}^{-1} \quad mL = (27.7 \text{ m}^{-1}) (0.15 \text{ m}) = 4.15.$$

With

$$(\bar{h}/mk) = (50.4 \text{ W/m}^2 \cdot \text{K}) / (27.7 \text{ m}^{-1}) (35 \text{ W/m}\cdot\text{K}) = 0.0519$$

$$\text{find } \frac{T_1 - T_\infty}{T_2 - T_\infty} = [31.9 + (0.0519) 31.8]^{-1} = 0.0298 \quad T_\infty = 452.2 \text{ K.} \quad <$$

COMMENTS: Heat conduction along the wall to the base at 375 K is balanced by convection from the air.

PROBLEM 7.59

KNOWN: Mercury-in-glass thermometer mounted on duct wall used to measure air temperature.

FIND: (a) Relationship for the immersion error, $\Delta T_i = T(L) - T_\infty$ as a function of air velocity, thermometer diameter and length, (b) Length of insertion if ΔT_i is not to exceed 0.25°C when the air velocity is 10 m/s , (c) For the length of part (b), calculate and plot ΔT_i as a function of air velocity for 2 to 20 m/s , and (d) For a given insertion length, will ΔT_i increase or decrease with thermometer diameter increase; is ΔT_i more sensitive to diameter or velocity changes?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Thermometer approximates a one-dimensional (glass) fin with an *adiabatic* tip, (3) Convection coefficient is uniform over length of thermometer.

PROPERTIES: Table A.3, Glass (300 K): $k_g = 1.4\text{ W/m}\cdot\text{K}$; Table A.4, Air ($T_f = (15 + 77)^\circ\text{C}/2 \approx 320\text{ K}$, 1 atm): $k = 0.0278\text{ W/m}\cdot\text{K}$, $\nu = 17.90 \times 10^{-6}\text{ m}^2/\text{s}$, $\text{Pr} = 0.704$.

ANALYSIS: (a) From the analysis of a one-dimensional fin, see Table 3.4,

$$\frac{T_L - T_\infty}{T_b - T_\infty} = \frac{1}{\cosh(mL)} \quad m^2 = \frac{\bar{h}P}{k_g A_c} = \frac{4\bar{h}}{k_g D} \quad (1)$$

where $P = \pi D$ and $A_c = \pi D^2/4$. Hence, the immersion error is

$$\Delta T_i = T(L) - T_\infty = (T_b - T_\infty) / \cosh(mL). \quad (2)$$

Using the Hilpert correlation for the circular cylinder in cross flow,

$$\bar{h} = \frac{k}{D} C \text{Re}_D^m \text{Pr}^{1/3} = \frac{k}{D} C \left(\frac{VD}{\nu} \right)^m \text{Pr}^{1/3} = \frac{k \text{Pr}^{1/3}}{\nu^m} \cdot C \cdot V^m \cdot D^{m-1} \quad (3)$$

$$\bar{h} = N \cdot V^m \cdot D^{m-1} \quad \text{where} \quad N = \frac{k \text{Pr}^{1/3}}{\nu^m} C \quad (4,5)$$

Substituting into Eq. (2), the immersion error is

$$\Delta T_i(V, D, L) = (T_b - T_\infty) / \cosh \left\{ \left[\left(4/k_g \right) N \cdot V^m \cdot D^{m-2} \right]^{1/2} L \right\} \quad (6) <$$

where k_g is the thermal conductivity of the glass thermometer.

(b) When the air velocity is 10 m/s , find

$$\text{Re}_D = \frac{VD}{\nu} = \frac{10\text{ m/s} \times 0.004\text{ m}}{17.9 \times 10^{-6}\text{ m}^2/\text{s}} = 2235$$

Continued...

PROBLEM 7.59 (Cont.)

with $C = 0.683$ and $m = 0.466$ from Table 7.2 for the range $40 < \text{Re}_D < 4000$. From Eqs. (5) and (6),

$$N = \frac{0.0278 \text{ W/m} \cdot \text{K} (0.704)^{1/3}}{(17.9 \times 10^{-6} \text{ m/s}^2)^{0.466}} \times 0.683 = 2.753$$

$$\Delta T_i = (15 - 77) \text{ K} / \cosh \left\{ \left[\frac{4}{1.4 \text{ W/m} \cdot \text{K}} \times 2.753 (10 \text{ m/s})^{0.466} (0.004 \text{ m})^{0.466-2} \right]^{1/2} L \right\}$$

and when $\Delta T_i = -0.25^\circ\text{C}$, find

$$L = 18.7 \text{ mm}$$

(c) For the air velocity range 2 to 20 m/s, find $447 \leq \text{Re}_D \leq 4470$ for which the previous values of C and m of the Hilpert correlation are appropriate. Hence, the immersion error for an insertion length of $L = 18.7$ mm, part (b), find

$$\Delta T_i = (15 - 77) \text{ K} / \cosh \left\{ \left[\frac{4}{1.4 \text{ W/m} \cdot \text{K}} \times 2.753 \times V^{0.466} (0.004 \text{ m}) - 1.534 \right]^{1/2} 0.0187 \right\}$$

$$\Delta T_i = -62^\circ\text{C} / \cosh(3.629 V^{0.233})$$

where the units of V are [m/s]. Entering the above equation into the IHT Workspace the plot shown below was generated.

$V(\text{m/s})$	$\Delta T_i (^\circ\text{C})$
2	-1.74
5	-0.63
10	-0.25
15	-0.14
20	-0.08

(d) For a given insertion length, the immersion error will *increase* if the diameter of the thermometer were *increased*. This follows from Eq. (6) written as

$$\Delta T_i \sim 1 / \cosh \left(A \cdot D^{(m-2)/2} \right) \quad (7)$$

where A is a constant depending on variables other than D . For a given insertion length and air velocity, from Eq. (6)

$$\Delta T_i \sim 1 / \cosh \left(B \cdot V^{m/2} \right) \quad (8)$$

where B is a constant. From Eq. (7) we see ΔT_i relates to change in *diameter* as $D^{-0.767}$ and to change in *velocity* as $V^{0.233}$. That is, to reduce the immersion error decrease D and increase V (both cause ΔT_i to increase!). Based upon the exponents of each parameter, however, diameter change is the more influential.

PROBLEM 7.60

KNOWN: Hot film sensor on a quartz rod maintained at $T_s = 50^\circ\text{C}$.

FIND: (a) Compute and plot the convection coefficient as a function of velocity for water, $0.5 \leq V_w \leq 5$ m/s, and air, $1 \leq V_a \leq 20$ m/s with $T_\infty = 20^\circ\text{C}$ and (b) Suitability of using the hot film sensor for the two fluids based upon Biot number considerations.

SCHEMATIC:

ASSUMPTIONS: (1) Cross-flow over a smooth cylinder, (2) Steady-state conditions, (3) Uniform surface temperature.

PROPERTIES: Table A.6, Water ($T_f = 308$ K, sat liquid); Table A.4, Air ($T_f = 308$ K, 1 atm).

ANALYSIS: (a) Using the *IHT Tool, Correlations, Cylinder*, along with the *Properties Tool* for *Air* and *Water*, results were obtained for the convection coefficients as a function of velocity.

(b) The Biot number, $hD/2k$, is the ratio of the internal to external thermal resistances. When $Bi \gg 1$, the thin film is thermally coupled well to the fluid. When $Bi \leq 1$, significant power from the heater is dissipated axially by conduction in the rod. The Biot numbers for the fluids as a function of velocity are shown below.

We conclude that the sensor is well suited for use with water, but not so for use with air.

Continued...

PROBLEM 7.60 (Cont.)

COMMENTS: A copy of the IHT workspace developed to generate the above plots is shown below.

```
// Problem 7.60

// Correlation Tool: External Flow, Cylinder
/* Correlation description: External cross flow (EF) over cylinder (CY), average coefficient,  $ReDPr > 0.2$ ,
Churchill-Bernstein correlation, Eq 7.57. See Table 7.9. */
// Air flow (a)
NuDbar_a = NuD_bar_EF_CY(ReDa, Pra) // Eq 7.54
NuDbar_a = hDbar_a * D / ka
ReDa = Va * D / nu_a
// Evaluate properties at the film temperature, Tfa.
Tf = (Tinf + Ts) / 2
Bia = hDbar_a * D / (2 * k) // Biot number
// Properties Tool: Air

D = 0.0015 // Diameter, m
Ts = 30 + 273 // Surface temperature, K
Tinf = 20 + 273 // Fluid temperature, K

/* Solve, Explore and Graph: After solving, separate Explore sweeps for  $1 \leq Va \leq 20$  and
 $0.5 \leq Vw \leq 5$  m/s were performed saving results in different Data Sets. Four separate
plot windows were generated. */
```

PROBLEM 7.61

KNOWN: Diameter, temperature and heat flux of a hot-film sensor. Fluid temperature. Thickness and thermal conductivity of deposit.

FIND: (a) Fluid velocity, (b) Heat flux if sensor is coated by a deposit.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) Thickness of hot film sensor is negligible, (4) Applicability of Churchill-Bernstein correlation for uniform surface heat flux, (5) $Re_D \ll 282,000$, (6) Deposit may be approximated as a plane layer.

PROPERTIES: Table A-6, water ($T_f = 292.5\text{K}$): $k = 0.602\text{ W/m}\cdot\text{K}$, $\nu = 1.02 \times 10^{-6}\text{ m}^2/\text{s}$, $Pr = 7.09$.

ANALYSIS: (a) With $Re_D \ll 282,000$ and $\bar{h} = q''_{hf} / (T_{s,hf} - T_\infty)$, Eq. (7.54) reduces to

$$\overline{Nu}_D = \frac{q''_{hf} D}{k(T_{s,hf} - T_\infty)} \approx 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \quad (1)$$

Substituting for D , $(T_{s,hf} - T_\infty)$, k and Pr ,

$$4.98 \times 10^{-4} q''_{hf} \approx 0.3 + 1.15 Re_D^{1/2}$$

or, with $Re_D^{1/2} = (D/\nu)^{1/2} V^{1/2} = 38.3 V^{1/2}$,

$$4.98 \times 10^{-4} q''_{hf} \approx 0.3 + 44.1 V^{1/2} \quad (2)$$

Substituting for q''_{hf} ,

$$V = 0.20\text{ m/s} \quad <$$

(b) For a fixed value of $T_{s,hf}$, the thermal resistance of the deposit reduces q''_{hf} . From the thermal circuit.

$$q''_{hf} = \frac{T_{s,hf} - T_\infty}{(1/\bar{h}) + (\delta/k_d)}$$

Using Eq. (1) to evaluate \bar{h} ,

Continued

PROBLEM 7.61 (Cont.)

$$\bar{h} \approx \frac{k}{(D + \delta)} \left\{ 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3} \right]^{1/4}} \right\}$$

where, with $V = 0.20 \text{ m/s}$, $\text{Re}_D = V(D + \delta)/\nu = 314$, we obtain

$$\bar{h} \approx \frac{0.602 \text{ W/m} \cdot \text{K}}{0.0016 \text{ m}} \{20.7\} = 7,780 \text{ W/m}^2 \cdot \text{K}$$

Hence,
$$q_{\text{hf}}'' = \frac{5^\circ\text{C}}{\left(1.285 \times 10^{-4} + 0.5 \times 10^{-4} \right) \text{ m}^2 \cdot \text{K/W}} = 2.80 \times 10^4 \text{ W/m}^2 <$$

With the foregoing heat flux applied to the sensor and use of the model for Part (a), the sensor would indicate a velocity predicted from Eq. (2), or

$$V = \left[\left(4.98 \times 10^{-4} \times 2.80 \times 10^4 - 0.3 \right) / 44.1 \right]^2 = 0.096 \text{ m/s}$$

The error in the velocity measurement is therefore

$$\% \text{ Error} = \frac{V_{(a)} - V_{(b)}}{V_{(a)}} (100\%) = \frac{0.20 - 0.096}{0.20} \times 100 = 52\% <$$

COMMENTS: (1) The accuracy of the hot-film sensor is strongly influenced by the deposit, and in any such application it is important to maintain a clean surface. (2) The Reynolds numbers are much less than 282,000 and assumption 5 is valid.

PROBLEM 7.62

KNOWN: Long coated plastic, 20-mm diameter rod, initially at a uniform temperature of $T_i = 25^\circ\text{C}$, is suddenly exposed to the cross-flow of air at $T_\infty = 350^\circ\text{C}$ and $V = 50\text{ m/s}$.

FIND: (a) Time for the surface of the rod to reach 175°C , the temperature above which the special coating cures, and (b) Compute and plot the time-to-reach 175°C as a function of air velocity for $5 \leq V \leq 50\text{ m/s}$.

SCHEMATIC:

ASSUMPTIONS: (a) One-dimensional, transient conduction in the rod, (2) Constant properties, and (3) Evaluate thermophysical properties at $T_f = [(T_s + T_i)/2 + T_\infty]/2 = [(175 + 25)/2 + 350]^\circ\text{C}/2 = 225^\circ\text{C} = 500\text{ K}$.

PROPERTIES: Rod (Given): $\rho = 2200\text{ kg/m}^3$, $c = 800\text{ J/kg}\cdot\text{K}$, $k = 1\text{ W/m}\cdot\text{K}$, $\alpha = k/\rho c = 5.68 \times 10^{-7}\text{ m}^2/\text{s}$; Table A.4, Air ($T_f \approx 500\text{ K}$, 1 atm): $\nu = 38.79 \times 10^{-6}\text{ m}^2/\text{s}$, $k = 0.0407\text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.684$.

ANALYSIS: (a) To determine whether the lumped capacitance method is valid, determine the Biot number

$$\text{Bi}_{lc} = \frac{\bar{h}(r_o/2)}{k} \quad (1)$$

The convection coefficient can be estimated using the Churchill-Bernstein correlation, Eq. 7.57,

$$\begin{aligned} \overline{\text{Nu}}_D &= \frac{\bar{h}D}{k} = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5} \\ \text{Re}_D &= \frac{VD}{\nu} = 50\text{ m/s} \times 0.020\text{ m} / 38.79 \times 10^{-6}\text{ m}^2/\text{s} = 25,780 \\ \bar{h} &= \frac{0.0407\text{ W/m}\cdot\text{K}}{0.020\text{ m}} \left\{ 0.3 + \frac{0.62(25,780)^{1/2} (0.684)^{1/3}}{\left[1 + (0.4/0.684)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{25,780}{282,000}\right)^{5/8}\right]^{4/5} \right\} = 184\text{ W/m}^2\cdot\text{K} \quad (2) \end{aligned}$$

Substituting for \bar{h} from Eq. (2) into Eq. (1), find

$$\text{Bi}_{lc} = 184\text{ W/m}^2\cdot\text{K} (0.010\text{ m}/2) / 1\text{ W/m}\cdot\text{K} = 0.92 \gg 0.1$$

Hence, the lumped capacitance method is inappropriate. Using the one-term series approximation, Section 5.6.2, Eqs. 5.49 with Table 5.1,

$$\theta^* = C_1 \exp(-\zeta_1^2 \text{Fo}) J_0(\zeta_1 r^*) \quad r^* = r/r_o = 1$$

$$\theta^* = \frac{T(r_o, t) - T_\infty}{T_i - T_\infty} = \frac{(175 - 350)^\circ\text{C}}{(25 - 350)^\circ\text{C}} = 0.54$$

$$\text{Bi} = \bar{h}r_o/k = 1.84 \quad \zeta_1 = 1.546\text{ rad} \quad C_1 = 1.318$$

Continued...

PROBLEM 7.62 (Cont.)

$$0.54 = 1.318 \exp[-(1.546 \text{ rad})^2 \text{Fo}] J_0(1.546 \times 1)$$

Using Table B.4 to evaluate $J_0(1.546) = 0.4859$, find $\text{Fo} = 0.0725$ where

$$\text{Fo} = \frac{\alpha t_o}{r_o^2} = \frac{5.68 \times 10^{-7} \text{ m}^2/\text{s} \times t_o}{(0.010 \text{ m})^2} = 5.68 \times 10^{-3} t_o \quad (6)$$

$$t_o = 12.8 \text{ s}$$

<

(b) Using the *IHT Model, Transient Conduction, Cylinder*, and the *Tool, Correlations, External Flow, Cylinder*, results for the time-to-reach a surface temperature of 175°C as a function of air velocity V are plotted below.

COMMENTS: (1) Using the *IHT Tool, Correlations, External Flow, Cylinder*, the effect of the film temperature T_f on the estimated convection coefficient with $V = 50 \text{ m/s}$ can be readily evaluated.

$T_f \text{ (K)}$	460	500	623
$\bar{h} \text{ (W/m}^2\cdot\text{K)}$	187	184	176

At early times, $\bar{h} = 184 \text{ W/m}^2\cdot\text{K}$ is a good estimate, while as the cylinder temperature approaches the airstream temperature, the effect starts to be noticeable (10% decrease).

(2) The IHT analysis performed for part (b) was developed in two parts. Using a known value for \bar{h} , the *Transient Conduction, Cylinder Model* was tested. Separately, the *Correlation Tools* was assembled and tested. Then, the two files were merged to give the workspace for determining the time-to-reach 175°C as a function of velocity V .

PROBLEM 7.63

KNOWN: Velocity, diameter, initial temperature and properties of extruded wire. Temperature and velocity of air. Temperature of surroundings.

FIND: (a) Differential equation for temperature distribution $T(x)$, (b) Exact solution for negligible radiation and corresponding value of temperature at prescribed length of wire, (c) Effect of radiation on temperature of wire at prescribed length. Effect of wire velocity and emissivity on temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible variation of wire temperature in radial direction, (2) Negligible effect of axial conduction along the wire, (3) Constant properties, (4) Radiation exchange between small surface and large enclosure, (5) Motion of wire has a negligible effect on the convection coefficient ($V_e \ll V$).

PROPERTIES: Prescribed. Copper: $\rho = 8900 \text{ kg/m}^3$, $c_p = 400 \text{ J/kg} \cdot \text{K}$, $\varepsilon = 0.55$. Air:

$k = 0.037 \text{ W/m} \cdot \text{K}$, $\nu = 3 \times 10^{-5} \text{ m}^2/\text{s}$, $\text{Pr} = 0.69$.

ANALYSIS: (a) Applying conservation of energy to a stationary control surface, through which the wire moves, steady-state conditions exist and $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$. Hence, with *inflow* due to *advection* and *outflow* due to *advection*, *convection* and *radiation*,

$$\begin{aligned} \rho V_e A_c c_p T - \rho V_e A_c c_p (T + dT) - dq_{\text{conv}} - dq_{\text{rad}} &= 0 \\ -\rho V_e \left(\pi D^2 / 4 \right) c_p dT - \pi D dx \left[\bar{h} (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] &= 0 \\ \frac{dT}{dx} &= -\frac{4}{\rho V_e D c_p} \left[\bar{h} (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] \quad (1) < \end{aligned}$$

Alternatively, if the control surface is fixed to the wire, conditions are transient and the energy balance is of the form, $-\dot{E}_{\text{out}} = \dot{E}_{\text{st}}$, or

$$\begin{aligned} -\pi D dx \left[\bar{h} (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] &= \rho \left(\frac{\pi D^2}{4} dx \right) c_p \frac{dT}{dt} \\ \frac{dT}{dt} &= -\frac{4}{\rho D c_p} \left[\bar{h} (T - T_\infty) + \varepsilon \sigma (T^4 - T_{\text{sur}}^4) \right] \end{aligned}$$

Dividing the left- and right-hand sides of the equation by dx/dt and $V_e = dx/dt$, respectively, Eq. (1) is obtained.

(b) Neglecting radiation, separating variables and integrating, Eq. (1) becomes

$$\int_{T_i}^T \frac{dT}{T - T_\infty} = -\frac{4\bar{h}}{\rho V_e D c_p} \int_0^x dx$$

Continued

PROBLEM 7.63 (Cont.)

$$\ln\left(\frac{T - T_\infty}{T_i - T_\infty}\right) = -\frac{4\bar{h}x}{\rho V_e D c_p}$$

$$T = T_\infty + (T_i - T_\infty) \exp\left(-\frac{4\bar{h}x}{\rho V_e D c_p}\right) \quad (2) \quad <$$

With $Re_D = VD/\nu = 5 \text{ m/s} \times 0.005 \text{ m} / 3 \times 10^{-5} \text{ m}^2/\text{s} = 833$, the Churchill-Bernstein correlation yields

$$\overline{Nu}_D = 0.3 + \frac{0.62(833)^{1/2}(0.69)^{1/3}}{\left[1 + (0.4/0.69)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{833}{282,000}\right)^{5/8}\right]^{4/5} = 14.4$$

$$\bar{h} = \frac{k}{D} \overline{Nu}_D = \frac{0.037 \text{ W/m} \cdot \text{K}}{0.005 \text{ m}} 14.4 = 107 \text{ W/m}^2 \cdot \text{K}$$

Hence, applying Eq. (2) at $x = L$,

$$T_o = 25^\circ\text{C} + (575^\circ\text{C}) \exp\left(-\frac{4 \times 107 \text{ W/m}^2 \cdot \text{K} \times 5 \text{ m}}{8900 \text{ kg/m}^3 \times 0.2 \text{ m/s} \times 0.005 \text{ m} \times 400 \text{ J/kg} \cdot \text{K}}\right)$$

$$T_o = 340^\circ\text{C} \quad <$$

(c) Using the DER function of IHT, Eq. (1) may be numerically integrated from $x = 0$ to $x = L = 5.0 \text{ m}$ to obtain

$$T_o = 309^\circ\text{C} \quad <$$

Hence, radiation makes a discernable contribution to cooling of the wire. IHT was also used to obtain the following distributions.

The speed with which the wire is drawn from the extruder has a significant influence on the temperature distribution. The temperature decay decreases with increasing V_e due to the increasing effect of advection on energy transfer in the x direction. The effect of the surface emissivity is less pronounced, although, as expected, the temperature decay becomes more pronounced with increasing ϵ .

COMMENTS: (1) A critical parameter in wire extrusion processes is the *coiling temperature*, that is, the temperature at which the wire may be safely coiled for subsequent storage or shipment. The larger the production rate (V_e), the longer the cooling distance needed to achieve a desired coiling temperature. (2) Cooling may be enhanced by increasing the cross-flow velocity, and the specific effect of V may also be explored.

PROBLEM 7.64

KNOWN: Experimental apparatus comprised of a flat plate subjected to an airstream in parallel flow. Electrical patch heater on backside dissipates 15.5 W for all conditions. Pin fins fabricated from brass with prescribed diameter and length can be firmly attached to the plate. Fin tip and base temperatures observed for five different configurations (N, number of fins).

FIND: (a) The thermal resistance between the plate and airstream for the five configurations, (b) Model of the plate-fin system using appropriate convection correlations to predict the thermal resistances for the five configurations; compare predictions and observations; explain differences, and (b) Predict thermal resistances when the airstream velocity is doubled.

SCHEMATIC:

Experimental observations:	N	T_{tip} (°C)	T_s (°C)
	0	--	70.2
	1	40.6	67.4
	2	39.5	64.7
	5	36.4	57.4
	8	34.2	52.1

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible effect of flow interactions between pins, (3) Negligible radiation exchange with surroundings, (4) All heater power is transferred to airstream, and (5) Constant properties.

PROPERTIES: Table A.4, Air ($T_f = 310$ K, 1 atm): $k = 0.0270$ W/m·K, $\nu = 1.69 \times 10^{-5}$ m²/s, $Pr = 0.706$; Table A.1, Brass ($T = 300$ K): $k = 110$ W/m·K.

ANALYSIS: (a) The thermal resistance between the plate and the airstream is defined as

$$R_{tot} = \frac{T_s - T_\infty}{q} \quad (1)$$

The heat rate is 15.5 W for all configurations and using T_s values from the above table with $T_\infty = 20^\circ\text{C}$, find

Continued...

PROBLEM 7.64 (Cont.)

N	0	1	2	5	8	
R _{tot} (K/W)	3.24	3.06	2.88	2.41	2.07	<

(b) The thermal resistance of the plate-fin system can be expressed as

$$R_{\text{tot}} = [1/R_{\text{base}} + N/R_{\text{fin}}]^{-1} \quad (2)$$

where the thermal resistance of the exposed portion of the base, A_b , is

$$R_{\text{base}} = \frac{1}{\bar{h}_b A_b} \quad (3)$$

$$A_b = A_s - NA_c \quad (4)$$

where A_c is the cross-sectional area of a fin and A_s is the plate surface area. Approximating the airstream over the plate as parallel flow over a plate, use the *IHT Correlation Tool, External Flow, Flat Plate* assuming the flow is turbulent by the leading edge, to find

$$\bar{h}_b = 51 \text{ W/m}^2 \cdot \text{K}.$$

From the experimental observation with no fins ($N = 0$), the convection coefficient was measured as

$$\bar{h}_{b,\text{exp}} = \frac{q}{A_s (T_s - T_\infty)} = \frac{15.5 \text{ W}}{(0.0259 \text{ m})^2 (70.2 - 20)^\circ \text{C}} = 460 \text{ W/m}^2 \cdot \text{K}$$

Since the predicted coefficient is nearly an order of magnitude lower, we chose to use the experimental value in our subsequent analyses to predict overall system thermal resistance.

Approximating the airstream over a pin fin as cross-flow over a cylinder, use the *IHT Correlation Tool, External Flow, Cylinder* to find

$$\bar{h}_{\text{fin}} = 118 \text{ W/m}^2 \cdot \text{K}.$$

Using the *IHT Extended Surface Model* for the *Rectangular Pin Fin (Temperature Distribution and Heat Rate)* with a convection tip condition, the following fin thermal resistance was found as

$$R_{\text{fin}} = 25.4 \text{ K/W}$$

Using the foregoing values for R_{fin} and \bar{h}_b , the thermal resistances of the plate-fin system are tabulated below.

N	0	1	2	4	8	<
R _{base} (K/W)	3.241	3.331	3.426	3.746	4.133	
R _{fin} (K/W)	--	25.4	12.7	5.08	3.18	
R _{tot} (K/W)	3.24	2.95	2.70	2.16	1.80	

By comparison with the experimental results of part (a), note that we assured agreement for the $N = 0$ condition by using the measured rather than estimated (correlation) convection coefficient. The predicted thermal resistances are systematically lower than the experimental values, with the worst case ($N = 8$) being 13% lower.

Continued...

PROBLEM 7.64 (Cont.)

(c) The effect of doubling the velocity, from $u_\infty = 6$ to 12 m/s, will cause the fin convection coefficient to increase from $\bar{h}_{\text{fin}} = 118$ to 169 W/m²·K. For the base convection coefficient, we'll assume the flow is fully turbulent so that $\bar{h} \sim (u_\infty)^{0.8}$ according to Eq. 7.38, hence

$$\bar{h}_b(12 \text{ m/s}) = \bar{h}_b(6 \text{ m/s}) \left(\frac{12}{6} \right)^{0.8} = 460 \text{ W/m}^2 \cdot \text{K} (2)^{0.8} = 800 \text{ W/m}^2 \cdot \text{K}$$

Using the same procedure as above, find

N	0	1	2	4	8
R_{base} (K/W)	1.863	1.915	1.970	2.154	2.376
R_{fin} (K/W)	--	18.96	9.480	4.740	2.370
R_{tot} (K/W)	1.86	1.74	1.63	1.48	1.19

The effect of doubling the airstream velocity is to reduce the thermal resistance by approximately 35%.

PROBLEM 7.65

KNOWN: Dimensions of aluminum heat sink and enclosure on which it sits. Temperature of air flow normal to one face of heat sink. Power dissipation within enclosure.

FIND: Air velocity needed to maintain specified temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Convection coefficients on surfaces 2 and 3 are for flow past a flat plate, (2) Convection coefficient on surface 1 is for a noncircular cylinder in cross flow, (3) Negligible heat transfer from back surface (to left above), (4) All the electric power is dissipated by the heat sink, (5) Fin surfaces are isothermal at base temperature.

PROPERTIES: Given. Aluminum; $k_{hs} = 180 \text{ W/m}\cdot\text{K}$. Air; $k_a = 0.027 \text{ W/m}\cdot\text{K}$, $\nu_a = 16.4 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr_a = 0.706$.

ANALYSIS: We analyze each surface separately.

Surface 1. We use Equation 7.52 with C and m taken from Table 7.3 and $D_1 = L_e + L_b + L_f = 70 \text{ mm}$. Thus

$$h_1 = \frac{k_a}{D_1} (0.228 Re_1^{0.731} Pr_a^{1/3})$$

where $Re_1 = u_\infty D_1 / \nu_a$

and then, neglecting heat loss from the enclosure,

$$q_1 = h_1 A_1 (T_b - T_\infty) = h_1 (L_b + L_f) w_2 (T_b - T_\infty) = C_1 u_\infty^{0.731}$$

where

$$\begin{aligned} C_1 &= \frac{k_a}{D_1} 0.228 \left(\frac{D_1}{\nu_a} \right)^{0.731} Pr_a^{1/3} (L_b + L_f) w_2 (T_b - T_\infty) \\ &= \frac{0.027 \text{ W/m}\cdot\text{K}}{0.07 \text{ m}} \times 0.228 \times \left(\frac{0.07 \text{ m}}{16.4 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{0.731} \times (0.706)^{1/3} \times 0.06 \text{ m} \times 0.1 \text{ m} \times (70^\circ\text{C} - 20^\circ\text{C}) \\ &= 10.6 \text{ W}\cdot\text{s}^{0.731}/\text{m}^{0.731} \end{aligned}$$

Surface 2. We use Equation 7.31 again, assuming the flow is laminar, with $x = w_1$.

$$h_2 = \frac{k_a}{w_1} (0.664 Re_2^{1/2} Pr_a^{1/3})$$

Continued....

PROBLEM 7.65 (Cont.)

where $Re_2 = u_\infty w_1 / \nu_a$

and then $q_2 = h_2 A_2 (T_b - T_\infty) = h_2 2L_b w_1 (T_b - T_\infty) = C_2 u_\infty^{1/2}$

where

$$\begin{aligned} C_2 &= \frac{k_a}{w_1} 0.664 \left(\frac{w_1}{\nu_a} \right)^{1/2} Pr_a^{1/3} 2L_b w_1 (T_b - T_\infty) \\ &= \frac{0.027 \text{ W/m} \cdot \text{K}}{0.1 \text{ m}} \times 0.664 \times \left(\frac{0.1 \text{ m}}{16.4 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{1/2} \times (0.706)^{1/3} \times 2 \times 0.01 \text{ m} \times 0.1 \text{ m} \times (70^\circ\text{C} - 20^\circ\text{C}) \\ &= 1.25 \text{ W} \cdot \text{s}^{1/2} / \text{m}^{1/2} \end{aligned}$$

Surface 3. We use Equation 7.31 again, assuming the flow is laminar and the boundary layers restart on each leading edge. We have $x = t$, so

$$h_3 = \frac{k_a}{t} (0.664 Re_3^{1/2} Pr_a^{1/3})$$

where $Re_3 = u_\infty t / \nu_a$

and then $q_3 = h_3 A_3 (T_b - T_\infty) = h_3 6t (2L_f + w_2) (T_b - T_\infty) = C_3 u_\infty^{1/2}$

where

$$\begin{aligned} C_3 &= \frac{k_a}{t} 0.664 \left(\frac{t}{\nu_a} \right)^{1/2} Pr_a^{1/3} 6t (2L_f + w_2) (T_b - T_\infty) \\ &= \frac{0.027 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} \times 0.664 \times \left(\frac{0.01 \text{ m}}{16.4 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{1/2} \times (0.706)^{1/3} \times 6 \times 0.01 \text{ m} \\ &\quad \times (2 \times 0.05 \text{ m} + 0.1 \text{ m}) \times (70^\circ\text{C} - 20^\circ\text{C}) \\ &= 23.7 \text{ W} \cdot \text{s}^{1/2} / \text{m}^{1/2} \end{aligned}$$

Now $q = q_1 + q_2 + q_3 = C_1 u_\infty^{0.731} + (C_2 + C_3) u_\infty^{1/2} = 70 \text{ W}$

Solving this implicit equation for u_∞ yields

$$u_\infty = 3.26 \text{ m/s}$$

We now check that the Reynolds numbers are in the proper range.

$$Re_1 = u_\infty D_1 / \nu_a = 3.26 \text{ m/s} \times 0.07 \text{ m} / 16.4 \times 10^{-6} \text{ m}^2/\text{s} = 1.39 \times 10^4$$

This is in the correct range in Table 7.3.

$$Re_2 = u_\infty w_1 / \nu_a = 3.26 \text{ m/s} \times 0.1 \text{ m} / 16.4 \times 10^{-6} \text{ m}^2/\text{s} = 1.99 \times 10^4$$

which is laminar as assumed.

$$Re_3 = u_\infty t / \nu_a = 1.99 \times 10^3$$

which is laminar as assumed.

COMMENTS: (1) Of the 70 W dissipated through the heat sink, 25 W are dissipated from surface 1, 2 W from surface 2, and 43 W from surface 3. The fin tips and sides are subject to high heat transfer coefficients because the boundary layer restarts on each leading edge. (2) Since we have neglected heat transfer from the inner surfaces of the heat sink, the fins are not behaving as fins but simply as conductors. We can estimate the temperature drop along the fin by equating the heat conducting along it to the heat leaving the tip by convection: $k_{fs}(T_b - T_t)/L_f = h_3(T_t - T_\infty)$. The result is $T_t = 69^\circ\text{C}$. Therefore the assumption of isothermal fins was reasonable. (3) In reality, the flow in this configuration is very complex and the wise engineer would perform experiments or use a computational fluid dynamics code to assess the thermal performance of the heat sink. (4) Heat sinks equipped with pin fins are often preferred since they exhibit less sensitivity to the direction of flow of the coolant.

PROBLEM 7.66

KNOWN: Temperature and velocity of air flow over a sphere of prescribed surface temperature and diameter.

FIND: (a) Drag force, (b) Heat transfer rate with air velocity of 25 m/s; and (c) Compute and plot the heat rate as a function of air velocity for the range $1 \leq V \leq 25$ m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation exchange with surroundings.

PROPERTIES: Table A.4, Air ($T_\infty = 298$ K, 1 atm): $\mu = 184 \times 10^{-7}$ N·s/m²; $\nu = 15.71 \times 10^{-6}$ m²/s, $k = 0.0261$ W/m·K, $Pr = 0.71$; ($T_s = 348$ K): $\mu = 208 \times 10^{-7}$ N·s/m²; ($T_f = 323$ K): $\nu = 18.2 \times 10^{-6}$ m²/s, $\rho = 1.085$ kg/m³.

ANALYSIS: (a) Working with properties evaluated at T_f

$$Re_D = \frac{VD}{\nu} = \frac{25 \text{ m/s}(0.01 \text{ m})}{18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 1.37 \times 10^4$$

and from Fig. 7.8, find $C_D \approx 0.4$. Hence

$$F_D = C_D \left(\pi D^2 / 4 \right) \left(\rho V^2 / 2 \right) = 0.4 (\pi/4) (0.01 \text{ m})^2 1.085 \text{ kg/m}^3 (25 \text{ m/s})^2 / 2 = 0.011 \text{ N} <$$

(b) With

$$Re_D = \frac{VD}{\nu} = \frac{25 \text{ m/s}(0.01 \text{ m})}{15.71 \times 10^{-6} \text{ m}^2/\text{s}} = 1.59 \times 10^4$$

it follows from the Whitaker relation that

$$\begin{aligned} \overline{Nu}_D &= 2 + \left[0.4 Re_D^{1/2} + 0.06 Re_D^{2/3} \right] Pr^{0.4} \left(\frac{\mu}{\mu_s} \right)^{1/4} \\ \overline{Nu}_D &= 2 + \left[0.4 (1.59 \times 10^4)^{1/2} + 0.06 (1.59 \times 10^4)^{2/3} \right] (0.71)^{0.4} \left(\frac{184}{208} \right)^{1/4} = 76.7 \end{aligned}$$

Hence, the convection coefficient and convection heat rate are

$$\bar{h} = \overline{Nu}_D \frac{k}{D} = 76.7 \frac{0.0261 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} = 200 \text{ W/m}^2 \cdot \text{K}$$

$$q = \bar{h} \pi D^2 (T_s - T_\infty) = 200 \text{ W/m}^2 \cdot \text{K} \times \pi (0.01 \text{ m})^2 (75 - 25)^\circ \text{C} = 3.14 \text{ W} <$$

Ts = 75 + 273 // Surface temperature, K
V = 25 // Airstream velocity, m/s
Tinf = 25 + 273 // Airstream temperature, K
```

PROBLEM 7.67

KNOWN: Sphere with a diameter of 20 mm and a surface temperature of 60°C that is immersed in a fluid at a temperature of 30°C with a velocity of 2.5 m/s.

FIND: The drag force and the heat rate when the fluid is (a) water and (b) air at atmospheric pressure. Explain why the results for the two fluids are so different.

SCHEMATIC:

ASSUMPTIONS: (1) Flow over a smooth sphere, (2) Constant properties.

PROPERTIES: Table A-6, Water ($T_\infty = 30^\circ\text{C} = 303\text{ K}$): $\mu = 8.034 \times 10^{-4}\text{ N}\cdot\text{s}/\text{m}^2$, $\nu = 8.068 \times 10^{-7}\text{ m}^2/\text{s}$, $k = 0.6172\text{ W}/\text{m}\cdot\text{K}$, $\text{Pr} = 5.45$; Water ($T_s = 333\text{ K}$): $\mu_s = 4.674 \times 10^{-4}\text{ N}\cdot\text{s}/\text{m}^2$; Table A-4, Air ($T_\infty = 30^\circ\text{C} = 303\text{ K}$, 1 atm): $\mu = 1.86 \times 10^{-5}\text{ N}\cdot\text{s}/\text{m}^2$, $\nu = 1.619 \times 10^{-5}\text{ m}^2/\text{s}$, $k = 0.0265\text{ W}/\text{m}\cdot\text{K}$, $\text{Pr} = 0.707$; Air ($T_\infty = 333\text{ K}$): $\mu_s = 2.002 \times 10^{-5}\text{ N}\cdot\text{s}/\text{m}^2$.

ANALYSIS: The drag force, F_D , for the sphere is determined from the drag coefficient, Eq. 7.50,

$$C_D = \frac{F_D}{A_f \left(\rho V^2 / 2 \right)}$$

where $A_f = \pi D^2 / 4$ is the frontal area. C_D is a function of the Reynolds number $\text{Re}_D = VD/\nu$ as represented in Figure 7.8. For the convection rate equation,

$$q = \bar{h}_D A_s (T_s - T_\infty)$$

where $A_s = \pi D^2$ is the surface area and the convection coefficient is estimated using the Whitaker correlation, Eq. 7.56,

$$\overline{\text{Nu}}_D = 2 + \left[0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right] \text{Pr}^{0.4} (\mu / \mu_s)^{1/4}$$

where all properties except μ_s are evaluated at T_∞ . For convenience we will evaluate properties required for the drag force at T_∞ . The results of the analyses for the two fluids are tabulated below.

Fluid	Re_D	C_D	$F_D\text{ (N)}$	$\overline{\text{Nu}}_D$	$\bar{h}_D\text{ (W/m}^2\cdot\text{K)}$	$q\text{ (W)}$
water	6.198×10^4	0.5	0.489	439	13,540	510
air	3.088×10^3	0.4	0.452×10^{-3}	31.9	42.3	1.59

The frontal and surface areas, respectively, are $A_f = 3.142 \times 10^{-4}\text{ m}^2$ and $A_s = 1.257 \times 10^{-3}\text{ m}^2$.

COMMENTS: The Reynolds number is the ratio of inertia to viscous forces. We associate higher viscous shear and heat transfer with larger Reynolds numbers. The drag force also depends upon the fluid density, which further explains why F_D for water is much larger, by a factor of 1000, than for air.

$\overline{\text{Nu}}_D$ is dependent upon Re_D^n where n is $1/2$ to $2/3$, and represents the dimensionless temperature gradient at the surface. Since the thermal conductivity of water is nearly 20 times that of air, we expect a significant difference between \bar{h}_D and q for the two fluids.

PROBLEM 7.68

KNOWN: Conditions associated with airflow over a spherical light bulb of prescribed diameter and surface temperature.

FIND: Heat loss by convection.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature.

PROPERTIES: Table A-4, Air ($T_\infty = 25^\circ\text{C}$, 1 atm): $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0261 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.71$, $\mu = 183.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$; Table A-4, Air ($T_s = 140^\circ\text{C}$, 1 atm): $\mu = 235.5 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$.

ANALYSIS: The heat rate by convection is

$$q = \bar{h}(\pi D^2) (T_s - T_\infty)$$

where \bar{h} may be estimated from the Whitaker relation

$$\bar{h} = \frac{k}{D} \left[2 + \left(0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Pr}^{0.4} \left(\mu / \mu_s \right)^{1/4} \right]$$

where

$$\text{Re}_D = \frac{VD}{\nu} = \frac{0.5 \text{ m/s} \times 0.05 \text{ m}}{15.71 \times 10^{-6} \text{ m}^2/\text{s}} = 1591.$$

Hence,

$$\bar{h} = \frac{0.0261 \text{ W/m}\cdot\text{K}}{0.05 \text{ m}} \left\{ 2 + \left[0.4(1591)^{1/2} + 0.06(1591)^{2/3} \right] (0.71)^{0.4} \left(\frac{183.6}{235.5} \right)^{1/4} \right\}$$

$$\bar{h} = 11.4 \text{ W/m}^2 \cdot \text{K}$$

and the heat rate is

$$q = 11.4 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \pi (0.05 \text{ m})^2 (140 - 25)^\circ\text{C} = 10.3 \text{ W.} \quad <$$

COMMENTS: (1) The low value of \bar{h} suggests that heat transfer by free convection may be significant and hence that the total loss by convection exceeds 10.3 W.

(2) The surface of the bulb also dissipates heat to the surrounding by radiation. Further, in an actual light bulb, there is also heat loss by conduction through the socket.

PROBLEM 7.69

KNOWN: Diameter, properties and initial temperature of niobium sphere. Velocity and temperature of nitrogen. Temperature of surroundings.

FIND: (a) Time for sphere to cool to prescribed temperature if radiation is neglected, (b) Cooling time if radiation is considered. Effect of flow velocity.

SCHEMATIC:

ASSUMPTIONS: (1) Lumped capacitance method is valid, (2) Constant properties, (3) Radiation exchange with large surroundings.

PROPERTIES: Table A-4, nitrogen ($T_\infty = 298\text{K}$): $\mu = 177 \times 10^{-7} \text{ N} \cdot \text{s} / \text{m}^2$, $\nu = 15.7 \times 10^{-6} \text{ m}^2 / \text{s}$, $k = 0.0257 \text{ W} / \text{m} \cdot \text{K}$, $\text{Pr} = 0.716$. Table A-4, nitrogen ($\bar{T}_s = 873\text{K}$): $\mu_s = 368 \times 10^{-7} \text{ N} \cdot \text{s} / \text{m}^2$.

ANALYSIS: (a) Neglecting radiation, the cooling time may be determined from Eq. (5.5),

$$t = \frac{\rho(\pi D^3/6)c}{\bar{h}\pi D^2} \ln \frac{\theta_i}{\theta} = \frac{\rho c D}{6\bar{h}} \ln \frac{T_i - T_\infty}{T_f - T_\infty}$$

The convection coefficient is obtained from the Whitaker correlation with $\text{Re}_D = VD/\nu$

$= 5 \text{ m/s} \times 0.01 \text{ m} / 15.7 \times 10^{-6} \text{ m}^2 / \text{s} = 3185$. Hence,

$$\text{Nu}_D = (\bar{h}D/k) = 2 + \left(0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Pr}^{0.4} (\mu/\mu_s)^{1/4}$$

$$\bar{h} = \frac{0.0257 \text{ W} / \text{m} \cdot \text{K}}{0.01 \text{ m}} \left\{ 2 + \left[0.4(3185)^{1/2} + 0.06(3185)^{2/3} \right] (0.716)^{0.4} \left(\frac{177}{368} \right)^{0.25} \right\} = 71.8 \text{ W} / \text{m}^2 \cdot \text{K}$$

$$t = \frac{8600 \text{ kg} / \text{m}^3 \times 290 \text{ J} / \text{kg} \cdot \text{K} \times 0.01 \text{ m}}{6 \times 71.8 \text{ W} / \text{m}^2 \cdot \text{K}} \ln \frac{(900 - 25)}{(300 - 25)} = 67 \text{ s} \quad <$$

(b) If the effect of radiation is considered, the cooling time can be obtained by integrating Eq. (5.15).

With $A_s/V = \pi D^2/(\pi D^3/6) = 6/D$, the appropriate form of the equation is

$$\frac{dT}{dt} = -\frac{6}{\rho c D} \left[\bar{h}(T - T_\infty) + \epsilon \sigma (T^4 - T_{\text{sur}}^4) \right]$$

Using the DER function of IHT to integrate this equation over the limits from $T_i = 1173\text{K}$ to

$T_f = 573\text{K}$, we obtain

$$t = 48 \text{ s} \quad <$$

Continued

PROBLEM 7.69 (Cont.)

For $V = 1.0$ and 25.0 m/s, the cooling times are $t \approx 80$ and 24 s, respectively. Temperature histories for the three velocities are shown below.

COMMENTS: The cooling time is significantly affected by the flow velocity.

PROBLEM 7.70

KNOWN: An underwater instrument pod having a spherical shape with a diameter of 85 mm dissipating 300 W.

FIND: Estimate the surface temperature of the pod for these conditions: (a) when submersed in a bay where the water temperature is 15°C and the current is 1 m/s, and (b) after being hauled out of the water *without deactivating the power* and suspended in the ambient where the air temperature is 15°C and the wind speed is 3 m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Flow over a smooth sphere, (3) Uniform surface temperatures, (4) Negligible radiation heat transfer for air (a) condition, and (5) Constant properties.

PROPERTIES: Table A-6, Water ($T_\infty = 15^\circ\text{C} = 288 \text{ K}$): $\mu = 0.001053 \text{ N}\cdot\text{s}/\text{m}^2$, $\nu = 1.139 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.5948 \text{ W}/\text{m}\cdot\text{K}$, $\text{Pr} = 8.06$; Table A-4, Air ($T_\infty = 288 \text{ K}$, 1 atm): $\mu = 1.788 \times 10^{-5} \text{ N}\cdot\text{s}/\text{m}^2$, $\nu = 1.482 \times 10^{-5} \text{ m}^2/\text{s}$, $k = 0.02534 \text{ W}/\text{m}\cdot\text{K}$, $\text{Pr} = 0.710$; Air ($T_s = 945 \text{ K}$): $\mu_s = 4.099 \times 10^{-5} \text{ N}\cdot\text{s}/\text{m}^2$.

ANALYSIS: The energy balance for the submersed-in-water (w) and suspended-in-air (a) conditions are represented in the schematics above and have the form

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = -q_{cv} + P_e = 0 \quad (1)$$

$$-\bar{h}_D A_s (T_s - T_\infty) + P_e = 0$$

where $A_s = \pi D^2$ and \bar{h}_D is estimated using the Whitaker correlation, Eq. 7.56,

$$\overline{\text{Nu}}_D = 2 + \left[0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right] \text{Pr}^{0.4} (\mu / \mu_s)^{1/4} \quad (2)$$

where all properties except μ_s are evaluated at T_∞ . The results are tabulated below.

Condition	Re_D	$\overline{\text{Nu}}_D$	\bar{h}_D ($\text{W}/\text{m}^2\cdot\text{K}$)	T_s ($^\circ\text{C}$)
(w) water	7.465×10^4	499	3491	18.8
(a) air	1.72×10^4	67.5	20.1	672

COMMENTS: (1) While submerged and dissipating 300 W, the pod is safely operating at a temperature slightly above that of the water. When hauled from the water and suspended in air, the pod temperature increases to a destruction temperature (672°C). The pod gets smoked!

(2) The assumption that $\mu/\mu_s \approx 1$ is appropriate for the water (w) condition. For the air (a) condition, $\mu/\mu_s = 0.436$ and the final term of the correlation is significant. Recognize that radiation exchange with the surroundings for the air condition should be considered for an improved estimate.

Continued

PROBLEM 7.70 (Cont.)

(3) Why such a difference in T_s for the water (w) and air (a) conditions? From the results table note that the Re_D , Nu_D , and \bar{h}_D are, respectively, 4x, 7x and 170x times larger for water compared to air. Water, because of its thermophysical properties which drive the magnitude of \bar{h}_D , is a much better coolant than air for similar flow conditions.

```

/* Comment: Because Ts is much larger than Tinf for the in-air operation, the ratio of mu / mus
exceeds the limits for the correlation. Hence, a warning message comes with the IHT solution. */

PROBLEM 7.71

KNOWN: Method to manufacture small diameter lead solder balls. Properties of $D = 130\ \mu\text{m}$ diameter particles ejected into nitrogen gas at $V = 2\ \text{m/s}$. Nitrogen temperature and pressure, initial particle temperature. Piezoelectric device oscillation frequency.

FIND: (a) Terminal velocity of the droplets and distance traveled when a droplet completely solidifies, (b) Separation distance between droplets and pot size needed to produce solder balls continuously for one week.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible radiation heat transfer, (2) lumped capacitance thermal response.

PROPERTIES: Table A.4, Nitrogen: ($T_f \approx (T_i + T_\infty)/2 = (225^\circ\text{C} + 30^\circ\text{C})/2 = 127.5^\circ\text{C} \approx 400\ \text{K}$): $\rho = 0.8425\ \text{kg/m}^3$, $\nu = 26.16 \times 10^{-6}\ \text{m}^2/\text{s}$. ($\bar{T}_s = (225^\circ\text{C} + 183^\circ\text{C})/2 = 205^\circ\text{C} = 477\ \text{K}$): $\mu_s = 248 \times 10^{-7}\ \text{N}\cdot\text{s/m}^2$. ($T_\infty = 30^\circ\text{C} = 303\ \text{K}$): $\rho = 1.1233\ \text{kg/m}^3$, $\nu = 15.86 \times 10^{-6}\ \text{m}^2/\text{s}$, $k = 0.0259\ \text{W/m}\cdot\text{K}$, $\mu = 178 \times 10^{-7}\ \text{N}\cdot\text{s/m}^2$, $\text{Pr} = 0.716$.

ANALYSIS:

(a) A force balance on the particle yields

$$F_D = mg = \pi (D_p/2)^2 C_D \rho_f V^2/2 = \frac{4}{3} \pi (D_p/2)^3 \rho_p g$$

Which may be rearranged to yield

$$\begin{aligned} C_D &= \frac{4}{3} D_p (\rho_p / \rho_f) g / V^2 \\ C_D &= \frac{4}{3} \times 130 \times 10^{-6}\ \text{m} \times (8230/0.8425) \times 9.8\ \text{m/s}^2 / V^2 \\ C_D &= (16.59\ \text{m}^2/\text{s}^2) / V^2 \end{aligned} \tag{1}$$

and

Continued...

PROBLEM 7.71 (Cont.)

$$\begin{aligned} \text{Re}_D &= \frac{VD_p}{\nu} = V \times 130 \times 10^{-6} \text{ m} / 26.16 \times 10^{-6} \text{ m}^2/\text{s} \\ \text{Re}_D &= (4.97 \text{ s/m}) \times V \end{aligned} \quad (2)$$

Equations 1 and 2 may be solved for C_D and Re_D for any value of V . The resulting values of C_D and Re_D must be consistent with the results of Figure 7.8.

A trial-and-error solution yields $V = 2.03 \text{ m/s}$, $C_D = 4.03$, $\text{Re}_D = 10.09$ from solution of Equations 1 and 2. From Figure 7.8, at $\text{Re}_D = 10$, $C_D = 4$. Therefore $V \approx 2 \text{ m/s}$. \leftarrow

We note that the terminal velocity is identical to the injection velocity. Hence, the particles travel at constant velocity. The particle cooling process occurs in two steps.

Step One: Particle cooling to $T_f = 183^\circ\text{C}$.

With nitrogen properties evaluated at $T_\infty = 30^\circ\text{C}$, the Reynolds number is

$$\text{Re}_D = \frac{2 \text{ m/s} \times 130 \times 10^{-6} \text{ m}}{15.86 \times 10^{-6} \text{ m}^2/\text{s}} = 16.39$$

The Whitaker correlation yields

$$\overline{\text{Nu}}_D = 2 + \left[0.4\sqrt{16.39} + 0.06 \times 16.39^{2/3} \right] \times 0.716^{0.4} \times \left(\frac{178}{248} \right)^{1/4} = 3.62$$

Therefore

$$\bar{h}_D = \overline{\text{Nu}}_D k / D_p = 3.62 \times 0.0259 \text{ W/m} \cdot \text{K} / 130 \times 10^{-6} \text{ m} = 721 \text{ W/m}^2 \cdot \text{K}$$

Using Equation 5.6 with $A_s = 4\pi(D/2)^2 = 4 \times \pi \times (130 \times 10^{-6} \text{ m}/2)^2 = 53.1 \times 10^{-9} \text{ m}^2$,

$$V = (4/3) \pi (D/2)^3 = (4/3) \times \pi \times (130 \times 10^{-6} \text{ m}/2)^3 = 1.15 \times 10^{-12} \text{ m}^3,$$

$$\frac{T - T_\infty}{T_i - T_\infty} = \frac{183 - 30}{225 - 30} = 0.785 = \exp \left[- \left(\frac{721 \text{ W/m}^2 \cdot \text{K} \times 53.1 \times 10^{-9} \text{ m}^2}{8230 \text{ kg/m}^3 \times 1.15 \times 10^{-12} \text{ m}^3 \times 240 \text{ J/kg} \cdot \text{K}} \right) \times t_1 \right]$$

from which

$$t_1 = 14.3 \times 10^{-3} \text{ s}$$

Step Two: Particle solidification at $T_f = 183^\circ\text{C}$.

An energy balance on the particle during solidification yields

$$\dot{E}_{st} + \dot{E}_{out} = 0$$

or

$$-\dot{V} \rho_p h_{sf} - h A_s (T_f - T_\infty) t_2$$

or

$$t_2 = \frac{1.15 \times 10^{-12} \text{ m}^3 \times 8230 \text{ kg/m}^3 \times 42,000 \text{ J/kg}}{721 \text{ W/m}^2 \cdot \text{K} \times 53.1 \times 10^{-9} \text{ m}^2 \times (183 - 30)^\circ\text{C}} = 67.6 \times 10^{-3} \text{ s}$$

Therefore, the time to completely solidify is

Continued...

PROBLEM 7.71 (Cont.)

$$T = t_1 + t_2 = 14.3 \times 10^{-3} \text{ s} + 67.6 \times 10^{-3} \text{ s} = 82 \times 10^{-3} \text{ s} \quad <$$

(b) The distance that one particle travels is

$$L = (2 \text{ m/s}) / (1800 \text{ s}^{-1}) = 1.11 \text{ mm} \quad <$$

The required pot size for one week of operation is

$$\begin{aligned} \nabla_{\text{pot}} &= 1.15 \times 10^{-12} \text{ m}^3/\text{particle} \times 1800 \text{ particles/s} \times 7 \text{ days} \times 24 \text{ h/day} \times 3600 \text{ s/h} \\ \nabla_{\text{pot}} &= 1.25 \times 10^{-3} \text{ m}^3 \quad < \end{aligned}$$

COMMENTS: (1) The Biot number associated with the cooling of the particle is $Bi = h(D_p/6)/k_p = 721 \text{ W/m}^2\cdot\text{K} \times (130 \times 10^{-6} \text{ m/s}) / (38 \text{ W/m}\cdot\text{K}) = 0.0004 \ll 0.1$. Therefore, the lumped capacitance assumption is valid. (2) The maximum possible radiation heat transfer coefficient is associated with the initial particle temperature and an emissivity of unity. Assuming a surroundings temperature of $30^\circ\text{C} = 303 \text{ K}$, we find a radiation heat transfer coefficient of $h_r = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \times (498 + 303) \text{ K} \times (498^2 + 303^2) \text{ K}^2 = 15 \text{ W/m}^2\cdot\text{K}$. Therefore, radiation heat transfer is negligible. (3) The terminal velocity of the very small spherical particle is relatively low. This is because the surface area to weight ratio of a sphere is inversely proportional to the sphere diameter. As the sphere becomes small, drag forces become relatively large at relatively low velocities.

PROBLEM 7.72

KNOWN: A spherical workpiece of pure copper with a diameter of 15 mm and emissivity of 0.5 is suspended in a large furnace with walls at a uniform temperature of 600°C. The air flow over the workpiece has a temperature of 900°C with a velocity of 7.5 m/s.

FIND: (a) The steady-state temperature of the workpiece; (b) Estimate the time required for the workpiece to reach within 5°C of the steady-state temperature if its initial, uniform temperature is 25°C; (c) Estimate the steady-state temperature of the workpiece if the air velocity is doubled with all other conditions remaining the same; also, determine the time required for the workpiece to reach within 5°C of this value. Plot on the same graph the workpiece temperature histories for the two air velocity conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Flow over a smooth sphere, (2) Sphere behaves as spacewise isothermal object; lumped capacitance method is valid, (3) Sphere is small object in large, isothermal surroundings, and (4) Constant properties.

PROPERTIES: Table A-4, Air ($T_\infty = 1173$ K, 1 atm): $\mu = 4.665 \times 10^{-5}$ N·s/m², $\nu = 0.0001572$ m²/s, $k = 0.075$ W/m·K, $Pr = 0.728$; Air ($T_s = 1010$ K, 1 atm): $\mu_s = 4.268 \times 10^{-5}$ N·s/m².

ANALYSIS: (a) The steady-state temperature is determined from the energy balance on the sphere as represented in the schematic above.

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} &= 0 & -q_{cv} - q_{rad} + 0 &= 0 \\ -\bar{h}_D A_s (T_s - T_\infty) - \epsilon A_s \sigma (T_s^4 - T_{sur}^4) &= 0 \end{aligned} \quad (1)$$

where $A_s = \pi D^2/4$. The convection coefficient can be estimated using the Whitaker correlation, Eq. 7.56, where all properties except μ_s are evaluated at T_∞ . Assume $T_s = 737^\circ\text{C} = 1010$ K to evaluate μ_s .

$$\overline{Nu}_D = 2 + \left[0.4 Re_D^{1/2} + 0.06 Re_D^{2/3} \right] Pr^{0.4} (\mu/\mu_s)^{1/4} \quad (2)$$

See the table below for results of the correlation calculations. From the energy balance, canceling out A_s , with numerical values, find T_s .

$$-79.8 \text{ W/m}^2 \cdot \text{K} (T_s - 1173) \text{ K} - 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_s^4 - 873^4) \text{ K}^4 = 0$$

$$T_s = 1010 \text{ K} = 737^\circ\text{C}. \quad <$$

(b) The time required for the sphere initially at $T_i = 25^\circ\text{C}$ to reach within 5°C of the steady-state temperature can be determined from the energy balance for the transient condition.

Continued

PROBLEM 7.72 (Cont.)

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = \dot{E}_{\text{st}}$$

$$-\bar{h}_D A_s (T_s - T_\infty) - \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4) = \rho c \left(\pi D^3 / 6 \right) \frac{dT}{dt} \quad (3)$$

Recognize that \bar{h}_D is not constant, but depends upon $T_s(t)$. Using *IHT* to perform the integration, evaluate \bar{h}_D , and provide pure copper properties ρ and c as a function of T_s , the time t_0 for $T(t_0) = (737 - 5)^\circ\text{C} = 732^\circ\text{C}$ is

$$t_0 = 274 \text{ s}$$

See Comments 1 and 2 for details on the *IHT* calculation method.

(c) Use Eq. (1) and (2) to find the steady-state temperature when the air velocity is doubled, $V = 2 \times 7.5 \text{ m/s} = 15 \text{ m/s}$. The results are tabulated below along with those from part (a).

Part	V (m/s)	Re _D	$\overline{\text{Nu}}_D$	\bar{h}_D (W/m ² ·K)	T _s (°C)
a	7.5	715.6	15.96	79.8	737
b	15	1431	22.42	112.1	760

As expected, increasing the air velocity will cause the sphere temperature to increase toward T_∞ . Note that \bar{h}_D increases by a factor of 1.4 as the air velocity is doubled. From correlation Eq. (2) note that \bar{h}_D is approximately proportional to V^n where n is in the range 1/2 to 2/3. Using the *IHT* code for the lumped capacitance analysis, the time for $T(t_0) = (760 - 5)^\circ\text{C} = 755^\circ\text{C}$ is

$$t_0 = 230 \text{ s}$$

The temperature histories for the two air velocity conditions are calculated using the foregoing transient analyses in the *IHT* workspace.

Continued

PROBLEM 7.73

KNOWN: Diameter and initial and final temperatures of copper spheres quenched in a water bath.

FIND: (a) Terminal velocity in the bath, (b) Tank height.

SCHEMATIC:

ASSUMPTIONS: (1) Sphere descends at terminal velocity, (2) Uniform, but time varying surface, temperature.

PROPERTIES: Table A-1, Copper (350K): $\rho = 8933 \text{ kg/m}^3$, $k = 398 \text{ W/m}\cdot\text{K}$, $c_p = 387 \text{ J/kg}\cdot\text{K}$; Table A-6, Water ($T_\infty = 280 \text{ K}$): $\rho = 1000 \text{ kg/m}^3$, $\mu = 1422 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$, $k = 0.582 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 10.26$; ($T_s \approx 340 \text{ K}$): $\mu_s = 420 \times 10^{-5} \text{ N}\cdot\text{s/m}^2$.

ANALYSIS: A force balance gives $C_D \left(\pi D^2 / 4 \right) \rho V^2 / 2 = (\rho_{\text{cu}} - \rho) g \pi D^3 / 6$,

$$C_D V^2 = \frac{4D}{3} \frac{\rho_{\text{cu}} - \rho}{\rho} g = \frac{4 \times 0.02 \text{ m}}{3} \cdot \frac{8933 - 1000}{1000} 9.8 \text{ m/s}^2 = 2.07 \text{ m}^2 / \text{s}^2.$$

An iterative solution is needed, where C_D is obtained from Figure 7.8 with $\text{Re}_D = VD/\nu = 0.02 \text{ m} / (1.42 \times 10^{-6} \text{ m}^2/\text{s}) = 14,085$. Convergence is achieved with

$$V \approx 2.1 \text{ m/s} \quad <$$

for which $\text{Re}_D = 29,580$ and $C_D \approx 0.46$. Using the Whitaker expression

$$\overline{\text{Nu}}_D = 2 + \left(0.4 \times 29,580^{1/2} + 0.06 \times 29,580^{2/3} \right) (10.26)^{0.4} (1422/420)^{1/4} = 439$$

$$\bar{h} = \overline{\text{Nu}}_D k/D = 439 \times 0.582 \text{ W/m}\cdot\text{K} / 0.02 \text{ m} = 12,775 \text{ W/m}^2 \cdot \text{K}.$$

To determine applicability of lumped capacitance method, find $\text{Bi} = \bar{h}(r_o/3)/k_{\text{cu}} = 12,775$

$\text{W/m}^2 \cdot \text{K} (0.01 \text{ m}/3) / 398 \text{ W/m}\cdot\text{K} = 0.11$. Applicability is marginal. Using Eq. 5.50c,

$\theta_o^* = C_1 \exp(-\xi_1^2 \text{Fo})$ and from Table 5.1 at $\text{Bi} = \bar{h} r_o/k = 0.32$, $C_1 = 1.0937$, $\xi_1 = 0.9472$. Substituting into the preceding equation yields

$$0.5 = 1.0937 \exp(-0.9472^2 \text{Fo}) \text{ from which}$$

$$\text{Fo} = 0.87 = \alpha t_f / r_o^2$$

With $\alpha_{\text{cu}} = k/\rho c_p = 398 \text{ W/m}\cdot\text{K} / (8933 \text{ kg/m}^3)(387 \text{ J/kg}\cdot\text{K}) = 1.15 \times 10^{-4} \text{ m}^2/\text{s}$, find

$$t_f = 0.87 (0.01 \text{ m})^2 / 1.15 \times 10^{-4} \text{ m}^2/\text{s} = 0.76 \text{ s}.$$

Required tank height is

$$H = t_f \cdot V = 0.76 \text{ s} \times 2.1 \text{ m/s} = 1.6 \text{ m}. \quad <$$

COMMENTS: Note that the terminal velocity is not reached immediately. Reduced V implies reduced \bar{h} and increased t_f . The Fourier number, Fo , is greater than 0.2. Hence, use of Eq. 5.50c is justified.

PROBLEM 7.74

KNOWN: Diameter and initial and final temperatures of copper spheres quenched in an oil bath.

FIND: (a) Terminal velocity in bath, (b) Bath height.

SCHEMATIC:

ASSUMPTIONS: (1) Sphere descends at terminal velocity, (2) Uniform, but time varying, surface temperature.

PROPERTIES: Table A-1, Copper (350K): $\rho_{cu} = 8933 \text{ kg/m}^3$, $k = 398 \text{ W/m}\cdot\text{K}$, $c_p = 387 \text{ J/kg}\cdot\text{K}$; Table A-5, Oil ($T_\infty = 300\text{K}$): $\rho = 884 \text{ kg/m}^3$, $\mu = 0.486 \text{ N}\cdot\text{s/m}^2$, $k = 0.145 \text{ W/m}\cdot\text{K}$, $Pr = 6400$; ($T_s \approx 340\text{K}$): $\mu = 0.0531 \text{ N}\cdot\text{s/m}^2$.

ANALYSIS: (a) Force balance gives $C_D \left(\pi D^2 / 4 \right) \rho V^2 / 2 = (\rho_{cu} - \rho) g \pi D^3 / 6$,

$$C_D V^2 = \frac{4D}{3} \frac{\rho_{cu} - \rho}{\rho} g = \frac{4 \times 0.02 \text{ m}}{3} \frac{8933 - 884}{884} 9.8 \frac{\text{m}}{\text{s}^2} = 2.38 \text{ m}^2 / \text{s}^2.$$

An iterative solution is needed, where C_D is obtained from Fig. 7.8 with

$$Re_D = \frac{VD}{\nu} = \frac{0.02 \text{ m} (V)}{(0.486/884) \text{ m}^2 / \text{s}} = 36.4 V (\text{m/s}).$$

Convergence is achieved for $V \approx 1.1 \text{ m/s}$

for which $Re_D = 40$ and $C_D \approx 1.97$. Using the Whitaker expression

$$\overline{Nu}_D = 2 + \left(0.4 Re_D^{1/2} + 0.06 Re_D^{2/3} \right) Pr^{0.4} (\mu / \mu_s)^{1/4}$$

$$\overline{Nu}_D = 2 + \left(0.4 \times 40^{1/2} + 0.06 \times 40^{2/3} \right) (6400)^{0.4} (0.486 / 0.0531)^{1/4} = 189.2$$

$$\bar{h} = \overline{Nu}_D k / D = 189.2 \times 0.145 / 0.02 = 1357 \text{ W/m}^2 \cdot \text{K}.$$

To determine applicability of the lumped capacitance method, find $Bi = \bar{h} (r_o / 3) / k_{cu} =$

$1357 \text{ W/m}^2 \cdot \text{K} (0.01 \text{ m} / 3) / 398 \text{ W/m}\cdot\text{K} = 0.011$. Hence lumped capacitance method can be used; from Eq. 5.5,

$$t_f = \frac{(\rho c)_{cu} \pi D^3 / 6}{\bar{h} \pi D^2} \ln \frac{T_i - T_\infty}{T_f - T_\infty}$$

$$t_f = \frac{8933 \text{ kg/m}^3 \times 387 \text{ J/kg}\cdot\text{K} \times 0.02 \text{ m}}{1357 \text{ W/m}^2 \cdot \text{K} \times 6} \ln \frac{60}{20} = 9.33 \text{ s}.$$

Required tank height is $H = t_f \cdot V = 9.33 \text{ s} \times 1.1 \text{ m/s} = 10.3 \text{ m}$.

COMMENTS: (1) Whitaker correlation has been used well beyond its limits ($Pr \gg 380$). Hence estimate of \bar{h} is uncertain. (2) Since terminal velocity is not reached immediately,

$\bar{h} < 1357 \text{ W/m}^2 \cdot \text{K}$ and $t_f > 9.33 \text{ s}$.

PROBLEM 7.75

KNOWN: Velocity of plasma jet and initial particle velocity in a plasma spray coating process. Distance from particle injection to impact.

FIND: (a) Particle velocity and distance of travel as a function of time. Time-in-flight and particle impact velocity, (b) Convection heat transfer coefficient and time required to heat particle to melting point and to subsequently melt it.

SCHEMATIC:

ASSUMPTIONS: (1) Applicability of Stokes' law, (2) Constant particle and plasma properties, (3) Negligible influence of viscosity ratio in Whitaker correlation, (4) Negligible radiation effects, (5) Validity of lumped capacitance approximation.

ANALYSIS: (a) From Eqs. 7.50 and 7.55,

$$C_D = \frac{F_D}{A_f (\rho \bar{V}^2 / 2)} = \frac{24}{Re_D} = \frac{24}{\rho \bar{V} D_p / \mu}$$

where $\bar{V} \equiv V - V_p$ is the relative velocity and $A_f = \pi D_p^2 / 4$. Hence, the drag force on the particle is

$$F_D = 3\pi\mu D_p \bar{V} = m_p (dV_p / dt) = -m_p (d\bar{V} / dt)$$

Separating variables and integrating from the nozzle exit, where $V_p = 0$, $\bar{V} = V$ and $t = 0$,

$$\int_V^{\bar{V}} \frac{d\bar{V}}{\bar{V}} = -\frac{3\pi\mu D_p}{m_p} \int_0^t dt$$

$$\ln \frac{\bar{V}}{V} = -\frac{3\pi\mu D_p t}{m_p}$$

$$\bar{V} = V \exp(-3\pi\mu D_p t / m_p) = V - V_p$$

Hence,

$$V_p(t) = V \left[1 - \exp(-3\pi\mu D_p t / m_p) \right]$$

With $V_p = dx_p / dt$, it follows that

$$\int_0^L dx_p = \int_0^{t_f} V \left[1 - \exp(-3\pi\mu D_p t / m_p) \right] dt$$

Continued...

PROBLEM 7.75 (Cont.)

$$L = Vt_f - \frac{V m_p}{3\pi\mu D_p} \left[1 - \exp(-3\pi\mu D_p t_f / m_p) \right] \quad <$$

Substituting the prescribed values of D_p , L , V and the material properties, the foregoing equations yield

$$V_p = 166.7 \text{ m/s} \quad t_f = 0.0011 \text{ s} \quad <$$

(b) Assuming an average value of $\bar{V} = 315 \text{ m/s}$, the Reynolds number is

$$\text{Re}_D = \frac{315 \text{ m/s} \times 50 \times 10^{-6} \text{ m}}{5.6 \times 10^{-3} \text{ m}^2/\text{s}} = 2.81$$

From the Whitaker correlation,

$$\overline{\text{Nu}}_D = 2 + \left(0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Pr}^{0.4}$$

$$\overline{\text{Nu}}_D = 2 + \left(0.4 \times 2.81^{1/2} + 0.06 \times 2.81^{2/3} \right) (0.60)^{0.4} = 2.64$$

$$\bar{h} = 2.64 k / D_p = 2.64 (0.671 \text{ W/m} \cdot \text{K}) / 50 \times 10^{-6} \text{ m} = 35,400 \text{ W/m}^2 \cdot \text{K} \quad <$$

The two-step melting process involves (i) the time t_1 to heat the particle to its melting point and (ii) the time t_2 required to achieve complete melting. Hence, $t_m = t_1 + t_2$, where from Eq. 5.5,

$$t_1 = \frac{\rho_p D_p c_p}{6h} \ln \frac{T_i - T_\infty}{T_{mp} - T_\infty}$$

$$t_1 = \frac{3970 \text{ kg/m}^3 (50 \times 10^{-6} \text{ m}) 1560 \text{ J/kg} \cdot \text{K}}{6(35,400 \text{ W/m}^2 \cdot \text{K})} \ln \frac{(300 - 10,000)}{(2318 - 10,000)} = 3.4 \times 10^{-4} \text{ s}$$

Performing an energy balance for the second step, we obtain

$$\int_{t_1}^{t_m} q_{\text{conv}} dt = \Delta E_{\text{st}} = \rho_p V h_{sf}$$

Hence,

$$t_2 = \frac{\rho_p D_p}{6h} \frac{h_{sf}}{(T_\infty - T_{mp})} = \frac{3970 \text{ kg/m}^3 (50 \times 10^{-6} \text{ m})}{6(35,400 \text{ W/m}^2 \cdot \text{K})} \times \frac{3.577 \times 10^6 \text{ J/kg}}{(10,000 - 2318) \text{ K}} = 4.4 \times 10^{-4} \text{ s}$$

Hence,

$$t_m = (3.4 \times 10^{-4} + 4.4 \times 10^{-4}) \text{ s} = 7.8 \times 10^{-4} \text{ s} \quad <$$

and the prescribed value of L is sufficient to insure complete melting before impact.

COMMENTS: (1) Since $\text{Bi} = (\bar{h} r_p / 3) / k_p \approx 0.03$, use of the lumped capacitance approach is appropriate.

(2) With $\text{Re}_D = 2.81$, conditions are slightly outside the ranges associated with Stokes' law.

PROBLEM 7.76

KNOWN: Diameter, velocity, initial temperature and melting point of molten aluminum droplets. Temperature of helium atmosphere.

FIND: Maximum allowable separation between droplet injector and substrate.

SCHEMATIC:

ASSUMPTIONS: (1) Lumped capacitance approximation is valid, (2) Constant properties, (3) Negligible radiation.

PROPERTIES: Table A-4, Helium ($T_\infty = 300\text{K}$): $\nu = 122 \times 10^{-6} \text{ m}^2/\text{s}$, $\mu = 199 \times 10^{-7} \text{ N} \cdot \text{s}/\text{m}^2$, $k = 0.152 \text{ W}/\text{m} \cdot \text{K}$, $\text{Pr} = 0.68$. Helium ($T_s \approx 1000\text{K}$): $\mu_s = 446 \times 10^{-7} \text{ N} \cdot \text{s}/\text{m}^2$. Given, Aluminum: $\rho = 2500 \text{ kg}/\text{m}^3$, $c = 1200 \text{ J}/\text{kg} \cdot \text{K}$, $k = 200 \text{ W}/\text{m} \cdot \text{K}$.

ANALYSIS: With $\text{Re}_D = VD/\nu = 3 \text{ m/s} (5 \times 10^{-4} \text{ m}) / 122 \times 10^{-6} \text{ m}^2/\text{s} = 12.3$, the Whitaker correlation yields

$$\bar{h} = \frac{k}{D} \left[2 + \left(0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Pr}^{0.4} \left(\mu / \mu_s \right)^{1/4} \right]$$

$$\bar{h} = \frac{0.152 \text{ W}/\text{m} \cdot \text{K}}{0.0005 \text{ m}} \left\{ 2 + \left[0.4(12.3)^{1/2} + 0.06(12.3)^{2/3} \right] (0.68)^{0.4} \left(\frac{199}{446} \right)^{1/4} \right\} = 975 \text{ W}/\text{m}^2 \cdot \text{K}$$

The *time-of-flight* for the droplet to cool from 1100K to 933K may be obtained from Eq. 5.5.

$$t = \frac{\rho V c}{h A_s} \ln \frac{\theta_i}{\theta} = \frac{\rho c D}{6h} \ln \frac{T_i - T_\infty}{T_f - T_\infty}$$

$$t = \frac{(2500 \text{ kg}/\text{m}^3) 1200 \text{ J}/\text{kg} \cdot \text{K} (0.0005 \text{ m})}{6 \times 975 \text{ W}/\text{m}^2 \cdot \text{K}} \ln \left(\frac{800}{633} \right) = 0.06 \text{ s}$$

The maximum separation is therefore

$$L = V \times t = 3 \text{ m/s} \times 0.06 \text{ s} = 0.18 \text{ m} = 180 \text{ mm} \quad <$$

COMMENTS: (1) With $\text{Bi} = \bar{h}(D/6)/k = 4 \times 10^{-4}$, the lumped capacitance approximation is excellent. (2) With the surroundings assumed to be at $T_{\text{sur}} = T_\infty$ and a representative emissivity of $\epsilon = 0.1$ for molten aluminum, $h_r \leq \epsilon \sigma (T_i + T_\infty)(T_i^2 + T_\infty^2) \approx 10 \text{ W}/\text{m}^2 \cdot \text{K} \ll \bar{h} = 975 \text{ W}/\text{m}^2 \cdot \text{K}$. Hence, radiation is, in fact, negligible.

PROBLEM 7.77

KNOWN: Method to manufacture small diameter droplets. Properties of $D = 75 \mu\text{m}$ diameter particles ejected into air. Air temperature and pressure, initial particle temperature. Desired temperature of drop upon impact of a substrate.

FIND: (a) Terminal velocity of the droplets, (b) Separation distance between droplet injection location and substrate so that the droplets impact the substrate at $T_2 = 120^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible radiation heat transfer, (2) lumped capacitance thermal response, (3) Negligible microscale heat transfer effects.

PROPERTIES: Table A.4, air: $(T_f \approx [(T_i + T_2)/2 + T_\infty]/2) = [(150^\circ\text{C} + 120^\circ\text{C})/2 + 25^\circ\text{C}]/2 = 80^\circ\text{C} \approx 353 \text{ K}$; $\rho = 0.9876 \text{ kg/m}^3$, $\nu = 21.25 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.03023 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.6994$. $(\bar{T}_s = (150^\circ\text{C} + 120^\circ\text{C})/2 = 135^\circ\text{C} = 408 \text{ K}$; $\mu_s = 2.334 \times 10^{-5} \text{ N}\cdot\text{s/m}^2$. $(T_\infty = 25^\circ\text{C} = 298 \text{ K})$: $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.02614 \text{ W/m}\cdot\text{K}$, $\mu = 1.836 \times 10^{-5} \text{ N}\cdot\text{s/m}^2$, $\text{Pr} = 0.7075$.

ANALYSIS:

(a) A force balance on the particle yields

$$\forall \rho_p g = C_D A_f (\rho V^2 / 2) \quad (1)$$

$$\text{where } \forall = \frac{4}{3} \pi (D_p/2)^3 = \frac{4}{3} \times \pi \times (75 \times 10^{-6} \text{ m})^3 = 220.9 \times 10^{-15} \text{ m}^3$$

$$A_f = \pi (D_p/2)^2 = \pi \times (75 \times 10^{-6} \text{ m})^2 = 4.42 \times 10^{-9} \text{ m}^2$$

We also know

$$\text{Re}_D = \frac{V D_p}{\nu} = \frac{V \times 75 \times 10^{-6} \text{ m}}{21.25 \times 10^{-6} \text{ m}^2/\text{s}} = 3.53 (\text{s/m}) \times V \quad (2)$$

The correct velocity will yield values of C_D and Re_D that are consistent with Figure 7.8. A trial-and-error solution yields (using properties at \bar{T}_f)

$$V \approx 0.30 \text{ m/s}, \text{Re}_D = 1.06, C_D = 24.2 \text{ (} C_D \text{ from Figure 7.8} \approx 25) \quad <$$

(b) Using the Whitaker correlation with properties evaluated at T_∞ ,

$$\text{Re}_D = 0.3 \text{ m/s} \times 75 \times 10^{-6} \text{ m} / 1.571 \times 10^{-5} \text{ m}^2/\text{s} = 1.43$$

Therefore,

Continued....

PROBLEM 7.77 (Cont.)

$$\overline{\text{Nu}}_D = 2 + \left[0.4\sqrt{1.43} + 0.06 \times 1.43^{2/3} \right] \times 0.7075^{0.4} \times \left(\frac{1.836}{2.334} \right)^{1/4} = 2.45$$

$$\bar{h}_D = \overline{\text{Nu}}_D k / D_p = 2.45 \times 0.02614 \text{ W/m} \cdot \text{K} / 75 \times 10^{-6} \text{ m} = 854 \text{ W/m}^2 \cdot \text{K}$$

Using Equation 5.6 with $A_s = 4 \times \pi \times (75 \times 10^{-6} \text{ m}/2)^2 = 17.7 \times 10^{-9} \text{ m}^2$,

$$\frac{T_2 - T_\infty}{T_1 - T_\infty} = \frac{120 - 25}{150 - 25} = 0.76 = \exp \left[- \left(\frac{854 \text{ W/m}^2 \cdot \text{K} \times 17.7 \times 10^{-9} \text{ m}^2}{2200 \text{ kg/m}^3 \times 220.9 \times 10^{-15} \text{ m}^3 \times 700 \text{ J/kg} \cdot \text{K}} \right) \times t \right]$$

yielding $t = 6.20 \times 10^{-3} \text{ s} = 6.2 \text{ ms}$. The separation distance, L , is therefore

$$L = 0.30 \text{ m/s} \times 6.2 \times 10^{-3} \text{ s} = 1.86 \times 10^{-3} \text{ m} = 1.86 \text{ mm} \quad <$$

COMMENTS: (1) The maximum possible radiation heat transfer coefficient is associated with the initial particle temperature and an emissivity of unity. Assuming a surroundings temperature of $25^\circ\text{C} = 298 \text{ K}$, we find a radiation heat transfer coefficient of $h_r = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (423 + 298) \text{ K} \times (423^2 + 298^2) \text{ K}^2 = 11 \text{ W/m}^2 \cdot \text{K}$. Therefore, radiation heat transfer is negligible. (2) The terminal velocity of the very small spherical particle is very low. This is because the surface area to weight ratio of a sphere is inversely proportional to the sphere diameter. As the sphere becomes small, drag forces become relatively large at relatively low velocities. (3) The Whitaker correlation has been extrapolated outside of its recommended range of application. However, we know that the limiting value of the average Nusselt number is two. (4) The sphere is very small and the density of the sphere is relatively low. The lumped capacitance assumption is likely to be valid.

PROBLEM 7.78

KNOWN: Velocity and temperature of combustion gases. Diameter and emissivity of thermocouple junction. Combustor temperature.

FIND: (a) Time to achieve 98% of maximum thermocouple temperature rise, (b) Steady-state thermocouple temperature, (c) Effect of gas velocity and thermocouple emissivity on measurement error.

SCHEMATIC:

ASSUMPTIONS: (1) Validity of lumped capacitance analysis, (2) Constant properties, (3) Negligible conduction through lead wires, (4) Radiation exchange between small surface and a large enclosure (parts b and c).

PROPERTIES: Thermocouple (given): $0.1 \leq \varepsilon \leq 1.0$, $k = 100 \text{ W/m}\cdot\text{K}$, $c = 385 \text{ J/kg}\cdot\text{K}$, $\rho = 8920 \text{ kg/m}^3$; Gases (given): $k = 0.05 \text{ W/m}\cdot\text{K}$, $\nu = 50 \times 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 0.69$.

ANALYSIS: (a) If the lumped capacitance analysis may be used, it follows from Equation 5.5 that

$$t = \frac{\rho V c}{h A_s} \ln \frac{T_i - T_\infty}{T - T_\infty} = \frac{D \rho c}{6h} \ln(50).$$

Neglecting the viscosity ratio correlation for variable property effects, use of $V = 5 \text{ m/s}$ with the Whitaker correlation yields

$$\overline{\text{Nu}}_D = (\overline{h}D/k) = 2 + \left(0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3}\right) \text{Pr}^{0.4} \quad \text{Re}_D = \frac{VD}{\nu} = \frac{5 \text{ m/s}(0.001 \text{ m})}{50 \times 10^{-6} \text{ m}^2/\text{s}} = 100$$

$$\overline{h} = \frac{0.05 \text{ W/m}\cdot\text{K}}{0.001 \text{ m}} \left[2 + \left(0.4(100)^{1/2} + 0.06(100)^{2/3}\right)(0.69)^{0.4} \right] = 328 \text{ W/m}^2 \cdot \text{K}$$

Since $\text{Bi} = \overline{h}(r_o/3)/k = 5.5 \times 10^{-4}$, the lumped capacitance method may be used. Hence,

$$t = \frac{0.001 \text{ m} (8920 \text{ kg/m}^3) 385 \text{ J/kg}\cdot\text{K}}{6 \times 328 \text{ W/m}^2 \cdot \text{K}} \ln(50) = 6.83 \text{ s} \quad <$$

(b) Performing an energy balance on the junction and evaluating radiation exchange from Equation 1.7, $q_{\text{conv}} = q_{\text{rad}}$. Hence, with $\varepsilon = 0.5$,

$$\overline{h} A_s (T_\infty - T) = \varepsilon A_s \sigma (T^4 - T_c^4)$$

$$(1000 - T) \text{ K} = \frac{0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{328 \text{ W/m}^2 \cdot \text{K}} [T^4 - (400)^4] \text{ K}^4.$$

$$T = 936 \text{ K} \quad <$$

(c) Using the *IHT First Law Model* for a *Solid Sphere* with the appropriate *Correlation* for external flow from the Tool Pad, parametric calculations were performed to determine the effects of V and ε , and the following results were obtained.

Continued...

PROBLEM 7.78 (Cont.)

Since the temperature recorded by the thermocouple junction increases with increasing V and decreasing ϵ , the measurement error, $T_\infty - T$, decreases with increasing V and decreasing ϵ . The error is due to net radiative transfer from the junction (which depresses T) and hence should decrease with decreasing ϵ . For a prescribed heat loss, the temperature difference ($T_\infty - T$) decreases with decreasing convection resistance, and hence with increasing $h(V)$.

COMMENTS: To infer the actual gas temperature (1000 K) from the measured result (936 K), correction would have to be made for radiation exchange with the cold surroundings.

PROBLEM 7.79

KNOWN: Diameter, emissivity and temperature of a thermocouple junction exposed to hot gases flowing through a duct of prescribed surface temperature.

FIND: (a) Relative magnitudes of gas and thermocouple temperatures if the duct surface temperature is less than the gas temperature, (b) Gas temperature for prescribed conditions, (c) Effect of Velocity and emissivity on measurement error.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Junction is diffuse-gray, (3) Duct forms a large enclosure about the junction, (4) Negligible heat transfer by conduction through the thermocouple leads, (5) Gas properties are those of atmospheric air.

PROPERTIES: Table A-4, Air ($T_g \approx 650$ K, 1 atm): $\nu = 60.21 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0497 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.690$, $\mu = 322.5 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$; Air ($T_j = 593$ K, 1 atm): $\mu = 304 \times 10^{-7} \text{ N}\cdot\text{s/m}^2$.

ANALYSIS: (a) From an energy balance on the thermocouple junction, $q_{\text{conv}} = q_{\text{rad}}$. Hence,

$$\bar{h}A(T_g - T_j) = \varepsilon\sigma A(T_j^4 - T_s^4) \quad \text{or} \quad T_g - T_j = \frac{\varepsilon}{\bar{h}}\sigma(T_j^4 - T_s^4).$$

If $T_s < T_j$, it follows that $T_j < T_g$. <

(b) Neglecting the variable property correction, $(\mu/\mu_s)^{1/4} = (322.5/304)^{1/4} = 1.01 \approx 1.00$, and using

$$\text{Re}_D = \frac{VD}{\nu} = \frac{3 \text{ m/s}(0.002 \text{ m})}{60.21 \times 10^{-6} \text{ m}^2/\text{s}} = 100$$

the Whitaker correlation for a sphere gives

$$\bar{h} = \frac{0.0497 \text{ W/m}\cdot\text{K}}{0.002 \text{ m}} \left\{ 2 + \left[0.4(100)^{1/2} + 0.06(100)^{2/3} \right] (0.69)^{0.4} \right\} = 163 \text{ W/m}^2\cdot\text{K}.$$

Hence

$$(T_g - 593 \text{ K}) = \frac{0.6}{163 \text{ W/m}^2\cdot\text{K}} 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \left[(593 \text{ K})^4 - (448 \text{ K})^4 \right] = 17 \text{ K}$$

$$T_g = 610 \text{ K} = 337^\circ\text{C}. <$$

(c) With T_g fixed at 610 K, the IHT First Law Model was used with the Correlations and Properties Tool Pads to compute the measurement error as a function of V and ε .

Continued...

PROBLEM 7.79 (Cont.)

Since the convection resistance decreases with increasing V , the junction temperature will approach the gas temperature and the measurement error will decrease. Since the depression in the junction temperature is due to radiation losses from the junction to the duct wall, a reduction in ϵ will reduce the measurement error.

COMMENTS: In part (b), calculations could be improved by evaluating properties at 610 K (instead of 650 K).

PROBLEM 7.80

KNOWN: Diameter and emissivity of a thermocouple junction exposed to hot gases of prescribed velocity and temperature flowing through a duct of prescribed surface temperature.

FIND: (a) Thermocouple reading for gas at atmospheric pressure, (b) Thermocouple reading when gas pressure is doubled.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Junction is diffuse-gray, (3) Duct forms a large enclosure about junction, (4) Negligible heat loss by conduction through thermocouple leads, (5) Gas properties are those of air, (6) Perfect gas behavior.

PROPERTIES: Table A-4, Air ($T_g = 773\text{ K}$, 1 atm): $\nu = 80.5 \times 10^{-6}\text{ m}^2/\text{s}$, $k = 0.0561\text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.705$.

ANALYSIS: (a) Performing an energy balance on the junction

$$\dot{q}_{\text{conv}} = \dot{q}_{\text{rad}}$$

$$(g \rightarrow j) \quad (j \rightarrow s)$$

$$\bar{h}A(T_g - T_j) = \varepsilon\sigma A(T_j^4 - T_s^4).$$

Neglecting the variable property correction, $(\mu/\mu_s)^{1/4}$, and using

$$\text{Re}_D = \frac{VD}{\nu} = \frac{3\text{ m/s} \times 0.002\text{ m}}{80.5 \times 10^{-6}\text{ m}^2/\text{s}} = 74.5$$

the Whitaker correlation for a sphere gives,

$$\bar{h} = \frac{0.0561\text{ W/m}\cdot\text{K}}{0.002\text{ m}} \left\{ 2 + \left[0.4(74.5)^{1/2} + 0.06(74.5)^{2/3} \right] (0.705)^{0.4} \right\} = 166\text{ W/m}^2\cdot\text{K}.$$

$$166(773 - T_j) = 0.6 \times 5.67 \times 10^{-8} [T_j^4 - (473)^4]$$

and from a trial-and-error solution,

$$T_j \approx 726\text{ K}.$$

(b) Assuming all properties other than ν to remain constant with a change in pressure, $\uparrow p$ by 2 will $\downarrow \nu$ by 2 and hence $\uparrow \text{Re}_D$ by 2, giving $\text{Re}_D = 149$. Hence

$$\bar{h} = \frac{0.0561}{0.002} \left\{ 2 + \left[0.4(149)^{1/2} + 0.06(149)^{2/3} \right] (0.705)^{0.4} \right\} = 216\text{ W/m}^2\cdot\text{K}.$$

$$216(773 - T_j) = 0.6 \times 5.67 \times 10^{-8} [T_j^4 - (473)^4]$$

and from a trial-and-error solution

$$T_j \approx 735\text{ K}.$$

COMMENTS: The thermocouple error will \downarrow with $\uparrow h$, which \uparrow with $\uparrow p$.

PROBLEM 7.81

KNOWN: Velocity and temperature of helium flow over graphite coated uranium oxide pellets. Pellet and coating diameters and thermal conductivity. Surface temperature of coating.

FIND: (a) Rate of heat transfer, (b) Volumetric generation rate in pellet and pellet surface temperature, (c) Radial temperature distribution in pellet, (d) Effect of gas velocity on center and surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady conduction in the radial direction, (2) Uniform generation, (3) Constant properties, (4) Negligible radiation, (5) Negligible contact resistance.

PROPERTIES: Table A.4, Helium ($T_\infty = 500$ K, 1 atm): $\nu = 290 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.22 \text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.67$, $\mu = 283 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2$; ($T_{s,o} = 1300$ K, with extrapolation): $\mu = 592 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2$.

ANALYSIS: (a) The heat transfer rate is $q = \bar{h}A_s(T_{s,o} - T_\infty)$, where the convection coefficient can be estimated from $\overline{\text{Nu}}_D = 2 + \left(0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3}\right) \text{Pr}^{0.4} (\mu_\infty/\mu_s)^{1/4}$, where

$$\text{Re}_D = \frac{VD_o}{\nu} = \frac{20 \text{ m/s} \times 0.012 \text{ m}}{290 \times 10^{-6} \text{ m}^2/\text{s}} = 828$$

$$\overline{\text{Nu}}_D = 2 + \left[0.4(828)^{1/2} + 0.06(828)^{2/3}\right](0.67)^{0.4}(283/592)^{1/4} = 13.9$$

$$\bar{h} = \frac{k}{D_o} \overline{\text{Nu}}_D = \frac{0.22 \text{ W/m}\cdot\text{K}}{0.012 \text{ m}} \times 13.9 = 255 \text{ W/m}^2 \cdot \text{K}.$$

$$\text{Hence, } q = 255 \text{ W/m}^2 \cdot \text{K} \times \pi (0.012 \text{ m})^2 (1300 - 500) \text{ K} = 92.2 \text{ W}.$$

(b) The volumetric heat rate in the pellet is

$$\dot{q} = \frac{q}{\pi D_i^3/6} = \frac{6 \times 92.2 \text{ W}}{\pi (0.01 \text{ m})^3} = 1.76 \times 10^8 \text{ W/m}^3$$

The inner surface temperature of the coating is equal to the pellet surface temperature,

$$T_{s,i} - T_{s,o} = q \frac{1}{4\pi k_g} \left(\frac{1}{r_i} - \frac{1}{r_o} \right) = \frac{92.2 \text{ W}}{4\pi (2 \text{ W/m}\cdot\text{K})} \left(\frac{1}{0.005 \text{ m}} - \frac{1}{0.006 \text{ m}} \right) = 122.3 \text{ K}$$

$$T_{s,i} = 1300 \text{ K} + 122.3 \text{ K} = 1422 \text{ K}.$$

(c) The heat equation for the spherical pellet reduces to

$$\frac{k_p}{r^2} \frac{d}{dr} \left(r^2 \frac{dT}{dr} \right) = -\dot{q}$$

Integrating twice,

$$r^2 \frac{dT}{dr} = -\frac{\dot{q}}{3k_p} r^3 + C_1 \quad \frac{dT}{dr} = -\frac{\dot{q}}{3k_p} r + \frac{C_1}{r^2}$$

Continued...

PROBLEM 7.81 (Cont.)

$$T = -\frac{\dot{q}}{6k_p}r^2 - \frac{C_1}{r} + C_2.$$

Applying boundary conditions,

$$r = 0: \quad \left. \frac{dT}{dr} \right|_{r=0} = 0 \quad \rightarrow \quad C_1 = 0$$

$$r = r_i: \quad T(r_i) = T_{s,i} \quad \rightarrow \quad C_2 = T_{s,i} + \left(\dot{q}/6k_p \right) r_i^2.$$

Hence the temperature distribution is

$$T(r) = T_{s,i} + \left(\dot{q}/6k_p \right) (r_i^2 - r^2) = T(0) - \left(\dot{q}/6k_p \right) r^2 \quad <$$

where the temperature at the pellet center is $T(0) = T_{s,i} + \left(\dot{q}/6k_p \right) r_i^2$.

For the prescribed conditions,

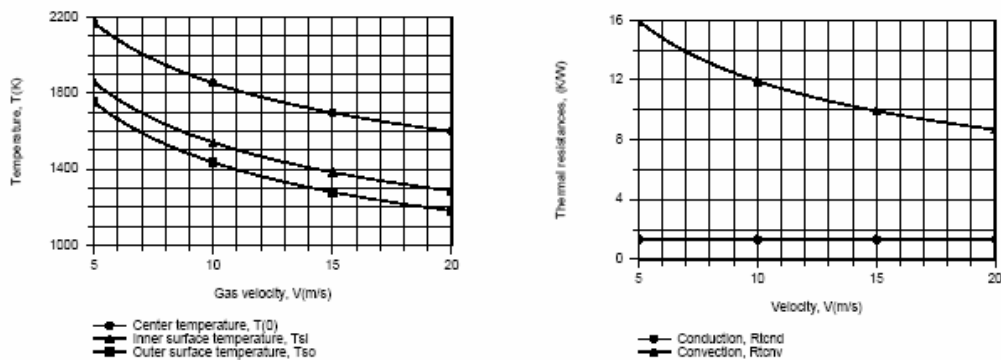

$$T(0) = 1422 \text{ K} + \left(1.76 \times 10^8 \text{ W/m}^3 / 6 \times 2 \text{ W/m} \cdot \text{K} \right) (0.005 \text{ m})^2 = 1789 \text{ K}.$$

(d) With $\dot{q} = 1.5 \times 10^8 \text{ W/m}^3$, parametric calculations were performed using the IHT Model for *One-Dimensional, Steady-State Conduction* in a sphere, with the surface condition, $q''(r_i) = (T_{s,i} - T_\infty)/R_{t,i}$,

where the total thermal resistance, $R_{t,i} = R_{t,i}''/4\pi r_i^2$, is

$$R_{t,i} = R_{t,cnd} + R_{t,conv} = \frac{(1/r_i) - (1/r_o)}{4\pi k_p} + \frac{1}{4\pi r_o^2 h}$$

The *Correlations and Properties* Tool Pads were used to evaluate the convection coefficient, and the following results were obtained.

As expected, all temperatures increase with decreasing V , while fixed values of \dot{q} , and hence $q(r_i)$, and $R_{t,cnd}$ provide fixed values of $(T(0) - T_{s,i})$ and $(T_{s,i} - T_{s,o})$, respectively.

COMMENTS: In a more detailed analysis, radiation heat transfer, which would decrease the temperatures, should be considered.

PROBLEM 7.82

KNOWN: Initial temperature, dimensions and properties of chip and solder connectors. Velocity, temperature and properties of liquid.

FIND: (a) Ratio of time constants (chip-to-solder), (b) Chip-to-solder temperature difference after 0.25s of heating.

SCHEMATIC:

ASSUMPTIONS: (1) Solder balls and chips are spatially isothermal, (2) Negligible heat transfer from sides of chip, (3) Top and bottom surfaces of chip act as flat plates in turbulent parallel flow, (4) Heat transfer from solder balls may be approximated as that from an isolated sphere, (5) Constant properties.

PROPERTIES: Given. Dielectric liquid: $k = 0.064 \text{ W/m}\cdot\text{K}$, $\nu = 10^{-6} \text{ m}^2/\text{s}$, $\text{Pr} = 25$; Silicon chip: $k = 150 \text{ W/m}\cdot\text{K}$, $\rho = 2300 \text{ kg/m}^3$, $c_p = 700 \text{ J/kg}\cdot\text{K}$; Solder ball: $k = 40 \text{ W/m}\cdot\text{K}$, $\rho = 10,000 \text{ kg/m}^3$, $c_p = 150 \text{ J/kg}\cdot\text{K}$.

ANALYSIS: (a) From Eq. 5.7, the thermal time constant is $\tau_t = (\rho \nabla c / \bar{h} A_s)$. Hence,

$$\frac{\tau_{t,\text{ch}}}{\tau_{t,\text{sld}}} = \frac{(\rho c)_{\text{ch}} (L^2 t)}{2 \bar{h}_{\text{ch}} L^2} \frac{\bar{h}_{\text{sld}} (\pi D^2)}{(\rho c)_{\text{sld}} (\pi D^3 / 6)} = 3 \frac{t}{D} \frac{(\rho c)_{\text{ch}} \bar{h}_{\text{sld}}}{(\rho c)_{\text{sld}} \bar{h}_{\text{ch}}}$$

The convection coefficient for the chip may be obtained from Eq. 7.38 with $A = 0$, with

$$\text{Re}_L = VL/\nu = 0.2 \text{ m/s} \times 0.01 \text{ m} / 10^{-6} \text{ m}^2/\text{s} = 2000.$$

$$\bar{h}_{\text{ch}} = \frac{0.064 \text{ W/m}\cdot\text{K}}{0.01 \text{ m}} (0.037)(2000)^{4/5} (25)^{1/3} = 302 \text{ W/m}^2\cdot\text{K}$$

The convection coefficient for the solder may be obtained from Eq. 7.56, with $\text{Re}_D = VD/\nu$

$$= 0.2 \text{ m/s} \times 0.001 \text{ m} / 10^{-6} \text{ m}^2/\text{s} = 200. \text{ Neglecting the effect of the viscosity ratio,}$$

$$\bar{h}_{\text{sld}} = \frac{0.064 \text{ W/m}\cdot\text{K}}{0.001 \text{ m}} \left\{ 2 + \left[0.4(200)^{1/2} + 0.06(200)^{2/3} \right] (25)^{0.4} \right\} = 1916 \text{ W/m}^2\cdot\text{K}$$
